

Abstracts from the 37th Annual Meeting of the Society of General Internal Medicine

SCIENTIFIC ABSTRACTS

"A ONE-STOP SHOP:" PERCEIVED BENEFITS OF DIABETES GROUP VISITS IN THE SAFETY NET CLINIC SETTING Arshiya A. Baig¹; Amanda Benitez¹; Amanda Campbell²; Cynthia T. Schaefer^{3,2}; Loretta J. Heuer^{4,2}; Michael T. Quinn¹; Deborah L. Burnett¹; Marshall Chin¹. ¹University of Chicago, Chicago, IL; ²MidWest Clinicians' Network, Lansing, MI; ³University of Evansville, Evansville, IN; ⁴North Dakota State University, Fargo, ND. (*Tracking ID #1934849*)

BACKGROUND: Diabetes group visits, shared appointments in which patients with diabetes receive self-management education in a group setting and have a medical visit, are an innovative and promising way to deliver diabetes care. The group visit model may be especially promising in safety net clinics where many patients with diabetes in underserved settings receive their care. However, little is known about safety net providers' perceptions of diabetes group visits in the community health center setting.

METHODS: The research team conducted site visits at community health centers across the Midwest to assess their experiences in providing diabetes group visits. Site visits were conducted at centers that had implemented diabetes group visits in the past or currently had them. Two members of the research team interviewed health center personnel at each site regarding their diabetes group visit program. Health center personnel included chief executive officers, medical and nursing directors, care coordinators, physicians, nurses, physician assistants, diabetes educators, mental health professionals, dietitians, medical assistants, pharmacists, and other recommended staff members who were familiar with the diabetes group visits at the site. Interviewees were asked about the benefits of having diabetes group visits at their site. All interviews were audio-recorded and transcribed. Systematic qualitative analysis techniques were used to identify the range and consistency of opinions and experiences across interviewees.

RESULTS: The research team visited five health center sites across four states in the Midwest and conducted a total of 26 interviews with health center personnel. One site was rural, three were urban, and one was suburban. Health center personnel noted many benefits of group visits to the health center, providers, and patients. The benefits of group visits to the health center included an alignment of the group visit model with the mission of becoming a patient centered medical home, the ability to bill for group visits, and an efficient way to improve guideline-driven care for patients. Provider benefits from group visits included boost to provider morale, opportunities to collaborate with multidisciplinary

colleagues, and having more time to focus on other medical concerns during patient's routine follow-up visits. Patients derived many benefits, including receiving education and medical care in a single appointment, e.g. "the one-stop shop" or "best bang for your buck," the opportunity to obtain social support and enhanced motivation through peers, and the potential to improve their clinical outcomes by attending group visits.

CONCLUSIONS: Diabetes group visits can offer many unique benefits to safety net clinics by providing patient-centered care, boosting provider morale, increasing multidisciplinary collaboration, and offering patients the convenience of combining an educational session with a primary care appointment. Further studies need to assess best practices in implementing group visits in health centers and assess their impact on patient outcomes.

"A PLACE AT THE TABLE:" EVALUATION OF COMMUNITY MEMBERS' EXPERIENCES AND EXPECTATIONS FOR ACADEMIC-COMMUNITY PARTNERSHIPS IN HIV/AIDS RESEARCH Stella Safo¹; Chinazo Cunningham^{3,2}; Alice Beckman²; Joanna L. Starrels^{3,2}. ¹Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine, Bronx, NY; ³Montefiore Medical Center, Bronx, NY. (*Tracking ID #1937992*)

BACKGROUND: The foundation of community based participatory research (CBPR) is collaboration between academic researchers and members of a given community. Community advisory boards (CABs) are one mechanism through which academic-community partnerships are formed, but current research about CAB members' opinions on barriers to collaborations with academics is limited. This qualitative study examined CAB members' expectations and experiences in working with academic researchers in the field of HIV/AIDS.

METHODS: We conducted 10 semi-structured one-on-one interviews with individuals serving on a CAB for HIV-related research at an urban academic medical center. Participating CAB members were leaders of HIV/AIDS community organizations in Bronx, NY and had at least 5 years of experience working in the field of HIV/AIDS. Interview questions focused on participants' current and previous experiences with academic research and researchers, trust in these relationships, and best practices for collaboration. Interviews were professionally transcribed and data was analyzed using a grounded theory approach. Transcript data were coded by two independent researchers using NVivo 10 software and analyzed in an iterative process to identify emergent themes.

RESULTS: CAB members described positive aspects of inclusion on a CAB, including improved access to information about current HIV topics and the opportunity to help shape HIV research in their communities. However, CAB members also described negative previous interactions with researchers, and a lack of trust in researchers themselves or in the process of conducting research with academic institutions. A major reason for distrust was that power was perceived as unequal,

often resulting in miscommunications that led to lasting negative impressions. For example, several members recounted researchers approaching subjects directly, without informing the home organization about the intended study focus. In addition, CAB members felt that expectations for collaboration were not clearly established. CAB members also shared suggestions for improving the collaborative process, including outlining expectations from the outset of the partnership and holding CAB meetings in the community rather than at the academic center.

CONCLUSIONS: We identified complex interpersonal issues in relationships between CAB members and academic partners, particularly around trust and power-sharing in conducting HIV/AIDS research. Our findings suggest that academic-community collaborations could be enhanced by improving transparency, explicitly addressing issues of distrust from previous negative experiences, and ensuring equitable power-sharing among researchers and community members. Further research should be conducted to determine the best ways to engage and maximize the impact of CABs in the field of HIV/AIDS.

"ARE YOU AFRAID OF PNEUMONIA?" PATIENTS' FEEDBACK ON THE DEVELOPMENT OF AN EDUCATIONAL VIDEO ABOUT PNEUMOCOCAL VACCINATION Kenzie A. Cameron; Tiffany Brown; Shira N. Goldman. Northwestern University, Chicago, IL. (*Tracking ID #1926320*)

BACKGROUND: Invasive pneumococcal disease causes a mortality burden among people age 65 and older. Consequently, the Advisory Committee on Immunization Practices recommends pneumococcal vaccination (PnVx) for these adults. However, national rates of PnVx for those age 65 and older are just over 60 %. Further, racial and ethnic disparities in vaccination remain: 2011 estimates reported 66.5 % vaccination among whites age 65 and older, as compared to only 47.6 % among blacks. Informed by our previous research on perceptions toward PnVx among unvaccinated adults, we developed a 2 min patient education video targeted at unvaccinated 65 and 66 year olds to encourage uptake of PnVx. Our objective was to discuss patient attitudes toward vaccination and beliefs about pneumonia, and obtain feedback regarding suggested revisions for the video.

METHODS: At an academic general internal medicine clinic, we queried the electronic health record to identify 65 and 66 year old black and white patients who had no record of receipt or refusal of PnVx. In early 2013, patients were recruited to participate in race-concordant focus groups. Prior to the start of each group, participants completed a brief demographic survey, which included questions regarding past experience with pneumonia and PnVx. During the audio-recorded focus group, we asked participants to describe pneumonia, tell us what they knew about PnVx, and specify what they would want included in educational messages about the vaccine.

RESULTS: Four white and two black patient focus groups were conducted, with a total of 26 participants. Mean age was 65.9 (3.1), 81 % were female, 88 % had attended college, and 39 % reported receipt of PnVx. Based on our previous research, the video included a strong focus on individual susceptibility to pneumonia, as well as personal testimonial from a black man about his late wife who did not think she needed PnVx. Black patients in particular noted that the testimonial was a persuasive part of the video. Participant response to the video was positive, with some individuals indicating a newly found motivation to consider vaccination (e.g., "Even though I refused the pneumonia vaccine already, next time I see my provider, I'm going to tell her I want to get shot," and "I'm going to go get my shot now. I didn't realize how potent and prevalent it is."). However, some participants felt that the video focused too heavily on severity and fear (e.g., "I find it dire. Very uncomfortable watching it"). The video included an appeal to consistency and the need for vaccination across the lifespan ("Just as you got vaccinated as a child, you need to receive important lifesaving vaccines as an adult"), which was met with favorable responses from participants. Several participants highlighted the importance of discussing PnVx with their providers and indicated that viewing this video prior to an appointment could provide an opportunity for such discussion (e.g., "I might talk to my doctor. I don't know if she could persuade me to get it. Maybe she could explain it to me differently").

CONCLUSIONS: Feedback from the focus group participants led to revisions to the patient education video, specifically with regard to reducing the number of times the severity of pneumonia was stressed. The personal narrative was retained as numerous individuals spoke of its persuasiveness, as was a focus on personal susceptibility to pneumonia and the need for vaccination across the lifespan. The revised video is under 2 min long, has been integrated into our electronic health record system, and is being tested at the point-of-care to assess its effect on receipt of PnVx among patients eligible for vaccination.

"BEYOND OUR CONTROL": HOW ORGANIZATIONAL CONTEXT IMPACTS PERFORMANCE MEASUREMENT Molly Harrod¹; Jane Forman¹; Claire Robinson¹; Adam Tremblay^{2,3}; Leo Greenstone^{2,3}; Eve A. Kerr^{1,3}. ¹VHA Ann Arbor Health Care System, Ann Arbor, MI; ²VHA Ann Arbor Health Care System, Ann Arbor, MI; ³University of Michigan, Ann Arbor, MI. (*Tracking ID #1937968*)

BACKGROUND: The Patient Centered Medical Home (PCMH) model requires a shift from a physician centric to a team-based approach to care, as well as improvement in process measures that reflect PCMH goals. As a result, as primary care (PC) providers are learning to work in teams, they also must learn how to change their clinic processes to meet PCMH-specific performance measures. The Veterans Health Administration (VHA) transitioned over 900 PC sites to a PCMH model beginning in 2010 and has implemented national metrics of PCMH success that include same day access and continuity with the patient's usual provider. One large VHA health system implemented a coaching model to help newly formed PC teams redesign their delivery processes to improve access and continuity measures. This study examines how these PC teams discussed and responded to these measures during their coaching sessions.

METHODS: Nine of 20 PC teams were longitudinally observed during coaching sessions (25+ hours) that entailed discussion of both performance measures and processes to improve measure results. Conversations and interactions were recorded via hand-written field notes. We analyzed data using a grounded approach.

RESULTS: As PC teams reviewed their access and continuity measures, two predominant, and often overlapping, themes emerged: lack of control and lack of consistency across the organization. PC teams felt they did not have control over processes both within and outside PC. For example, a centralized call center with variable understandings of PC redesign continued to refer patients to the Emergency Department even though PC providers had open appointments within their schedules, thus impacting continuity. A lack of consistency across the organization as a whole was apparent given that many of the other departments did not change their patient care processes to align with PCMH goals. For example, inpatient physicians followed a rule that patients discharged from the inpatient setting needed "follow-up with primary care physician in 7–10 days". Because this 7–10 day mandate meant fewer open slots in a PC provider's clinic, it decreased same day access. Thus, organizational processes were often working against one another resulting measures that were not reflective of all the changes.

CONCLUSIONS: Improving even straightforward performance measures, like same-day access, requires an understanding of the entire practice context. In our study, measurement results that fell short of goals reflected the organizational inconsistency of processes that impacted individual measures. It is important to develop processes designed to meet PACT goals across the organization rather than within each team or department. As more PC practices become part of Accountable Care Organizations and are assessed using these and other performance measures, a better understanding of what is being measured, how these measures reflect patient-centered care, unintended consequences of measures and other organizational actions, and how to align organizational performance goals is needed so that organizational performance reflects true quality of care and patient-centeredness, and not just performance on individual metrics.

"CODE R": INTRODUCTION OF A HOSPITAL-WIDE PEER REVIEW PROCESS TO ASSESS RESIDENTS' POTENTIAL IMPACT ON PATIENT SAFETY AND QUALITY Daniel I. Kim^{1,3}; Lawrence Loo²; Huy Au^{1,3}; Ramiz Fargo^{1,3}; Roger C. Garrison^{1,3}; Gary Thompson^{1,3}; Minho Yu^{2,3}. ¹University of California, Riverside, Riverside, CA; ²Loma Linda University Medical Center, Loma Linda, CA; ³Riverside County Regional Medical Center, Moreno Valley, CA. (*Tracking ID #1928321*)

BACKGROUND: The hospital physician peer review process is a valuable method of reviewing physician competency and safety, but it is rarely used to evaluate residents, who frequently work under indirect supervision. In 2008, our institution introduced "Code R" to our peer review process to highlight the potential resident involvement in cases undergoing peer review. To our knowledge, there are no published studies that utilize a hospital-wide peer review process to evaluate and track residents in training. Our study sought to characterize resident errors using the ACGME's core competencies to determine whether interns are more prone to errors than senior residents and to see if there were patterns of resident errors by time of day or month of year.

METHODS: The study is a retrospective review of all peer review cases recorded from 2008 to 2011 by the Quality Management department at Riverside County Regional Medical Center, an academic safety net institution. The institutional peer

review process spans all the departments within the hospital and reviews the cases involving patient deaths, unexpected adverse outcomes, incident reports, quality measure fallouts and random physician quality reviews. Cases designated a Code R were identified and the following information was collected using a standardized form: peer review level assigned, area of deficiency, resident post-graduate year, originating department, month, and time of day. Care issues were characterized into the five core competencies of patient care, medical knowledge, professionalism, communication/interpersonal skills and systems-based practice. The chi-square and Fisher's exact tests were used to make comparisons and an a priori statistical level of significance of p value ≤ 0.01 was used to adjust for multiple comparisons.

RESULTS: Between 2008 and 2011, 8052 individual cases were peer reviewed by the medical staff and 258 (or 3.2 %) had "Code R" assigned. Of the total charts initially identified, nine cases were determined to not be resident related, nine charts were unavailable and two cases had incorrect medical record numbers. Two hundred thirty-eight charts qualified for final data analysis. The peer reviewed designations and prevalence in each category were Level 1 (Meets standard)- 13 (5.5 %), Level 2 (Meets standard - opportunity for improvement) -196 (82.4 %), Level 3 (Deviation from standard) -26 (10.9 %), and Level 4 (Unacceptable care) -3 (1.3 %). Compared with the non-Code R, or attending physician cases, there were significantly more errors in all the competencies (5.5 % vs. 89.3 % Level 1 assignments for resident vs. attending physicians). In the Code R cases, 60 % (143/238) of the charts had documentation issues. One-third (79/238) of the charts had deficiencies in patient care issues, which include clinical judgment, decision-making and lack of follow-up. The next most common errors were in the competencies of Systems-based Practice and Interpersonal Communication, 9.2 % and 8.0 % respectively. We did not find any significant differences in resident errors by time of day or calendar year. However, interns (PGY-1) were more prone to errors than senior residents (PGY ≥ 2) ($p=0.002$).

CONCLUSIONS: The introduction of "Code R" helped identify cases in which resident involvement potentially impacted patient care and safety. Our analysis of Code R cases suggest specific areas for focused resident supervision and education are needed in the areas of documentation and patient care. This simple peer review process can be readily adopted by other institutions to help improve resident education, facilitate attending supervision, and potentially improve patient safety. Use of this instrument can be used to track the individual resident and attending performance that has not been previously described.

"HAVE YOU THOUGHT ABOUT SENDING THAT AS AN ECONSULT?": PRIMARY CARE PROVIDERS' EXPERIENCES WITH ELECTRONIC CONSULTATIONS AT AN ACADEMIC MEDICAL CENTER Sara Ackerman¹; Gina Intinarelli⁴; Nathaniel Gleason²; Michael Wang³; Sereina Catscheign²; Delthia McKinney⁴; Ralph Gonzales². ¹University of California, San Francisco, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA; ³University of California, San Francisco, San Francisco, CA; ⁴University of California, San Francisco, San Francisco, CA. (Tracking ID #1936109)

BACKGROUND: Electronic consultations (eConsults) are a recent innovation enabling primary care clinicians to request advice from specialists, via a shared electronic health record (EHR), for lower-complexity clinical problems that do not require an in-person evaluation of the patient by the specialist. Prior studies suggest that eConsults can improve the time-to-access to specialty care and reduce specialty care office visit utilization. Using in-depth interviews, we sought to elucidate primary care providers' (PCPs) experiences with a recently adopted eConsult program at an academic medical center.

METHODS: We recruited a purposive sample of PCPs from an academic medical center with a recently implemented EHR-based program in which specialists and PCPs receive reimbursement for completed eConsults. Semi-structured interviews were conducted to explore the benefits and limitations of eConsults and their impact on clinical work - including information transfer and clinician-patient and PCP-specialist interactions. Interviews were audiotaped, professionally transcribed, and checked for accuracy. Each interview transcript was reviewed by at least two authors in addition to the interviewer. The constant comparative method was used by the team to collaboratively and iteratively develop themes related to the study objectives.

RESULTS: Nine interviews have been completed to date, with participants representing a range of primary care professions and levels of experience, including faculty physicians, medical residents and nurse practitioners. A total of 20 interviews will be completed by March 2014. We identified three key thematic domains related to eConsult benefits, limitations, and influence on clinical work. 1) **Access to expert advice:** Most participants reported that eConsults were preferable to the use of informal, or "curbside", consultations because they offer timely and standardized access to specialist advice without requiring PCPs to call on social networks or ask

for favors, and because the consultation is stored in the electronic medical record and is conveniently linked to information about related tests and treatments. As one PCP explained, "I like that it is more formal and that it gets into the patient's chart and it is recorded and I can refer to it later." Nonetheless, the occasional use of curbside consultations persisted even among PCPs who routinely use eConsults, and was not seen as incompatible with eConsult use. The perception that an eConsult renders the specialist part of a patient's care team, while simultaneously obviating the need for an office visit, was also reported as a source of increased patient and PCP satisfaction. 2)

Providing better care: The use of eConsults was associated with increased clarity about specialists' and PCPs' roles, more transparent and efficient care coordination procedures, and PCPs' enhanced participation in determining a patient's follow-up plan. "I just feel like I'm providing better primary care", said one PCP. Some participants reported that patient management using an eConsult is more time-consuming, and entails greater responsibility on the part of the PCP, than a traditional consultation, but most felt that this was an acceptable tradeoff for the satisfying learning opportunities and increased sense of mastery accompanying the incorporation of eConsults in their workflow. 3) **Uneven adoption patterns:** A minority of participants was less enthusiastic about eConsults and the frequency of use varied widely among individual providers. Some PCPs described a reluctance to initiate an eConsult because of difficulty with technical aspects of the program, frustration with slower-than-promised responses from consultants, or concern about how and when to communicate with patients regarding a consultant's recommendations. Others reported "pushback" from patients who wanted in-person advice from a specialist. Most participants reported weighing both clinical and non-clinical factors when deciding when to request an eConsult. "That is why I choose the right patients...", said a PCP about the need to balance clinical appropriateness and patient preference when deciding between an eConsult and a conventional referral.

CONCLUSIONS: Our results suggest that eConsults present an effective strategy for improving PCPs' ability to obtain specialist expertise, and that they increase PCPs' engagement and satisfaction with their clinical work. However, eConsults do not uniformly replace informal "curbside" consultation practices, and decisions about their use are influenced by non-clinical factors such as convenience, usability of the electronic interface, and patient preference. eConsult program designers should elicit continual feedback from providers in order to increase the ease of use and appeal of this mode of consultation.

"IN THE MILITARY, YOUR BODY AND YOUR LIFE AREN'T YOUR OWN:" UNIQUE FACTORS INFLUENCING HEALTH BEHAVIOR CHANGE IN OVERWEIGHT AND OBESE VETERANS Melanie Jay^{1,3}; Katrina F. Mateo^{1,2}; Molly Horne^{2,1}; Allison Squires^{4,2}; Adina Kalet²; Scott Sherman^{1,3}. ¹VA NY Harbor Healthcare System, New York, NY; ²NYU School of Medicine, New York, NY; ³NYU School of Medicine, New York, NY; ⁴NYU College of Nursing, New York, NY. (Tracking ID #1920967)

BACKGROUND: Obesity affects 36 % of the Veteran population. The Veterans Affairs (VA) Healthcare System offers an intensive weight management program called MOVE!, but only approximately 10 % of eligible patients attend even one session. Since veterans see their PCPs 3.6 times per year, developing primary care-based weight management interventions may improve MOVE! attendance. To inform intervention development, we conducted a single-center qualitative study to explore unique VA patient 1) attitudes, barriers, and facilitators to healthy behavior change; 2) uses and understandings of goal-setting; and 3) weight management-related experiences with health care providers, technology, and MOVE!.

METHODS: We sent recruitment letters to overweight and obese patients at the New York Harbor VA. Eligibility criteria included Veterans aged 18–75, having a BMI ≥ 30 or ≥ 25 with at least one co-morbidity, and self-reported ability to read and participate in focus groups. We organized patients into focus groups of 6–11 participants, grouped by gender and MOVE! attendance. The interview guide was informed by the Theory of Planned Behavior (TPB). Sessions were audio-recorded, contextually supplemented with field notes, and transcribed by a professional company. Initial codes were determined based on session recollection and field notes. Using an iterative coding approach, two coders separately reviewed segmented transcripts, modified the codebook as new codes emerged, and met to negotiate codes. We utilized NVivo software to assist with coding and subsequent thematic analysis.

RESULTS: We screened 161 patients for eligibility, 77 were scheduled to attend, and 54 attended one of six focus groups (two female and four male). Participants were predominantly male (63 %), African-American (46 %) or White/Caucasian (32 %), college-educated or higher (74 %), and reported having attended MOVE! (61 %). We found that although we attempted to stratify focus groups by MOVE! attendance, the VA electronic health record did not accurately capture this information, and some

study participants were confused or unaware of their attendance. Thematic analyses revealed how military service informed participants' attitudes, social norms, and perceived behavioral control with regards to weight management. Participants described how the structured environment and strict standards of the military motivated them to maintain weight control while enlisted, but that lack of autonomy was a barrier to learning how to manage their health when they left service. The military also influenced their perceived need for more personalized and tailored health counseling. Physical activity was largely considered the predominant method to lose weight, and participants felt the MOVE! program lacked a physical activity-related component. While participants acknowledged the potential usefulness of technology to help identify and achieve weight management goals, they expressed the need to have a knowledgeable person (i.e. health coach, PCP, dietitian, etc.) provide guidance and support.

CONCLUSIONS: This study revealed how military service may influence veterans' intentions to lose weight and their weight management-related experiences. This will guide the development of a computer-assisted intervention to treat obesity within primary care and improve access and quality of weight management services. The implications from this study may be limited as it was conducted at a single site within a specific and a mostly self-selected patient population.

"NONE OF THEM APPLY TO ME:" A USABILITY STUDY OF THE VA'S MOVE!23 ONLINE WEIGHT MANAGEMENT SOFTWARE IN LATINA WOMEN Hector R. Perez⁴; Michael W. Nick⁵; Katrina F. Mateo^{1,2}; Scott Sherman^{1,3}; Adina Kalem²; Melanie Jay^{1,3}. ¹VA NY Harbor Healthcare System, New York, NY; ²NYU School of Medicine, New York, NY; ³NYU School of Medicine, New York, NY; ⁴NYU School of Medicine, New York, NY; ⁵NYU School of Medicine, New York, NY. (*Tracking ID #1920971*)

BACKGROUND: The obesity epidemic disproportionately affects Latina women, but there are few interventions in this population. The MOVE!23 software program is a publicly available, English-only, online questionnaire used by the Veteran's Affairs (VA) Administration to facilitate weight management. It evaluates patients' current behaviors and stage of change and provides computer-generated, individualized advice. Completion of MOVE!23 during an intensive weight management program is associated with greater 6-month weight loss outcomes. Thus, adapting this tool for use in Latina women may be beneficial. However, the MOVE!23 is not specifically tailored for use in non-VA populations and its usability in this population is uncertain. The International Organization for Standardization (ISO) defines usability as "the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use." In order to determine the utility of tailoring the MOVE!23 for Latina women and translating it into Spanish, we conducted usability testing of this software.

METHODS: We recruited English-speaking, adult Latina women. A researcher observed each participant individually as they used the MOVE!23. Participants were asked to verbalize their thoughts and reactions as part of a "Think-Aloud" protocol. A semi-structured interview followed that elicited reflections on this experience and how it might influence lifestyle behavior change. We utilized ScreenFlow (Version 4.0.3) to capture on-screen interactions, and each session was digitally recorded and professionally transcribed. A coding guide was derived from the ISO definition of usability and focused on positive and negative interactions between four domains (Tool, Task, User, Context). Two researchers reviewed and coded the transcripts independently using the guide and secondary codes were derived inductively. The researchers met to review the codes and resolve discrepancies. NVivo software was used to facilitate data analysis.

RESULTS: Six female Latina participants completed the study (mean age 39, SD=17); all had lived in the US for more than 20 years. Analysis indicated general satisfaction with tool navigation and the content, sequencing and segmentation of materials. Participants wanted individualized patient handouts to be more accessible and easily available on paper and suggested that images and icons might enhance visual appeal. Significant tool-user interactions included problems with navigation, difficulty understanding questions and answer choices, and sensitivity to the personal nature of the topics. User-context interactions included lack of experience with technology and requests for more support during completion of the questionnaire. In addition, subjects described personal experiences or beliefs while interacting with the materials. The extent to which questions or advice approximated their own experiences influenced the ease with which they were understood.

CONCLUSIONS: This study supports the utility of translating and tailoring the MOVE!23 for use in Latina women and identified several areas for improvement. Findings suggest that task execution may be enhanced when users are able to compare and reconcile the online materials with personal experiences and beliefs,

highlighting the need to take these into consideration when tailoring software. Further research will aim to tailor and pilot the MOVE!23 software in populations of Latina women.

"SOMEDAY IT WILL BE THE NORM": PHYSICIAN PERCEPTIONS OF THE CLINICAL UTILITY OF WHOLE GENOME SEQUENCING Jason L. Vassy^{1,2}; Kurt D. Christensen²; Melody J. Slashinski³; Denise Lautenbach²; Jill Oliver Robinson³; Jennifer A. Blumenthal-Barby³; Lindsay Feuerman³; Robert C. Green²; Amy L. McGuire³. ¹VA Boston Healthcare System, Boston, MA; ²Brigham and Women's Hospital, Boston, MA; ³Baylor College of Medicine, Houston, TX. (*Tracking ID #1934488*)

BACKGROUND: There is excitement that medicine is entering a genomic era, in which knowledge of one's genetic makeup can guide medical decision-making. Whole genome sequencing (WGS) can identify 3–5 million genetic variants for an individual. However, the clinical significance of most of these variants is currently unknown, and the specific clinical contexts in which WGS might add value to current standards of care have not been identified. The uptake of WGS into medical practice will largely depend on whether and how physicians perceive it to improve patient care.

METHODS: We have enrolled primary care physicians (PCPs) and cardiologists to participate with their patients in the MedSeq Project: a randomized trial of WGS in the clinical care of healthy adult primary care patients and cardiomyopathy patients. We used mixed methods to describe the clinical utility that physicians perceive WGS to have. In a baseline survey on enrollment, we asked physicians to rate on a scale of 1–10 ("Not at all useful" to "Extremely useful") how useful they thought WGS would be for "managing [their] patients' health" at two times: now and in the future. We categorized responses as not useful (1–5) or useful (6–10) for analyses. We then conducted in-depth semi-structured interviews to explore whether and in what circumstances physicians might perceive WGS to have clinical utility. Transcribed interviews were consensus-coded with thematic content analysis to identify emergent themes.

RESULTS: Of 17 physicians (mean age 52 years), nine were women, and five were of non-white race. Nine were PCPs, and 11 reported no genetics training "beyond the typical medical school curriculum." Only 4 (24 %) said that WGS had utility now, but 15 (88 %) predicted it would have future utility for their patients' care. We identified three major themes influencing physician perceptions of utility. 1) Inevitability: Physicians expected WGS to be widely integrated into medical practice in the near future. When asked his opinion about the routine use of WGS in clinical care, one responded, "That's like saying, 'What do I think about getting cholesterol tests on people?' I mean, it's a reality, and I think it's going to happen." 2) Uncertainty: Physicians perceived WGS results to have too little analytic and clinical validity at present to be useful for patient care. One commented, "It's like doing a CT scan and finding a nodule and not knowing what it means. And the next thing you know, you have a biopsy, and then you have a complication from the biopsy." 3) Contexts of utility: In particular, physicians anticipated that WGS may 1 day be useful for nudging patient behavior change, tailoring drug therapy (pharmacogenomics), and efficiently targeting preventive health maintenance. One said, "If it turns out that we don't have to do colonoscopies every 10 years on 100 % of the people, maybe that will save a lot of money. If we know who we really should be doing PSA's or mammograms on, instead of doing them on everybody, we can save a lot of money, stop creating a lot of harm and disability." Physicians often used analogies to current medical testing to describe their perceptions of WGS.

CONCLUSIONS: Physicians are skeptical about the current clinical utility of WGS for general patient care but anticipate a near future when the clinical integration of WGS will be widespread. Evidence that WGS improves health outcomes will likely be necessary to persuade physicians of its utility in patient care.

"WE TORTURE THEM BEFORE THEY DIE, EVEN THOUGH WE KNOW THAT THEY ARE GOING TO DIE:" THE INFLUENCE OF HOSPITAL POLICIES AND CULTURE ON ETHICAL DNR DECISION MAKING IN THE US AND UK Elizabeth Dzeng^{1,2}; Michael P. Kelly²; Sydney M. Dy¹; Thomas J. Smith¹; Martin Roland²; Stephen Barclay²; David M. Levine¹. ¹Johns Hopkins School of Medicine, Baltimore, MD; ²University of Cambridge, Cambridge, United Kingdom. (*Tracking ID #1939234*)

BACKGROUND: Physicians face ethical challenges when there are conflicts between autonomy and beneficence, which is defined as acting in the best interest

of the patient. Shared decision-making, where the patient and doctor form a partnership to decide on treatment plan, has emerged as a model on the spectrum in between medical paternalism and patient autonomy. In the United States, there are significant variations in hospital policies regarding Do Not Resuscitate (DNR) decision-making. In the United Kingdom, it is standard practice for doctors to make unilateral decisions to institute a DNR order in situations where survival is unlikely. The aim of this study is to explore how doctors in the US and UK balance autonomy and beneficence in decisions regarding DNR status at the end of life and how their ethical values and clinical approach are shaped by their institution's culture and legal frameworks.

METHODS: Semi-structured in-depth interviews were conducted with 58 internal medicine doctors across four sites (New York, Baltimore, Seattle and Cambridge, England), who were routinely involved in DNR conversations with end of life patients. Participants were purposively sampled by stage of training and medical subspecialty to provide a wide range of perspectives and contribute to understanding emerging patterns and themes. Interviews lasted on average 60 min and were audiotaped and transcribed. Transcripts were analyzed and double coded using thematic analysis with an interpretive approach.

RESULTS: 13–16 doctors participated at each site. Approximately equal numbers of senior faculty, junior faculty, fellows and residents were interviewed. Experienced doctors at all sites generally felt comfortable engaging in shared decision-making and when clinically appropriate, making more paternalistic recommendations against resuscitation. However, there was greater variation amongst residents and fellows that was site specific. At each hospital, there appeared to be a dominant mode of decision-making that impacted trainees' perspectives on DNR decision-making. Although hospital policies primarily dictate whether patient preferences should be honored, trainees at hospitals with policies that prioritize patient autonomy often interpreted them to mean that they should not provide clinical recommendations. They felt compelled to offer choice even if the chance of successful resuscitation was negligible. In contrast, trainees at hospitals that had policies that encouraged paternalism or shared decision-making, which included the hospital in the UK and one in the US, felt more comfortable expressing clinical judgment against resuscitation when appropriate. Trainees at hospitals that prioritized autonomy more frequently perceived conflict between honoring autonomy and acting with beneficence and recalled more conflicts with patients regarding preferred decision.

CONCLUSIONS: Institutional norms and policies influence how doctors develop their professional attitudes and practices regarding DNR decision-making. Doctors at the American hospital that encouraged shared decision-making, had attitudes and beliefs about DNR decision-making that were more similar to British doctors than doctors at the other American sites. Hospitals characterized by higher levels of shared decision-making and paternalism provided an environment where trainees felt more comfortable withholding resuscitation when success was unlikely and in doing so, experienced fewer patient conflicts.

"WHAT DOES A GOOD LIFESTYLE MEAN TO YOU?" A QUALITATIVE ANALYSIS OF FIRST YEAR MEDICAL STUDENTS' VIEWS Kimberly Clinite¹; Alex Garnett¹; Shalini Reddy¹; Kent DeZee²; Stephanie Kazantsev¹; Steven Durning²; Jennifer R. Kogan³. ¹University of Chicago, Pritzker School of Medicine, Chicago, IL; ²Uniformed Services University, Bethesda, MD; ³Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA. (Tracking ID #1938451)

BACKGROUND: Medical students consider a specialty's lifestyle when selecting a career; meeting the physician workforce shortage requires an understanding of how students define a "good" lifestyle. Understanding the lifestyle expectations of entering students may help medical educators guide students towards careers that will fulfill their ambitions and serve the health needs of our society. The purpose of this study was to determine how first year medical students define a good lifestyle.

METHODS: First year medical students at 11 schools were surveyed at matriculation in 2012. The survey included the open-ended question, "When someone says 'That specialty has a good lifestyle,' what does that mean to you?" Two investigators performed a directed content analysis of responses. Descriptive statistics of the themes were calculated.

RESULTS: 60 % (1020/1704) of students completed the survey; 934 answered the open-ended question. Responses encompassed four major themes: schedule control (66 % of students), off-time (54.5 % of students), financial aspects (35 % of students), and work-life (21 % of students). Schedule control was described with multiple

subthemes (reasonable hours, flexible hours, predictable hours, and limited call). Nine student responses were categorized as disparaging.

CONCLUSIONS: This study has helped establish how matriculating medical students define lifestyle, a known factor in career selection. Matriculating medical students' definition of lifestyle is largely defined by schedule control, though students' concept of schedule control varies. Salary associated with a good lifestyle ranged from \$175,000–\$400,000. Understanding early perceptions of career decision-making may provide a context for medical educators to begin conversations with students about career choice. Additionally, specialties experiencing physician shortages should consider how their specialty will evolve to meet the needs of society while addressing the concerns of trainees. Policies that hope to successfully address the medical workforce shortages must account for students' desire to have control of their work schedule.

"WHEN YOU ARE OLD, HAVE CANCER AND A STORM IS APPROACHING" -THE EFFECTS OF HURRICANE SANDY ON CANCER PATIENTS AND PROPOSALS ON POTENTIAL INTERVENTIONS Misako Nagasaki¹; Hassan Alsabbak¹; Zaid Aljuboori²; Koji Sasaki³; Alfred Burger¹; Benjamin Levy¹. ¹Beth Israel Medical Center, New York, NY; ²Bronx Lebanon Hospital, New York, NY; ³MD Anderson Cancer Center, Houston, TX. (Tracking ID #1939110)

BACKGROUND: The estimated loss to the nation's economy from Hurricane Sandy has climbed to as much as \$50 billion, making it one of the nation's most costly disasters. While data on the economic impact of natural disasters are often reported in a timely manner, very little data exists on the impact of natural disasters to health care, especially in cancer care.

METHODS: A retrospective chart review was performed to examine the impact of Hurricane Sandy and the subsequent blackout in southern Manhattan on emergency room (ER) visits of patients with a diagnosis of cancer. The records of cancer patients who had visited ER during the week of Hurricane Sandy (10/29/2012 to 11/4/2012) were reviewed. For control, ER visits of cancer patients of the same dates 1 year prior (10/29/2011 to 11/4/2011) were reviewed and compared. All data were extracted from the ER and/or inpatient electronic medical records. Collected data included age group, sex, cancer type, chief complaint, ER diagnosis and admission status. The diagnosis of cancer was extracted from the "History of Present Illness" or "Past Medical History" and included solid as well as hematologic malignancies. For patients who were admitted, additional data including metastatic disease, comorbidities, length of stay and mortality were extracted.

RESULTS: During the week of Sandy, 144 ER visits of cancer patients were identified. One hundred eighteen were identified the prior year. In patients over age 70, 84 visits were observed during Sandy, while only 41 visited the previous year (p value: 0.000143). The chief complaint of "shortness of breath (SOB) or asthma" was significant, with 21 ER visits in 2012 and only eight in 2011 (p value: 0.045). Out of the 21 visits of SOB, 10 required continuation of their current therapy (8 requested home oxygen therapy and two requested dialysis), while these requests were unobserved the prior year. During the Sandy week, 77 ER visits resulted in admission, while 64 were admitted the year prior (p value: 0.902). Out of 77, seven expired and from 64, four expired (p value: 0.759). The ER admitting diagnoses of the seven who expired during Sandy included a septic patient with fungating head and neck cancer, a brain cancer patient with respiratory failure, a lung cancer patient with pleural effusion, a sarcoma patient with pneumonia, an ovarian cancer patient with anemia, a melanoma patient with acute coronary syndrome and a lung cancer patient with SOB requesting home oxygen therapy. Corresponding data from the year prior included a lung cancer patient with pancytopenia, a CLL patient with pneumonia, a septic patient with breast cancer and a lung cancer patient with suicidal ideation.

CONCLUSIONS: Although there were no significant increase in the total ER visits of cancer patients during Sandy, there were significantly more ER visits during Sandy in cancer patients over age 70, suggesting increased vulnerability to this cohort. To our knowledge, this is one of the first few studies to evaluate cancer care related to natural disasters. In retrospect, the admission and death of a lung cancer patient with SOB requesting continuation of home oxygen therapy may have been the one potentially preventable. Cancer patients requiring additional medical assistance such as home oxygen therapy and dialysis may benefit from a natural disaster back-up plan. House calls, early and prioritized evacuation of these patient groups may be some options to minimize the effects of an approaching natural disaster.

Top 10 Chief Complaints

Chief Complaints	2011	2012	p value
SOB or asthma	8	21	0.049
Chest pain or discomfort	7	11	0.6

Pain in extremities	9	7	0.43
Requesting dialysis	0	6	0.034
Nausea and vomiting	3	6	0.51
Intoxication	4	6	1

30 DAY READMISSION RATE FOR PATIENTS DISCHARGED WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD): ANALYSIS OF 1,858,618 ADMISSIONS. WHICH PATIENTS ARE MOST AT RISK? Devin B. Malik; Sourabh Aggarwal. Western Michigan University School of Medicine, Kalamazoo, MI. (Tracking ID #1939043)

BACKGROUND: COPD is a major cause of morbidity and is associated with a high 30-day re-admission rate (RR) and economic burden on health care. This study was done to determine demographic parameters associated with high 30-day RR secondary to COPD.

METHODS: Nationwide Inpatient Sample data was used to extract data of patients discharged with DM with complications for years 2009–2011 using clinical classification software (CCS). NIS represents 20 % of all hospital data in US. All the patients who were discharged with primary diagnosis of COPD and readmitted within 30 days were identified and categorized based on admitting diagnosis. Patients were classified as readmissions secondary to COPD as a primary cause, readmissions with COPD as a secondary cause and non-COPD associated readmissions. Statistical analysis was done using SPSS.

RESULTS: We identified a total of 1,858,618 admissions for COPD nationwide during the study period with total 30-day RR of 21.06 % and RR of 7.22 % secondary to COPD as a primary cause (Table 1). Age group (45–64), males, patients under Medicaid, patients in low median income for zip code and in metropolitan areas had higher 30-day re-admissions secondary to COPD as a primary cause ($P < 0.001$). Young patients (18–44 years of age), females, patients covered under Medicaid and living in Metropolitan areas had higher 30-day RR secondary to non-COPD related causes.

CONCLUSIONS: Strategies to reduce 30-day readmissions secondary to COPD should be focused on more susceptible population including males, aged 45–64 years old, under Medicaid, having low median income for zip code and staying in metropolitan areas.

A CLUSTER RANDOMIZED CONTROLLED TRIAL OF INTERVENTIONS TO IMPROVE WORK CONDITIONS AND CLINICIAN STRESS: RESULTS FROM THE HEALTHY WORK PLACE (HWP) STUDY Mark Linzer¹; Sara Poplau²; Ellie Grossman³; Steven H. Yale⁴; Anita B. Varkey⁵; Eric Williams⁶; Lanis Hicks⁷; Roger Brown⁸; Jill Wallock⁵; Diane Kohnhorst⁴; Michael Barbouche⁹. ¹Hennepin County Medical Center, Minneapolis, MN; ²Hennepin County Medical Center, Minneapolis, MN; ³New York University Medical Center, New York, NY; ⁴Marshfield Clinic, Marshfield, WI; ⁵Loyola University Medical Center, Chicago, IL; ⁶University of Alabama, Tuscaloosa, AL; ⁷University of Missouri, Columbia, MO; ⁸University of Wisconsin, Madison, WI; ⁹Forward Health Group, Inc., Madison, WI. (Tracking ID #1927618)

BACKGROUND: Work conditions in primary care are associated with stress, burnout, intent to leave the practice and quality of care. Time pressured office visits, lack of control of the workplace, a chaotic work pace, and lack of values alignment between clinicians and leaders contribute to stress and burnout. To determine the best ways to organize clinical practice, we measured the effects of work condition interventions on clinician and patient outcomes. Our goal was to assess if a “healthy workplace” could decrease clinician stress and improve care quality. This abstract reports on clinician outcomes.

METHODS: We performed a cluster randomized controlled trial in 34 rural and urban clinics in the upper Midwest and New York City. Primary care clinicians (general internists, family physicians, nurse practitioners and physician assistants) were studied. Seventeen clinics were randomized to participate in quality improve-

ment interventions (QIIs) to improve worklife. Time pressure, work control, pace of work (chaos) and values alignment with leaders were measured at baseline and approximately 1 year later, along with clinician stress, burnout, satisfaction and intent to leave the practice in 2 years. The 17 clinics randomized to the intervention arm received their baseline data in an Office and Work Life (OWL) summary measure. QIIs were chosen by clinics based upon baseline OWL data, and focused predominantly in three areas: 1) improved communication, 2) changes in workflow and 3) clinical QI projects (e.g., a new prescription-refill telephone line, or a medication reconciliation project). Two level multilevel regression analysis was performed to assess the impact on clinician outcomes of being in the intervention arm. When these analyses did not disclose an overall intervention effect, we then explored whether clinicians who showed improvement in burnout, satisfaction or intent to leave the practice were more likely to be found in intervention clinics. Multivariate modeling determined which types of interventions were associated with improvement in these clinician outcomes.

RESULTS: Within 34 clinics, 166 clinicians were initially studied, and 139 subjects completed the study. Data were analyzable from 32 clinics and 135 clinicians. Burnout was present at baseline in 41 % of clinicians in intervention clinics and in 33 % of controls. While there was no overall effect of all interventions considered together, there were more clinicians with improvement in burnout in intervention vs. control clinics (21.8 % versus 7.1 %, Odds Ratio (OR) of burnout improvement 4.0, $p=0.014$). Burnout was almost six times more likely to improve within clinics performing workflow interventions than in control sites (OR 5.9, $p=0.015$), and was also more likely to improve in clinics performing clinical QI projects (OR 4.8; $p=0.021$). Clinician satisfaction improved more often in the 10 clinics with interventions in the areas of communication and workflow than in control sites (OR 3.1; $p=0.042$). **CONCLUSIONS:** While these results should be confirmed in future studies, they suggest that organizations can address high rates of burnout by 1) measuring clinician outcomes (satisfaction, stress and burnout), 2) providing feedback on these outcomes to clinicians, clinic managers and staff, and 3) intervening by improving communication and workflow and initiating clinical QI projects.

A COMMUNITY PARTNERED APPROACH TO ENGAGE DIVERSE COMMUNITIES IN STROKE DISPARITIES RESEARCH Nazleen Bharmal¹; Aziza L. Wright^{3,2}; Stefanie D. Vassar¹; Felicia U. Jones³; Loretta Jones^{3,2}; Rebekah Wells⁴; Jason Cienega²; Arleen Brown¹. ¹University of California, Los Angeles, Los Angeles, CA; ²Charles R. Drew University of Medicine & Science, Los Angeles, CA; ³Healthy African American Families II, Los Angeles, CA; ⁴University of North Carolina, Greensboro, NC. (Tracking ID #1929958)

BACKGROUND: Racial/ethnic minorities have a higher burden of stroke and worse post-stroke outcomes. Contributors to this disparity include lower awareness of stroke signs and treatment, differences in access to care, mistrust in the healthcare system, and low participation in stroke clinical research studies. Despite emerging evidence that community input into interventions may enhance feasibility and sustainability, few stroke studies have incorporated the community perspective. The Los Angeles Stroke Prevention & Intervention Research Program to Reduce Health Disparities (LA SPIRP) is a center to reduce stroke disparities. The Community Engagement Core of LA SPIRP consists of community and academic co-leaders that review projects and work with investigators to understand community research priorities. To enhance public engagement in stroke research, our community-academic collaborative hosted a one-day symposium in South Los Angeles. The objectives of the symposium were to increase awareness of stroke, share information about and receive feedback on the LA SPIRP research projects, and promote collaboration between researchers and community partners to address stroke disparities.

METHODS: We used a community-partnered participatory research process to conceptualize the symposium. The symposium started with talks that provided information on stroke risk factors, stroke disparities, and the impact of stroke from the perspective of patients and caregivers. Simultaneous translation was available for monolingual Spanish speakers, and printed materials were available in English, Spanish, Korean, and Mandarin. We surveyed participants about stroke knowledge, stroke disparities, and trust in medical researchers. In the afternoon, attendees participated in six facilitated, small group breakout sessions (one conducted in Spanish) that addressed two questions: 1) What can we do as a community to prevent stroke?, and 2) How can we recruit more diverse populations in stroke research studies? Breakout session notes were analyzed using qualitative data analysis: content analysis used to code notes from group and pile-sorting by community and academic attendees to identify themes.

RESULTS: The symposium was attended by 236 community residents; staff from local clinical, social service, and faith-based organizations; and researchers. The

survey response rate was 54 %. Over 90 % of the attendees were African American, Latino, or Asian; 40 % had hypertension. The majority of respondents had limited prior knowledge of stroke, and most had learned about stroke from family members, friends, or media. The average increase in knowledge about stroke pre- and post-didactic sessions was 15 %. On average, 21 % of respondents did not trust medical researchers to provide full explanations of research studies or protect participants from harm. Community recommendations for community-based strategies to prevent stroke focused on types of educational efforts ($n=128$ quotes), educational content and cultural considerations (79), venues to share information (65), healthy eating efforts (50), partnerships with trusted stakeholders and institutions (34), types of audiences to receive stroke awareness information (30), physical activity efforts (26), and blood pressure screening (14). Community recommendations to enhance minority recruitment into clinical research studies included types of outreach methods (116), communication strategies (72) and partnerships with trusted stakeholders (51) to gain trust, types of incentives for participation (48), and considerations about the relevance and location of the research study for minorities (11).

CONCLUSIONS: Community-academic partnered events are effective ways to obtain community input into stroke research and may build trust and foster collaborations with community members for stroke research. Recommendations from the community stroke symposium will be used to frame future annual symposia, inform current LA SPIRP research, and develop smaller, culturally targeted stroke disparities programs in African-American, Latino, Korean, and Chinese-American communities in Los Angeles.

Recommendations from Breakout Sessions

Community strategies to address stroke disparities	Community strategies to increase diversity in stroke research studies
• Culturally sensitive advertising on risk factor reduction	• Investigators should partner with community organizations to increase trust in research
• Community participation in media campaigns	• Have trusted, community-based medical and non-medical personnel recruit for studies
• Use mobile vans to provide access to information and medical treatment	• Use stories to appeal to community members
• Educate primary and secondary students about stroke risk factors	• Research that benefits the community
• Make healthy food affordable (e.g., community gardens, local farmers' markets)	• Provide non-monetary incentives (e.g., blood pressure monitors)
• Recognize the family's role in prevention	• Research takes place in the community

A COMPARISON OF ACTIVE ADVERSE EVENT SURVEILLANCE SYSTEMS WORLDWIDE Jodi B. Segal^{1,2}; Yulin Huang¹; Jinhee Moon¹. ¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #1930394)

BACKGROUND: Typically, fewer than 5,000 people have been exposed to a drug before marketing, so adverse drug events (ADEs) at low frequency will not have been observed. Drug regulatory agencies and industry are vigorously developing active surveillance systems for drugs, vaccines, and medical devices in order to quickly identify therapies causing harm to exposed patients. We conducted an environmental scan in order to describe the status of active surveillance systems for the detection of ADEs, worldwide.

METHODS: We developed a working definition of active surveillance systems. The key components of the systems that we sought to capture were: Structure—what is the structure, partnership relationships, and funding of existing active surveillance systems? Data—what are the data used in existing surveillance systems, what patient populations are included, and what is the content of these data? Function—what are examples of adverse drug events that have been identified with the active surveillance systems? Paired researchers reviewed published literature, as well as online sources, to identify existing systems. Data was extracted into tables designed to capture the key components of the active surveillance systems. We reviewed and synthesized the information across systems to identify common, and presumably, essential features of active surveillance systems.

RESULTS: We identified 12 active surveillance systems meeting our criteria, meaning that they were designed for post-marketing surveillance of pharmaceutical products (including vaccines), had a goal of generating post-marketing drug safety information, do not require personnel to initiate safety reports (describing individual

cases), use real-world data which are generated from routine practice, and involve data from more than a single institution. Three systems are U.S. based - the FDA Sentinel Initiative, the Federal Partners Collaboration, and the Vaccine Safety Datalink; two are Canadian systems—The Canadian Network for Observational Drug Effect Studies (CNODES) and the Vaccine and Immunization Surveillance in Ontario (VISION); and two are European—the EU-Adverse Drug Reaction (ADR) Alliance and the Vaccine Adverse Event Surveillance and Communication (VAESCO). Additionally, there is a Japanese surveillance system called the Medical Information for Risk Assessment Initiative (MIHARI), a trans-Asian system called the Asian Pharmacoepidemiology Network (AsPEN), and one in Shanghai called the Shanghai Drug Monitoring and Evaluative System (SDMES). Two additional systems in the U.K. met our criteria: the Tayside Medicines Monitoring Unit (MEMO) and the Drug Safety Research Unit (DSRU), an independent academic unit that uses diverse European data for pharmacovigilance. The surveillance systems all use administrative claims or electronic medical records for data; some conduct pharmacovigilance explicitly on behalf of a regulatory agency, while others function more independently. **CONCLUSIONS:** Active surveillance systems are rare. North America and Europe have the most developed systems and most coverage of the population; although some Asian countries are making good advances. There is no coverage of the patients exposed to medications in India, the Eastern European countries, or the South American and African continents. With the ever increasing availability of electronic data, active ADE surveillance should be increasing feasible. This should translate to more rapid signal detection, timely validation, and then steps to assure that drugs and vaccines are used safely.

A DESCRIPTION OF NEEDS FOR CARE COORDINATION AT A COMMUNITY-BASED GENERAL HOSPITAL IN JAPAN'S SUPER-AGED SOCIETY Yukio Tsugihashi. ¹Tenri Hospital, Tenri, Japan; ²Tenri Hospital, Tenri, Japan. (Tracking ID #1920518)

BACKGROUND: Japan's population is aging rapidly because of long life expectancy and a low birth rate. In 2025, it is estimated that the percentage of aged population will increase to 25 %. Furthermore, the standout features of the Japanese healthcare system are “universal insurance scheme” and “unrestricted access to any doctor” which add strain to an already overburdened healthcare system. Therefore, a well-designed collaborative system is essential, one that supports the community healthcare and enables functional differentiation and the establishment of referral/transferral networks among a variety of institutions. The purpose of this study is to investigate 1) a medical service area in a community-based general hospital in Japan, 2) the places where the patients were discharged with professional discharge planning and 3) to estimate the future demographic changes in the number of inpatients.

METHODS: Participants: Inpatients discharged from one community-based general hospital in 2012. Setting: Tenri hospital, Tenri city, Nara, Japan (a total of 1001 beds, 26 departments and over 230 medical doctors) Study design: Retrospective cohort study Outcomes: 1) Mapping the medical service area 2) Specifying the places where the participants were discharged from the hospital that provided professional discharge planning 3) Estimating the changes of inpatient numbers and their age groups in 2012, 2025 and 2035. Analysis: First, we described the medical service area by connecting the participants' address code and Geographical Information System (GIS). Second, a focus group interview lead by professional physicians was performed to find out which diseases frequently required professional discharge planning. Then, we evaluated the places where these patients were discharged from the hospital. Lastly, we projected the annual change in the number of inpatients and their respective age groups in the major medical service area for 2025 and 2035 respectively.

RESULTS: A total of 17,196 patients were included in this study. The medical service area was wide and included some cities outside Nara prefecture, the established government-designated administrative medical area (Figure). In addition, we highlighted five disease categories that needed professional discharge planning: cerebral stroke, fracture, cancer, infectious disease and heart failure categories. The results of professional discharge planning showed that the patients' homes were the main place to be discharged to. There were some notable trends found between the places where patients were discharged to and the disease categories (Table). Furthermore, we estimated the change in the number of inpatients living in the top 10 areas to be 12,242 in 2025 (41.2 % of patients being 75 years old or over) and 11,337 in 2035 (42.2 %) compared with 12,088 (30.9 %) in 2012.

CONCLUSIONS: We investigated the medical service area of a community-based hospital in Japan highly reflective of its super-aged society and the needs for care coordination based on the actual practical performance. GIS analysis would help the general hospital to foresee the medical service area more concisely while preparing

for the collaborative healthcare network. Additionally, to prepare for the rapid aging of inpatients, general hospitals should develop a collaborative healthcare system and a system for discharge planning appropriate to the medical service area and disease-specific needs for care coordination.

Table. Places where the participants were discharged from that provided professional discharge planning

A FAILURE TO COMMUNICATE: CHALLENGES AND SOLUTIONS TO CARE COORDINATION BETWEEN HOSPITALISTS AND PRIMARY CARE PROVIDERS AROUND HOSPITALIZATIONS Christine D. Jones¹; Maihan B. Vu²; Christopher O'Donnell³; Mary Anderson¹; Snehal Patel³; Eric A. Coleman⁴; Darren A. DeWalt⁵. ¹University of Colorado, Denver, Aurora, CO; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³Duke University School of Medicine, Durham, NC; ⁴University of Colorado, Denver, Aurora, CO; ⁵University of North Carolina at Chapel Hill, Chapel Hill, NC. (Tracking ID #1933333)

BACKGROUND: Care coordination (e.g., information exchange, direct communication) between hospitalists and primary care providers (PCPs) is critical to successful care transitions from hospital to home, yet such coordination is frequently lacking. We sought to understand care coordination challenges and potential solutions from the perspective of both hospitalists and PCPs in North Carolina.

METHODS: We conducted a qualitative study with eight focus groups (4 hospitalist groups and four primary care groups, 59 total participants). The team recruited practices from diverse settings; six of the groups shared patients between inpatient and outpatient settings. Interview guides were based on the AHRQ Care Coordination Measurement Framework and included questions about care

coordination, information exchange, follow up care, accountability, and medication management. Focus groups were digitally recorded, transcribed verbatim, and analyzed in ATLAS.ti. Two team members independently coded transcripts and resolved differences through discussion. The constant comparison method was used to evaluate differences between hospitalists and PCPs.

RESULTS: Overall, we found that hospitalists and PCPs encounter many similar challenges to care coordination, including: 1) lack of time, 2) difficulty reaching the other provider by telephone, 3) lack of personal relationships with the other provider, 4) lack of clarity about accountability for pending tests and home health orders, and 5) discrepancies between what medications patients are taking and should be taking at home. Specific concerns for hospitalists include: 1) uncertainty about whether PCPs receive information about patient hospitalizations, and 2) difficulty obtaining timely follow up appointments for patients, particularly for after-hours or weekend discharges. Specific concerns for PCPs include: 1) not knowing when their patients are hospitalized, 2) not having records available for post-hospitalization appointments, 3) feeling disrespected by hospitalists when medication changes are made for unclear reasons without their involvement, and 4) difficulty locating important information (e.g., pending tests) in discharge summaries. Hospitalists and PCPs identified common themes to achieving successful care coordination: 1) making extra efforts to coordinate care for "high risk" patient populations (e.g., patients on Warfarin needing INR checks), 2) improving direct telephone access to each other, 3) improved information exchange through sharing EMRs with improved integration of care transitions workflow into EMRs (e.g., enhanced messaging capabilities, scheduling capabilities for follow up), and 4) enhancing personal relationships with clinicians in the other setting.

CONCLUSIONS: Hospitalists and PCPs encounter many similar challenges to care coordination, yet have important experiential differences related to sending and receiving roles for hospital discharges. Challenges that were cited in one setting were often not experienced by clinicians in the other setting. Efforts to improve care coordination between hospitalists and PCPs should aim to understand perspectives of clinicians in each setting. Such solutions include: 1) enhancing direct communication between providers in different settings, 2) clearly defining accountability for tests and home health orders, and 3) building personal relationships between clinicians in each setting.

A HEALTH LITERACY INTERVENTION TO IMPROVE MEDICATION ADHERENCE USING MEDUCATION® TECHNOLOGY Leah L. Zullig; Felicia McCant; S. Dee Melnyk; Susanne Danus; Hayden bOSWORTH. Durham Veterans Affairs Medical Center, Durham, NC. (Tracking ID #1926044)

BACKGROUND: Many Americans are reliant upon medication management for chronic conditions. Medication non-adherence is rampant, leading to increased healthcare cost and worsened health outcomes. Low health literacy is a contributing factor to medication non-adherence. Our objective was to determine whether antihypertensive medication adherence could improve using a Meducation® technology health literacy intervention.

METHODS: We conducted a six-month feasibility study among patients with cardiovascular disease risk factors who received care from hospital-based primary care clinics associated with Durham Veterans Affairs Medical Center (VAMC). To enhance potential benefit and future generalizability, the intervention was integrated into clinics' practice tailored to address needs of high risk, potentially non-adherent patients. All patients received the intervention, which included a personalized Meducation® calendar. We evaluated changes in medication adherence and clinical outcomes at 6 months. Potential participants were initially identified through an electronic health record data pull. To be eligible for study inclusion, patients must have met all of the following criteria: enrolled in one of three primary care clinics affiliated with the Durham VAMC for at least 1 year; had at least one visit to an affiliated primary care provider in the previous 12 months; an outpatient diagnostic code for hypertension (ICD9 401.1, 401.9) diabetes (ICD9 250.x), and/or hypercholesterolemia (ICD9 272.x); prescribed metoprolol tartrate (beta blocker) and have poor medication adherence for the 12 months prior to baseline (medication possession ratio <80 %); and be prescribed more than nine active medications.

RESULTS: There was a 42 % enrollment rate ($n=23$). The sample was predominantly married (57 %), African American (61 %), and male (91 %). Few participants (9 %) completed less than 12 years of school. Forty percent had low health literacy, defined as less than 9th grade reading level. The majority of participants were diagnosed with hypertension (91 %), hyperlipidemia (87 %), or diabetes (61 %). At 3 months self-reported medication

adherence improved. There was a 45 % decrease in participants who agreed or strongly agreed that they sometimes forget their heart medications and 58 % fewer participants reported that they agreed or strongly agreed that they were 'sometimes careless with how they take their medications'. At 6 months, medication possession ratio improved nearly 13 % and there were decreases in patients' average systolic blood pressure (0.5 mmHg), diastolic blood pressure (1.5 mmHg), and body weight (3.6 lb) ($p > 0.05$).

CONCLUSIONS: A health literacy intervention is a feasible mechanism to improve cardiovascular-related medication adherence and outcomes. In this sample, 9 % of participants attained less than a high school level of education, yet 40 % had health literacy levels below the 9th grade reading level. This is problematic as much health promotion and medication adherence information is targeted to a tenth grade reading level, which may be inaccessible to many patients. Interventions to improve adherence through health literacy have the potential to require relatively few resources to implement, making them particularly important tools to combat medication non-adherence. Future interventions may target and/or oversample patients at greatest risk for health literacy-related medication non-adherence.

A LONGITUDINAL ANALYSIS OF THE EFFECT OF TOTAL OPIOID ANALGESIC DOSE ON SUBSEQUENT USE AND DURATION OF HOSPITALIZATION *Barbara J. Turner^{1,3}; Benjamin R. Ehler²; Yuanyuan Liang^{2,3}*

¹University of Texas Health Science Center at San Antonio, San Antonio, TX;

²University of Texas Health Science Center at San Antonio, San Antonio, TX;

³University of Texas Health Science Center at San Antonio, San Antonio, TX.

(Tracking ID #1937908)

BACKGROUND: High opioid analgesic (OA) doses for chronic non-cancer pain (CNCP) increase the risk of adverse events such as drug overdose and car accidents but it is not known whether these drugs are associated with an increased risk of future all cause hospitalization. Objective: To conduct a population-based study of the association of total dose of filled OA prescriptions (Rxes) in a baseline 6 month interval and patient age with any hospitalization and duration of hospitalization in the next 6 months.

METHODS: For persons enrolled >1 year from 1/2009 to 7/2012 in Aetna's national HMO (2.1 million), 278,975 persons aged 18 to 64 years were selected if they filled ≥ 2 Rxes for non-injectable Schedule II or III OAs. From claims and enrollment files for these subjects, a database was developed including demographics, encounters, ICD-9-CM codes, and filled Rxes. For this analysis, we selected persons aged 45–64, no cancer diagnosis (except basal cell) within 6 months of an OA Rx, and no OAs for opioid dependence. Follow-up after the first OA Rx was divided into 6-month intervals until 1/2012 (excluding incomplete intervals). The total morphine equivalent dose (TMED) was calculated from all filled OAs Rxes for each 6-month interval and categorized for analysis as none and approximate quartiles: NO risk (0 days); LOW risk (1–190 TMED); MEDIUM risk (191–450 TMED); HIGH risk (451–1830 TMED); and VERY HIGH risk (>1830 TMED). Days covered by filled Rxes for other drugs used for CNCP—benzodiazepines, zolpidem, and antidepressants—were analyzed per 6-month interval. From ICD-9 codes, we created indicators for five categories of CNCP, mental health conditions, and substance abuse. Repeated measures logistic regression was used for hospitalization (Y/N) and repeated measures Poisson regression was used for inpatient days. All analyses adjust for patient demographic, clinical, and treatment factors. No significant interaction was observed for OA risk and age; therefore, we only report results for OA risk.

RESULTS: The cohort totaled 109,292 persons with a mean age of 53.7 years (SD=5.5), 54.7 % female, and residence in South (46.9 %), West (16.8 %), Midwest (6 %) and Northeast (30.3 %). In the cohort's 253,531 six-month follow-up intervals, the proportion hospitalized was 6 % and median hospital days was 4 (IQR=3–6). For hospitalization, the adjusted odds ratio [95 % CI] for OA risk categories vs. NO risk were: VERY HIGH: 1.45 [1.38, 1.54]; HIGH: 1.15 [1.08, 1.21]; MEDIUM: 0.98 [0.93, 1.04]; LOW: 1.04 [0.98, 1.10]. For inpatient days, the incident rate ratio [95 % CI] for OA risk vs. NO risk were: VERY HIGH: 1.47 [1.34, 1.62]; HIGH: 1.10 [1.01, 1.20]; MEDIUM: 0.87 [0.80, 0.95]; and LOW: 0.95 [0.87, 1.03].

CONCLUSIONS: High or very high total dose of filled OA Rxes in a baseline 6-month interval is associated with an increased risk of subsequent hospitalization and more inpatient days independently of age, pain-related comorbidities, and other prescribed medications commonly used for pain. Reasons for these hospitalizations need to be examined to inform interventions to address this high use of costly inpatient care.

A MIXED METHOD STUDY OF THE QUALITY OF WRITTEN FEEDBACK BY ATTENDINGS OF INTERNAL MEDICINE RESIDENTS *Cynthia Kay¹; Jeffrey L. Jackson^{2,1}; Wilkins Jackson³*. ¹Medical College of Wisconsin, Milwaukee, WI; ²Zablocki VAMC, Milwaukee, WI; ³University of Wisconsin-Milwaukee, Milwaukee, WI. (Tracking ID #1920218)

BACKGROUND: Residents uniformly criticize the quality of feedback they receive. The purpose of this study was to evaluate the quality of feedback in an internal medicine residency program.

METHODS: Subjects for this retrospective analysis were Medical College of Wisconsin (MCW) internal medicine residents who completed residency training between 2004 and 2012. Over the 8 years, there were 6603 evaluations by 334 attendings. These evaluations followed ACGME guidelines and assessed residents in six domains and included a comment box. From these 6603 written comments, we randomly selected 500 and coded them using grounded theory methods. An initial coding tree was developed by two raters (CK, JLJ). Once the tree was saturated, 25 % of utterances were double coded with good inter-rater reliability (Spearman: 0.94). Utterances were further classified as high, moderate or low quality, also with good inter-rater reliability (Quadratic Kappa: 0.83). Focus groups were also conducted with medicine faculty and housestaff. First written comments were placed on notecards and the groups sorted the cards into high, moderate and low quality feedback. As they did this, they discussed the characteristics that merited this rating. The last few minutes of each focus group was spent reflecting and developing criteria for high, moderate and low quality feedback.

RESULTS: The majority of the attending's 500 written comments were rated as moderate quality (65 %); 22 % were rated as high and 13 % low. The most common type of feedback (29 %) was nonspecific comments, often about the resident's personality, 16 % about patient care, 14 % interpersonal communication, 7 % medical knowledge, 6 % professionalism, 4 % each commented on practice based learning or systems based practice. The majority of written feedback comments (88 %) were positive, 8 % were negative and 4 % were neutral; three ABIM domains were more likely to include negative comments (medical knowledge: OR: 3.5, 95 % CI: 2.2–5.6; Practice Based Learning: OR: 2.5, 95 % ci: 1.3–4.8, Systems Based Practice: OR: 4.6, 95 % CI: 2.5–8.3). Nonspecific comments and comments on resident's attitude or personality were much less likely to include negative comments than the other domains (nonspecific: OR: 0.22, 95 % CI: 0.13–0.39, attitude/personality OR: 0.53, 95 % CI: 0.34–0.82). Focus groups uniformly sorted quality into low, moderate and high quality feedback based on three criteria: specificity, quantitative ratings, actionable. Low quality feedback was nonspecific, moderate feedback had at least some specificity and high quality feedback included specificity plus either some aspect of quantification or was actionable. Despite the uniformity of the criteria espoused by focus groups, the inter-rater reliability between the focus groups was low, (quad kappa: 0.24).

CONCLUSIONS: Written feedback suffers from lack of balance, lack of specificity and lack of actionability. Much of it is focused on personality characteristics of the resident. While the focus groups developed nearly identical criteria for quality, agreement between the groups was low because the groups disagreed as to what constituted specific and actionable feedback. Residents are justified in expressing chagrin at the quality of feedback they are receiving.

A MIXED-METHODS EVALUATION OF A VA PATIENT-CENTERED MEDICAL HOME FOR SPECIALTY CARE *Michael Ho²; Catherine Battaglia¹; Leah M. Haverhals²; Katherine M. Fagan²; Jackie G. Szarka³; Rebecca Alexander³; George Sayre³; Christian Helfrich³; Susan Kirsh⁵; David Au³; David Aron⁶; Julie Lowery⁴*

¹Eastern Colorado Health Care System, Denver, CO; ²Eastern Colorado Health Care System, Denver, CO; ³Puget Sound Health Care System, Seattle, WA; ⁴Ann Arbor Health Care System, Ann Arbor, MI; ⁵Case Western Reserve University, Cleveland, OH; ⁶Louis Stokes VA Medical Center, Cleveland, OH. (Tracking ID #1938016)

BACKGROUND: The Veterans Health Administration (VA) implemented a pilot program called Specialty Care Neighborhood (SCN) to align with the VA's Patient Centered Medical Home to deliver comprehensive patient-centered care. SCN is a team-based specialty care model, in which teams of specialists engage in proactive and long term collaboration with primary care in order to provide coordinated, optimal care for Veterans with the greatest specialty care needs. SCNs were implemented at 25 VAs in 20 specialties including Heart Failure, Diabetes, Cancer, Pain, Orthopedic Surgery, and HIV. We completed an evaluation of the SCN initiative for the VA Office of Specialty Care (OSC).

METHODS: Findings are presented here from semi-structured interviews and staff surveys. A goal of the evaluation was to identify factors that differentiated four high

from two low performing sites as determined by OSC from regular site reports on implementation progress. The evaluation consisted of 27 semi-structured interviews with Primary Care Providers, specialists, and key stakeholders (administrators, chiefs of staff, and facility directors) at the participating sites. Additionally, SCN staff from the six sites returned 39 surveys about their experience with SCN. Interview and survey data were coded using the Consolidated Framework for Implementation Research.

RESULTS: SCNs were viewed positively. Participants from all sites described improved professional relationships and communication as well as improved quality and quantity of specialty services. Interviewees felt improved relationships led to increased job satisfaction and engagement. Participants expressed frustration as to lack of clarity regarding how to implement SCN, and despite this barrier, pulled together to creatively implement SCNs best adapted to meet local needs. In structured ratings of implementation facilitators and barriers, High performing sites, in contrast to low performing sites, engaged leadership, utilized a thoughtful planning process that allowed for ample implementation time, and used systems redesign techniques to streamline processes. Additionally, there were factors from interview data that facilitated implementation at both high and low sites: 1) positive knowledge and beliefs about the program; 2) obtaining patient and provider feedback; 3) recognizing patient needs; 4) active champions; and 5) ability to adapt the program easily. Common barriers included 1) problems with hiring staff, 2) lack of commitment to long-term staff funding, 3) lack of administrative support, 4) insufficient materials for facilitating implementation, and 5) coordination and communication challenges among different providers and services. Interview data and staff survey data were largely congruent. However, survey participants reported high leadership engagement despite interview data suggesting this was less positive among low performing sites.

CONCLUSIONS: The findings were used to identify areas on which to focus attention for improving dissemination of the program. Recommendations were based on factors that distinguished high from low performing sites and included recommendations to overcome barriers: 1) Provide opportunities for sharing best practices across sites; 2) Encourage innovation through site-based flexibility and individualization while limiting micromanaging; 3) Facilitate access to systems redesign expertise; 4) Minimize complexity by utilizing programs in place; and 5) Begin planning process early and involve all key stakeholders.

A MODEL TO PREDICT RISK OF CERVICAL ABNORMALITIES IN PRIMARY CARE Michael B. Rothberg; Bo Hu; Sarah Schramm; Kelly Nottingham; Glen Taksler; Xian W. Jin; Laura Lipold; Andrea L. Sikon. Cleveland Clinic, Cleveland, OH. (*Tracking ID #1937479*)

BACKGROUND: Cervical cancer screening tests are highly sensitive but have low specificity, resulting in high false positive rates among low-risk women. Although there are known risk factors for cervical cancer, there are no validated tools for assessing risk in primary care. Using data from electronic health records, we derived and validated a risk prediction model for cervical intraepithelial neoplasia grade 2 or higher (CIN2+) lesions.

METHODS: Our dataset included information on all women aged ≥30 years who underwent cervical cancer screening with cytology and human papilloma virus (HPV) testing at 33 physician practices associated with the Cleveland Clinic between 2004 and 2010. Patient risk factors at the time of screening (age, race, marital status, insurance type, smoking history, median income based on zip code and physician practice) were determined by reviewing the electronic health record. Pathology results were obtained from the Cleveland Clinic's pathology database (for patients who underwent colposcopy with biopsy) or by imputation (for patients with abnormal cytology who did not undergo colposcopy). Imputation was based on observed associations between patient risk factors, HPV and cytology results and CIN2+ status among women who underwent colposcopy. Using CIN2+ as our outcome, we then derived a hierarchical generalized linear model with a logit link that included all patient risk factors available before screening (i.e. not HPV or cytology results) as independent variables. We then stratified patients into tertiles of low, medium and high predicted risk of CIN2+. We then compared the actual rate of CIN2+ (either observed or imputed) in the low-risk tertile to an implied threshold value, which was based on combinations of HPV and cytology results for which colposcopy is typically not recommended. The threshold was 0.20 %, which is equivalent to the rate of CIN2+ among patients with low risk ASCUS and negative HPV. The final model was validated using 100 bootstrap iterations for the entire population and noting the proportion of low risk patients who had CIN2+.

RESULTS: The dataset included 99,388 women. Of these, 574 had pathology findings of CIN2+ and 175 had CIN2+ assigned by imputation (overall rate of CIN2+=0.75 %). The final multivariable model had a c-statistic of 0.73. All factors

but race were associated with CIN2+: older age (OR 0.69 per 5 years, 95 % CI 0.66, 0.73), Medicare vs. private insurance (OR 0.51, 95 % CI 0.34, 0.75) and higher income (OR 0.97 per \$5 K, CI 0.94, 0.99) were negatively associated, while being single vs. married (OR 1.50, 95 % CI 1.24, 1.82) and smoking (OR 1.66, 95 % CI 1.35, 2.04) were positively associated. Tertiles of predicted risk were 0.20 %, 0.53 %, and 1.51 %, with observed rates of CIN2+ over the same tertiles of 0.19 %, 0.52 %, and 1.53 %. Therefore, before cervical cancer screening, women in the lowest risk tertile had observed CIN2+ risk slightly below that of women with ASCUS and HPV negative (0.20 %). In 100 bootstrap iterations, the observed risk in the lowest tertile ranged from 0.13 to 0.25 % (IQR 0.18 % to 0.22 %).

CONCLUSIONS: A multivariable model based on data derived from the electronic health record was able to risk stratify women across an 8-fold gradient of risk for cervical abnormalities and to identify a large group of women who are at very low risk for cervical cancer and may not require screening. After further validation, use of a similar model could enable more targeted cervical cancer screening.

A NATIONAL SURVEY OF PATIENT CENTERED MEDICAL HOME INITIATIVES Samuel T. Edwards^{1,2}; Asaf Bitton^{3,4}; Johan S. Hong⁴; Bruce E. Landon^{4,5}. ¹Boston VA Healthcare System, Boston, MA; ²Harvard Medical School, Boston, MA; ³Brigham and Women's Hospital, Boston, MA; ⁴Harvard Medical School, Boston, MA; ⁵Beth Israel Deaconess Medical Center, Boston, MA. (*Tracking ID #1932105*)

BACKGROUND: The reorganization and improvement of primary care through the implementation of the patient-centered medical home (PCMH) is central to healthcare delivery system reform efforts. PCMH initiatives, often organized by health plans, states or multi-stakeholder groups, seek to create the appropriate context to promote transformation of participating primary care practices into medical homes by building learning collaboratives, providing practice coaching, and reforming physician payment to support medical home services. Although there has been expansion of PCMH activity across the country, the current national scope of PCMH initiatives remains undefined. To address this gap, we conducted a nationwide survey of PCMH initiatives. We describe their size, scope, organization and payment methodology and assess their approach to practice transformation and program evaluation.

METHODS: We performed a cross-sectional survey of all PCMH initiatives nationally that included payment reform as an operational feature. We identified initiatives for the survey from existing databases supplemented by formal literature review, internet searches, and by contacting known experts, state Medicaid directors, and representatives from all major national health plans. We included initiatives that were active as of February 1st, 2013 but excluded programs directed solely toward specific medical conditions or serious mental illness. The survey included descriptive questions including initiative start and end dates, numbers of participating practices, physicians and patients, and identity of key stakeholders. We asked about the selection process for practices to enter the initiative, the use of formal PCMH recognition, and payment methods. Finally, we asked about how initiatives facilitated practice transformation and plans for program evaluation. The survey was fielded from February 1st 2013–October 31st 2013 via web or telephone. Respondents were physicians, senior administrators, or senior health policy experts from each initiative. We present descriptive statistics to compare initiatives sponsored by commercial health plans, state Medicaid programs, and multiple payers.

RESULTS: Of 119 identified initiatives, we received 114 responses (96 % response rate). Forty-one programs were small commercial single payer initiatives, 29 were large single payer initiatives, 23 were Medicaid only and 21 were multi-payer. In total, the programs included 63,011 providers caring for 20,389,327 patients nationally. Small commercial programs had a median of 3,896 patients and typically included a small number of practices (median = 4). Large commercial single payer initiatives included a median of 160,000 patients, often covering most or all practices in a specific region or an entire state (median 105 practices). Medicaid initiatives were typically large statewide programs (median 224,040 patients) run directly by state Medicaid agencies. Multi-payer initiatives included a median of six health plans (IQR 4–7) with a median of 187,343 patients, and 68 practices. These initiatives included commercial health plans, Medicare and Medicaid. Formal PCMH recognition was required by 69 % of initiatives. Nearly half of initiatives use practice consultants (46 %) or learning collaboratives (48.7 %), but this was more common in multi-payer initiatives (90.5 % and 95.2 %, respectively). Nearly all initiatives had a formal evaluation plan (92 %). A combination of fee for service payments (FFS) for office visits, a per-member-per month care management fee (PMPM), and pay for performance bonuses was the most common payment structure (55 % of programs). Median PMPM was \$4.90 (range \$0.25–\$60.00), but was higher in multi-payer initiatives (median \$7.00). Since 2009, fewer initiatives are time-limited pilots, shared

savings programs are more commonly used, and more initiatives are performing formal evaluations (table).

CONCLUSIONS: In this national survey of PCMH initiatives, we demonstrate there has been a large expansion of PCMH activity over the last several years, with 114 initiatives representing over 60,000 providers and nearly 21 million patients in 2013. Initiatives are on average larger, feature more robust transformation efforts, and have higher care management fees. This expansion of PCMH initiatives suggests that the PCMH will continue to play an important role in national delivery reform efforts.

Comparison of PCMH initiatives in 2009 and 2013

	2009 (N=26)	2013 (N=114)
Total patients	4,971,070	20,970,277
Time limited initiatives (%)	62 %	20 %
Median patients per initiative	30,000	40,986
Number multi-payer initiatives	9	22
Median patients in multi-payer	39,000	146,636
Use Shared Savings	0 %	44 %
PMPM (range)	\$0.50-\$9.00	\$0.25-\$60.00
Use Learning Collaboratives and Consultants	15 %	37 %
Performing Program Evaluation	40 %	92 %

A PROFILE OF HOSPITALIZED SMOKERS AND THE CARE THEY RECEIVE Ellie Grossman¹; Alissa R. Link²; Erin Rogers^{2,3}; Binhuang Wang²; Scott Sherman^{2,3}. ¹NYU School of Medicine, New York, NY; ²NYU School of Medicine, New York, NY; ³VA New York Harbor Healthcare System, New York, NY. (*Tracking ID #1939163*)

BACKGROUND: Identification and treatment of patients who smoke is a priority treatment area for hospitals. Hospitalization can be a 'teachable moment' for patients contemplating behavior change, and they may be newly motivated by health consequences. Evidence suggests that appropriate treatment should begin during an inpatient stay and continue for at least four weeks post-discharge. To optimize success, treatment should include both counseling and medications. Patients with mental illness tend to smoke at higher rates than those without, and tend to die earlier of cardiovascular disease, but there is a paucity of evidence about the state of treatment offered to these patients. We aimed to describe the care offered to hospitalized smokers at two urban safety-net hospitals.

METHODS: As part of a randomized controlled trial of smoking cessation interventions focused on the post-discharge time period, we assessed the care for smokers hospitalized at two large public hospitals in New York City. Adult patients were eligible for study inclusion if they: smoked at least one puff of a cigarette in the past 30 days; spoke English, Spanish, or Mandarin; were not incarcerated or in police custody; were not pregnant or breastfeeding, and had a U.S. phone number. At the time of discharge, study staff reviewed participants' electronic medical records (EMR) for information about type of inpatient unit, history of medical or psychiatric illnesses, and tobacco treatment received during hospitalization and on discharge.

RESULTS: From July 2011 to December 2013, we enrolled 1486 study participants. 511 (35 %) were on psychiatric inpatient units and 934 (65 %) were on medical/surgical units (*n*=41 missing). Mean age was 47.9 years, 79 % were male. Of these patients, 17 % had EMR documentation of coronary artery disease, 12 % chronic obstructive pulmonary disease, 14 % asthma, 5 % cerebrovascular disease, 4 % congestive heart failure, 55 % significant alcohol or drug use history, and 10 % schizophrenia or schizoaffective disorder. We found EMR documentation that smoking status was assessed at admission in 1444 (97 %) and bedside counseling was provided in 1294 (87 %). Of those that received counseling, the EMR indicated that 1015 received it from nurses and 145 received it from physicians (for the rest the personnel was not specified). For 647 patients (44 %), physicians ordered smoking cessation pharmacotherapy during hospitalization (36 % NRT patch, 3 % NRT gum, 2 % NRT lozenge, 1 % other). On discharge, 274 patients (18 %) were prescribed cessation medication. Patients on inpatient psychiatric units were more likely to be counseled by their physician regarding smoking cessation (odds ratio (OR) 1.93, 95 % CI 1.20–3.09) and were more likely to be prescribed cessation medication in hospital (OR 3.21, 95 % CI 2.51–4.11) than were patients on non-psychiatric units. There was no association between type of inpatient service (psychiatric vs. non-psychiatric) and likelihood of prescription of smoking cessation medication at discharge.

CONCLUSIONS: At urban safety-net hospitals, patients who smoke have high rates of mental illness and substance use disorders. Although assessment and counseling are provided at relatively high rates, there is much room for improvement in prescribing smoking cessation pharmacotherapy in the hospital and on discharge.

A QUALITATIVE ANALYSIS OF HOSPITAL LEADERS OPINIONS ABOUT PUBLICLY REPORTED MEASURES OF HEALTH CARE QUALITY Sarah L. Goff^{1,2}; Tara Lagu^{2,1}; Amy S. Shatz²; Penelope S. Pekow²; Peter K. Lindenauer^{2,1}. ¹Baystate Medical Center/Tufts University School of Medicine, Springfield, MA; ²Baystate Medical Center, Springfield, MA. (*Tracking ID #1937659*)

BACKGROUND: Public reports of hospitals' performance on quality measures are intended to both encourage hospital leaders to stimulate improvement activities and to enable consumers to make more informed decisions about where to seek care. How effective public reporting is at fostering quality improvement may be influenced by whether and to what extent hospital leaders find the measures valid and meaningful. We sought to qualitatively describe hospital leaders' views regarding quality measures reported on the Centers for Medicare and Medicaid Services' Hospital Compare website.

METHODS: We mailed or e-mailed a 21-item questionnaire to the chief executive officer and the senior executive responsible for quality at a stratified random sample of U.S. hospitals. Stratification was based upon performance on selected quality measures to achieve a balance of high, average and low performers. While the quantitative portion of the study assessed attitudes regarding publicly reported quality measures, opinions regarding quality measures were elicited using an open-ended prompt at the end of the survey, "Please share your additional thoughts about publicly reported measures of healthcare quality, including strengths or weaknesses of current measures, ideas for new measures, etc." We qualitatively analyzed responses to this prompt, identifying the presence and frequency of pertinent themes in an iterative process.

RESULTS: Leaders (*n*=480) from 380 of the 630 hospitals surveyed (60 %) completed the questionnaire. Of those who completed the questionnaire, 146 leaders from 131 hospitals responded to the open-ended prompt. The majority of respondents to the open-ended prompt were chief executive officers (27 %), chief quality officers or vice presidents of quality (17 %) or chief medical officers (19 %). Half of the responses to the prompt came from leaders at urban hospitals and 68 % were from leaders at non-teaching hospitals. Most respondents were from hospitals that had fewer than 200 beds (41 %), with 23 % from hospitals with more than 400 beds. Forty-one percent of the respondents' hospitals had performance scores higher than the national average and 27 % scored lower than the national average. Major themes identified included: 1) Positive views of the value of quality measures (12.5 %, e.g., measuring quality can stimulate change and enhance patient engagement); 2) Concerns regarding the validity and utility quality measures (63 %, e.g., measures fail to measure what is important, inadequate risk-adjustment); 3) Challenges to improving quality scores (e.g., inability to impact factors affecting care outside of the hospital, such as patient adherence to prescribed medication); and 4) Recommendations for improving measures (e.g., compare similar hospitals to each other). Many of the positive views expressed were general support for the concept of measuring quality: "Oversight and comparison with peers/standards is necessary and beneficial." Criticisms of quality measures included concerns about whether doctors can actually influence change in the entities measured: "...the scores for which the doctors are held accountable are subject to profound influence by others besides the doctor to whom the score is attributed." Challenges described included lack of resources: "Resources are stretched to the limit with meaningful use and data reporting!" Recommendations for improvement in quality measures included an emphasis on the continuous learning cycle, suggesting new targets for quality improvement should be identified as older measures reach acceptable levels of compliance: "...care measures should evolve as compliance becomes ingrained thus continuing the improvement cycle."

CONCLUSIONS: Among hospital leaders who responded to an open-ended prompt eliciting their views about quality measures some expressed support for the concept of measuring quality, while the majority offered criticisms concerning the validity and utility of current quality measures or described challenges to improving quality. As current quality measures are reassessed and new measures developed, the concerns of those responsible for implementing system changes to address quality should be taken into account.

A QUALITATIVE ANALYSIS OF PATIENT FACTORS ASSOCIATED WITH HOSPITAL READMISSION Colleen M. Rafferty; Tyler Sechrist; Heather Stuckey; Nicole Swallow; Cynthia H. Chuang. Penn State Hershey Medical Center, Hershey, PA. (*Tracking ID #1936483*)

BACKGROUND: Given the focus on hospital readmissions as a quality indicator, health care organizations nation-wide are interested in finding ways to reduce hospital readmissions. Existing readmission prediction models have relied mainly on clinical

and administrative data. A weakness in these methods is that they are not informed by the patient perspective. Exploring patient experiences with readmission may broaden our understanding of what leads to readmission, thereby facilitating a more patient-focused approach to identifying high-risk patients, and enabling institutions to allocate resources to the highest risk patients and to the most cost-effective and efficacious interventions. We conducted qualitative interviews with readmitted patients to identify more precisely the patient-centered factors associated with readmission.

METHODS: We conducted semi-structured interviews with a convenience sample of hospitalized patients readmitted to the Internal Medicine service within 30 days of discharge to home from a previous hospitalization at our institution, a 500-bed tertiary care academic medical center. Patients were eligible if they received their primary medical care within our medical system and were readmitted from June–August 2011 ($n=19$). Open-ended interview questions addressed the patients' perspectives on the medical care they received during the previous admission, access to outpatient care, the patient's knowledge of his/her medical conditions and treatments, ability to provide self-care, and social support available to them. We also encouraged the patient to discuss from his/her perspective what could have been done differently to help prevent the readmission. The contents of the interviews were transcribed and a thematic analysis was conducted. We also conducted a medical chart review to determine if the patient had a scheduled follow-up appointment that they attended.

RESULTS: We found that the majority of patients had a limited understanding of their medical conditions and their medications. Many patients relied heavily on an advocate (family member or friend) to assist them in their disease management. The vast majority of patients had identified advocates, but we found that not all advocates were effective in providing the needed assistance. Also, most patients did not view their health as under their control, but identified an external locus of control (i.e. the doctors, the disease process, God). All patients identified a primary care physician, and all had been scheduled for follow up appointments within 5–24 day after discharge, but 9 of 19 patients were readmitted prior to their scheduled appointment (8/19 readmitted within 7 day, 10/19 within 10 day). The majority of patients did not feel their readmission was preventable, but attributed it to the disease process, or an issue that was not viewed by the patient as avoidable or predictable.

CONCLUSIONS: These findings suggest potential patient-centered factors that may be used to help identify patients at high risk for readmission: insufficient understanding of medical condition or medications, lack of an effective advocate, a belief that one's health is not under the one's own control, and lack of timely access to outpatient follow up care. Early assessment of these risk factors may help target appropriate interventions to high risk patients to help prevent hospital readmission.

A QUALITATIVE ASSESSMENT OF CPOE AND THE EFFECTS OF VARIATION IN DRUG NAME DISPLAY Alexandra Robertson¹; Arbor J. Quist¹; Thu-Trang Thach¹; Lynn A. Volk²; Adam Wright^{1,3}; Shobha Phansalkar^{1,4}; Sarah P. Slight^{1,5}; David W. Bates^{1,3}; Gordon D. Schiff^{1,3}. ¹Brigham and Women's Hospital, Boston, MA; ²Partners HealthCare Systems, Inc., Wellesley, MA; ³Harvard Medical School, Boston, MA; ⁴Wolters Kluwer Health, Indianapolis, IN; ⁵The University of Durham, Durham, United Kingdom. (Tracking ID #1938546)

BACKGROUND: Previous work suggests that prescribing errors account for the highest proportion of medication errors (Lisby, 2010) and that one in every four reported in the U.S. can be linked to drug name confusion (Lambert, 1999). Computerized provider order entry (CPOE) has been widely proposed, implemented, and shown to reduce errors associated with traditional, handwritten, medication prescribing. However, CPOE has not fully lived up to its predicted benefits and many attribute these shortfalls to suboptimal design of systems that are “neither interoperable nor easy to use” (Kellerman, 2013, Health Affairs). Given recent calls for CPOE performance testing post-implementation (Thompson, 2010 & Bates, 2013) and the proportion of medication errors which occur during the prescribing phase, we undertook a study to assess drug name design and display issues in CPOE including: look-alike-sound-alike pairs, similar name adjacency errors, font, and visual display to better understand their potential to contribute to medication errors.

METHODS: As part of an FDA Task Order, this qualitative study assessed 10 leading vendor and home-grown CPOE systems in six major U.S. academic medical centers via remote walk-throughs and on-site visits. To standardize assessment, the team developed and iteratively refined a CPOE Assessment Tool (CAT) relating to 18 elements defined by the FDA to systematically test the potential for drug name/identification errors across various stages of the medication ordering process. This tool incorporated specific medication ordering, review, and deletion scenarios used to

guide system assessments with a series of “regular” and “expert” users of these systems. Outputs from these evaluations were recorded from each system using screen shots, video and audio transcripts of user and designer comments. Recordings were transcribed, analyzed, and used to inform the content of onsite visits to each medical center to obtain additional system information from medical leadership, IT experts, users, and pharmacists. Inter- and intra-system characteristics were analyzed descriptively for patterns, themes, and variations.

RESULTS: We identified a variety of ways drug names are displayed in CPOE systems that could potentially contribute to medication errors. Recurrent issues and themes that emerged included: (a) Brand versus generic name: Presentation of brand and generic names varied both across and within systems depending on task functionality. In nine of the ten CPOEs assessed, for example, one brand name search (Plavix) yielded results displaying the drug in eight different ways. Some systems used all caps, some only initial caps, some used both. Some were inconsistent in the drug name searched and drug name returned. One system displayed two columns which listed both the brand and generic names, others included only one, and others presented one or the other parenthetically, based on the search term. One system allowed ordering by generic name only. If one searched by brand name, the medication did not appear; we observed end user frustrations resulting from inability to search for and find desired drugs searched non-generically. Systems also used varied methods to display brand and generic options to steer prescribing towards preferred products (typically the generic). (b) Combination products: In most systems, searching for a combination drug often yielded the brand name with the ingredients listed parenthetically. We rarely saw systems provide explanations of ingredient strengths. In some systems, searching the brand name yielded only the brand name, without its generic ingredients. (c) Drug-name modifiers: Across systems, drug modifiers seemed to have some consistency in both representation and display. Drug modifiers appeared primarily at the end of the drug name, in all caps, and were abbreviated (e.g. XR, DS, etc.). They were rarely truncated. (d) Extraneous additions to drug name fields: Across systems, we observed several instances of non-systematically populating (jerry rigging) name fields with additional information ranging from drug indication to which facility the drug could be ordered from. (e) Font, text size, capitalization: These all varied widely with no standardized approaches seen both across and often within systems.

CONCLUSIONS: There is little consistency in the ways that leading CPOE systems search for and present drug names. This lack of standardization was seen both across systems and often within a single system or institution's CPOE systems. Brand vs. generic, combination products and drug name modifiers were particularly inconsistent, each presenting the potential for user frustration, confusion, and erroneous orders.

A QUALITATIVE STUDY EXPLORING THE VULNERABILITIES OF COMPUTERIZED PHYSICIAN ORDER ENTRY SYSTEMS Sarah P. Slight^{1,2}; Tewodros Eguale^{1,3}; Mary Amato^{1,4}; Andrew C. Seger⁴; Diana L. Whitney⁵; David W. Bates^{1,6}; Gordon D. Schiff^{1,6}. ¹Brigham and Women's Hospital, Boston, MA; ²Durham University, Stockton on Tees, United Kingdom; ³McGill University, Montreal, QC, Canada; ⁴MCPHS University, Boston, MA; ⁵Baylor College of Medicine, Houston, TX; ⁶Harvard Medical School, Boston, MA. (Tracking ID #1935926)

BACKGROUND: Computerized Physician Order Entry (CPOE) systems can prevent medication errors in both inpatient and outpatient settings. Depending on how they are designed, however, they can fail to optimally prevent various prescribing errors or introduce new errors. The Institute of Medicine report Health IT and Patient Safety: Building Safer Systems for Better Care recommended that specific examples of potentially unsafe processes and risk-enhancing interfaces be identified and shared amongst the health IT community. This study aims to test the vulnerabilities of a wide range of CPOE systems to different types of medication errors, and to develop a more comprehensive understanding of how CPOE human factors design could be improved.

METHODS: As part of a National Patient Safety Foundation-funded project, we examined a range of leading vendor and home grown CPOE systems (e.g., Cerner; Epic; Medi-tech; LMR; BICS; GE Centricity) in diverse organizations in United States and Canada. Typical users at each of 16 sites were asked to enter 13 different orders on test patients based on scenarios of previously reported CPOE errors. Users were encouraged to use both usual practice and, where-needed, workarounds to enter the erroneous orders, as well as reflect on their overall knowledge and experience of using their system. A research pharmacist and research assistant independently observed test users enter each order and rated the ease or difficulty of these entries using standardized operational definitions.

RESULTS: Ease of entry of erroneous orders and the generation of alert warnings in different CPOE systems was highly variable and appeared to depend on a number of factors including how the order information was entered (i.e., in a structured or unstructured way); whether a specific alert functionality (e.g., duplicate-drug checking) was operational in the system; and which drugs or drug combinations were included in the clinical decision support algorithms. Test users found the wording of many of the alert warnings confusing and expressed frustrations with the way irrelevant warnings appeared on the same screen as those more relevant to the current order. The timing of alert warnings also differed across CPOE systems, with dangerous drug-drug interaction warnings displayed, for example, only after both Imdur® (isosorbide mononitrate) and Revatio® (sildenafil) had been entered and the order signed off in two CPOE systems. Alert warnings also varied in their level of severity in different systems even within the same institution (e.g., test user was presented with a hard stop alert warning in the inpatient system after entering Lovenox® (enoxaparin sodium injection) 40 mg subcutaneous daily followed by a second order for Lovenox® 100 mg subcutaneous twice daily, whereas the equivalent outpatient system produced an alert for the same order that was easily overridden). Test users commented on how there may be situations where they needed to prescribe the same drug twice, requiring workarounds such as entering the brand name of the drug for the morning dose and the generic name for the evening dose, to avoid getting duplicate drug alert warnings.

CONCLUSIONS: We found a high degree of variability of vulnerability in ordering and alerting between different CPOE systems. Detailed qualitative analysis of both the observed CPOE functionality and users think-aloud comments provided rich insights into the ways both systems and users were susceptible to ordering errors. System developers and users need to be aware of these vulnerabilities and build in protection strategies to re-engineer their systems to ensure safer prescribing.

A RANDOMIZED TRIAL OF A COMMUNITY HEALTH WORKER LED INTERVENTION TO IMPROVE DIABETES INTERMEDIATE OUTCOMES AMONG LATINOS PATIENTS WITH POORLY CONTROLLED DIABETES
 Olveen Carrasquillo; Yisel Alonzo; Cynthia Lebron; Natalie Ferras; Ernesto Reyes-Arrechea; Hua Li; Sonja Kenya. University of Miami, Miami, FL. (*Tracking ID #1936786*)

BACKGROUND: Diabetes disproportionately impacts Latinos. Community Health Workers (CHWSs) are one approach that may improve health outcomes in this population. However, evidence from rigorous randomized studies is limited.

METHODS: The Miami Health Heart Initiative examined the impact of a comprehensive community health worker (CHW) intervention on diabetes intermediate outcomes of systolic blood pressure (SBP), lipids (LDL) and Hemoglobin A1C (HbA1c). We recruited 300 Latino patients with poorly controlled diabetes (HbA1c>=8.0 %) ages 35–65 from the primary care clinics of Miami-Dade county's public hospital. Subjects were randomized to usual health care or a comprehensive structured CHW 1 year intervention consisting of home visits, phone calls and group education sessions. The intervention included patient navigation as well as assistance with social and non-medical needs. An RA blinded to group assignment conducted initial and follow-up evaluations at 12 months. We used linear mixed models to statistically test for the impact of our intervention on outcomes using intention to treat analyses.

RESULTS: The mean age of our patients was 56+7 years, 55 % were female and mean BMI was 31.6+7.4 kg/m². Over half (55 %) were sedentary (IPAQ) and median daily fruit and vegetable was two (BRFSS). Cubans made up 29 % of our sample with no other Hispanic ethnic subgroup representing over 15 % of the sample; 47 % of respondents scored the lowest possible acculturation score (Marin-Marin). Intervention patients received a median of five home CHW visits and 25 phone calls; 84 % of intervention group participants had at least 12 CHW contacts over the course of the year. Participation at group session was more skewed with 52 % of participants not attending any sessions. Of those that attended at least one session, average attendance was four sessions per participant. At 1 year the retention rate was 72 % and similar in both arms. Data on outcomes by group is shown in Table 1.

CONCLUSIONS: In a heterogeneous Latino population with poorly controlled diabetes, a rigorous CHW intervention resulted in statistically and clinically meaningful changes in HbA1C but not in blood pressure or lipids. The impact of the intervention on the latter two outcomes may have been limited by the fact nearly half of patients were at the SBP and LDL targets prior to the intervention.

A REDUCTION IN TELEMETRY ORDER DURATION DOES NOT CHANGE TELEMETRY ORDERING FREQUENCY AND REDUCES UTILIZATION Joel Boggan^{1,2}; Ann Marie Navar-Boggan⁴; Ryan D. Schulteis^{3,2}; David Sime^{6,5}; ¹Durham Veterans Affairs Medical Center, Durham, NC; ²Duke University Health System, Durham, NC; ³Durham Veterans Affairs Medical Center, Durham, NC; ⁴Duke University Health System, Durham, NC; ⁵Duke University Health System, Durham, NC; ⁶Durham Veterans Affairs Medical Center, Durham, NC. (*Tracking ID #1940176*)

BACKGROUND: American Heart Association guidelines for appropriate use of telemetry have not decreased inappropriate use of in-hospital cardiac monitoring. We evaluated how changing the default order set for telemetry affected overall telemetry utilization.

METHODS: The computerized ordering system at the Durham VA Medical Center was changed so that the maximum number of hours of cardiac monitoring was reduced by 33 %, from 72 to 48 h, before requiring a renewal order. No other intervention or general education about telemetry appropriateness was done. We compared the frequency of orders/week for telemetry and duration of cardiac monitoring for 12 weeks before through 6 weeks after this intervention. To assess the safety of the intervention, we measured the number of rapid response team (RRT) or code events occurring at any time during the hospital stay of general medical or general surgical patients. We compared event rates on telemetry before and after the intervention.

RESULTS: Over a 4-month period, there were 1051 telemetry orders placed for general medical or surgical patients before the intervention and 450 after. The average number of orders/week did not differ significantly before vs after the reduction in telemetry order duration (88 +/- 10 vs. 75 +/- 22 orders/week, p=0.11). The mean duration of telemetry was reduced by 32 %, which was the same percent reduction required by the change in policy (mean reduction in telemetry time decreased from 64 +/- 3.1 h/patient to 44 +/- 1.2 h/patient, p<0.01). The rate of code events and rapid response team events in hospitalized general medical or surgical patients decreased from 2.5 events/week to 2.2 events/week. Only seven RRT/code events occurred in patients on telemetry prior to the intervention, while one RRT/code event occurred in a patient on telemetry after the intervention (p=0.28).

CONCLUSIONS: A simple change in the default maximum number of hours a provider can prescribe cardiac monitoring before requiring a renewal order led to a dramatic decrease in telemetry utilization. Although the number of orders for patients to receive cardiac monitoring was unchanged, the duration of cardiac monitoring dropped substantially. Even with less monitoring, we found no increase in the rate of adverse events. Similar reductions at other medical centers may reduce telemetry utilization, technologist and nurse staffing requirements, and cost while preserving patient safety.

A RESIDENT INITIATIVE TO INCREASE USE OF NALTREXONE FOR ALCOHOL USE DISORDER AT A SAFETY NET HOSPITAL Maria E. Otto¹; Jeffrey K. Hom¹; Shilpa M. Shah¹; Natalie C. Young¹; Weston S. Fisher²; Edgar Pierluissi¹; ¹University of California San Francisco, San Francisco, CA; ²University of California San Francisco, San Francisco, CA. (*Tracking ID #1939058*)

BACKGROUND: Alcohol use disorder (AUD) is extremely common at San Francisco General Hospital (SFGH), with nearly one in four inpatients on the Medicine service affected. These patients frequently present to the Emergency Department (ED) with alcohol-related falls, seizures, and symptoms of

withdrawal. Their 30-day readmission rate is 16 %, above the 13 % for the remainder of the hospital. Hospitalization provides a window of opportunity to help this vulnerable population, as patients are often motivated to make changes following an alcohol-related illness but are frequently without primary care doctors. Despite the effectiveness of naltrexone, an inexpensive, FDA-approved medication for treatment of AUD, it has been underutilized. A pilot intervention in 2011 at SFGH increased prescriptions of naltrexone to eligible patients at discharge, but was not sustained.

METHODS: A resident-led, quality improvement (QI) project was implemented in February 2013 to 1) sustainably increase the prescribing of naltrexone to eligible inpatients with AUD upon discharge and 2) to measure the effect of the intervention on ED visits and readmissions within 30 days. The intervention 1) identified inpatients with AUD via the electronic handoff system, 2) educated providers about naltrexone, 3) prompted providers to prescribe naltrexone to eligible patients at discharge planning rounds, and 4) utilized principles of QI to continuously evaluate and improve the intervention. Data were collected via retrospective chart review to identify patients with AUD and determine eligibility for naltrexone. Among patients with AUD, number of ED visits and readmissions within 30-days of discharge were also obtained.

RESULTS: Among 118 patients with AUD identified between March 1 and April 15, 2013, 43 % ($n=51$) were eligible for naltrexone. Following the initial intervention, naltrexone offering increased from 2 to 58 % of eligible patients. This effect was sustained through continuous cycles of improvement, with 67 % of patients offered it most recently. Compared to patients not prescribed naltrexone ($n=31$), patients prescribed the medication ($n=20$) had 30-day readmission rates and hospital visits that were 74 % and 88 % lower, respectively.

CONCLUSIONS: These results are promising and suggest that an intervention to systematically identify and offer treatment to patients with AUD is important in caring for our patient population and decreasing hospital utilization. Additionally, this QI initiative demonstrates that a deep-rooted problem can be addressed with the commitment of an interdisciplinary team, which can include a rotating group of trainees. By assessing the effect of this intervention on hospital utilization, the project shows that measuring true outcomes, rather than just processes, can help build a business case for sustainability. Next steps include 1) expanding the intervention to other hospital services, 2) ensuring the safe transition of patients on naltrexone from the hospital setting to their outpatient providers, and 3) collaborating with hospital leadership to improve systems to identify and offer treatment to all patients with AUD.

A ROLLING, INTEGRATED EVIDENCED-BASED MEDICINE CURRICULUM'S IMPACT ON EVIDENCE-BASED PRACTICE SKILLS, KNOWLEDGE, BEHAVIOR AND ATTITUDES ON INTERNAL MEDICINE STUDENTS AND RESIDENTS AT THE WASHINGTON, DC VETERANS AFFAIRS MEDICAL CENTER Matthew Tuck; Samantha McIntosh; David Marion. Department of Veterans Affairs Medical Center, Washington, DC. (*Tracking ID #1941446*)

BACKGROUND: Teaching evidence-based medicine (EBM) skills to students and residents has become an imperative for medical education. The AAMC made recommendations to incorporate problem-based clinical skills in medical schools' curricula. Similarly, the Next Accreditation System of the ACGME requires that residency programs train and evaluate residents in practice-based learning and improvement. Developing effective techniques for integrating these practices across the years of medical education remains a challenge for medical schools and residency programs.

METHODS: We developed a rolling EBM curriculum for medical students and residents rotating through the Medical Service of the Washington, DC Veterans Affairs Medical Center (VAMC) that provides repeated opportunities for students and residents to learn, practice, and evaluate their skills within the context of real-time patient care. The curriculum is integrated into morning report over the course of a month-long rotation. Using a patient case on the wards, learners are guided through the process of formulating a PICO question, searching the literature to find an article that answers the question, appraising the validity of the article and applying the literature to the case. The aim of the study was to evaluate the curriculum on learners' self-reported patient care practices, attitudes and knowledge using validated rubrics. We hypothesized that exposure to the curriculum would improve learners' EBM-related patient care practices, attitudes and knowledge. Using a before-and-after design, consented learners were given questionnaires. We used validated rubrics on attitudes and behavior as well as a rubric to assess EBM knowledge (the so-called Berlin

Questionnaire) at the beginning and end of their rotation at the VAMC. Incentives were provided for completion of the questionnaires. Means, standard deviations, percentages and univariate paired t-tests were calculated for pre- and post-exposure scores. The research was funded by a Medical Education Research Grant awarded by George Washington University.

RESULTS: 231 residents and students were exposed to the curriculum. Sixty-three learners completed the pre-curriculum questionnaire and 21 completed both the pre- and post-curriculum questionnaires. Up to 74 % of respondents had never received formal education on EBM prior to their rotation at the VAMC. Mean scores on attitudinal and belief questions improved after exposure to the curriculum, but to a non-significant level. Similarly, knowledge of EBM, as assessed by the Berlin Questionnaire, improved to a non-significant level (pre-curriculum mean score 4.5, post-curriculum mean score 5.3, $p=0.10$). A regression was conducted to determine if the number of days between the pre and post-curriculum assessment predicted improved performance on the Berlin Questionnaire and was non-significant ($p=0.13$).

CONCLUSIONS: We successfully implemented a rolling, integrated EBM curriculum for internal medicine students and residents. Attitudinal, behavioral and knowledge scores improved to a non-significant level after the month-long exposure to the curriculum. The lack of significant findings may be in part due to small sample size.

A SALARY EQUITY STUDY: DIFFERENCES BY GENDER AND RACE, DEPARTMENT OF MEDICINE, UNIVERSITY OF MINNESOTA Anne Joseph; Wesley Miller; Jeremiah Menk; Stewart McMullan. University of Minnesota, Minneapolis, MN. (*Tracking ID #1938954*)

BACKGROUND: Salary inequities for female faculty have been documented in many academic disciplines.

METHODS: The University of Minnesota Department of Medicine (DOM) conducted cross-sectional studies in 2011, 2012, and 2013 with the objective of examining gender equity issues related to salary ($n=165$, $n=196$, and $n=213$ respectively). A pre-specified multivariable linear regression was used to adjust the salary comparison between men and women and Whites and non-Whites. The analysis included the following variables: gender, race, academic rank (and time in rank), leadership roles, degree(s), number of ABIM certifications, time from highest degree to current position, percent clinical effort, and subspecialty.

RESULTS: In 2011, 8 % of women were full Professors compared to 35 % of men. Leadership roles were held by 7 % of women compared to 19 % of men; similar differences in career characteristics were observed across all 3 years. The unadjusted mean salary for women was \$69,717–\$76,009 lower compared to men depending on the year. In 2011, 2012, and 2013 the adjusted mean comparisons for women vs. men were \$-10,513, -\$9,377, and -\$16,132 respectively. For non-Whites vs. Whites the comparisons were -\$9,018, -\$741, and -\$13,002. R-squared values for the models were between 0.757 and 0.767. As predicted, the model confirmed that the following were associated with increased salary: a PhD or Masters in addition to MD degree, number of ABIM certifications, rank, time variables, and holding a leadership position. For clinicians, procedural subspecialties (cardiology, gastroenterology, pulmonary, renal) conferred higher salaries than hematology-oncology-transplant, endocrinology, rheumatology, infectious disease, general internal medicine (in that order).

CONCLUSIONS: Gender differences persisted over the 3-year period despite preferential salary adjustments for women. Professional accomplishment characteristics do not fully explain faculty salary differences by gender and race. In response, the DOM has formed a Salary Equity Committee to systematically address these differences abiding by principles of transparency, simplicity, value of clinical, educational and research missions, validated benchmarks of productivity, equal access to leadership positions and supplemental income, and sustainability.

Adjusted Mean Comparisons

	2011	2012	2013
R-squared	0.767	0.757	0.759
Sex			
Women vs. men	-\$10,513	-\$9,377	-\$16,132
Race			
Non-White vs. White	-\$9,018	-\$741	-\$13,002

A SIMPLE SCREENING METHOD TO DETECT MALIGNANCY USING RED CELL DISTRIBUTION WIDTH (RDW) Hiroaki Wakakuri; Toshihiko Ohara; Makoto Suzuki; Sonoko Kirinoki; Naoko Onodera; Takashi Araki; Hideya Hyodo; Makoto Kawai; Masahiro Yasutake. Nippon medical school, Bunkkyokendangi, Japan. (*Tracking ID #1928358*)

BACKGROUND: RDW is rapidly calculated parameter using an automatic cell counter. Recent studies showed that RDW is strongly associated with prognosis in disorders such as chronic heart failure, idiopathic pulmonary fibrosis, sepsis, various cancer, and chronic kidney disease. However, it is still unclear that the relationship of RDW and diagnosis of malignancy. The aim of this study is to evaluate the usefulness of RDW to screening malignancy at the first visit outpatient clinic.

METHODS: Fifty one consecutive patients diagnosed as malignancy at ER and general internal medicine of our hospital were reviewed in the period between September 2012 and September 2013. Fifty one patients, matching age and sex, with common diseases, including hypertension and dyslipidemia were assigned to control group. The patients complicated severe anemia (Hb<9.0), chronic heart failure, chronic inflammation disease, with a dosing history of medication that have effect on RDW were excluded from control group. RDW was calculated using an automatic cell counter (Sysmex XE-5000). We also measured Hb, BUN, Cre, TC, albumin and CRP at the same time. The receiver operating characteristic (ROC) curve showed the best cut-off value of RDW for predicting malignancy.

RESULTS: Malignancy group (age 67.8 [24–88], man 27, woman 24) was classified into the digestive organs n 26 (gastric ca, colon ca, cecal ca, vater ca, HCC, GIST), hemopathy n 10 (malignant lymphoma, multiple myeloma, AML), respiratory organs n 6 (lung ca), gynecologic disease n 3 (ovarian ca, uterine ca), urinary organs n 3 (prostate ca, renal pelvic ca), breast cancer n 2, and liposarcoma n 1. Control group (age67.4 [28–86]) included 27 men and 24 women. Malignancy group had lower Hb and alb values than control group, and higher CRP values than control group (Hb: 12.0 [5.0–17.3] vs 13.6 [10.5–16.9], albumin: 3.64 [2.6–4.9] vs 4.21 [3.2–4.8], CRP: 3.33 [0.03–21.3] vs 0.37 [0.01–2.88], $P<0.05$). There was no strong correlation between the RDW and other parameters (vs BUN r 0.096, vs Cre r 0.071, vs TC r -0.284, vs CRP r 0.182, vs albumin r -0.437, vs Hb r=-0.537). RDW of malignancy group (14.6 [12.6–25]) was significantly higher than RDW of control group (13.3 [12.2–15.6]), ($P<0.05$). Using ROC analysis (AUC=0.744), RDW of 13.9 % was the best cut-off value for predicting malignancy with a sensitivity of 58.9 % and a specificity of 78.5 %.

CONCLUSIONS: Our result shows that RDW of malignancy group is significantly higher than control group. It is not enough to discriminate patients with malignancy diseases between healthy persons by just RDW value, but an elevated RDW>13.9 % value is a reliable additional predictor for screening malignancy at the first visit outpatient clinic.

A STRUCTURED REVIEW OF BENEFIT AND HARM DATA IN CANCER SCREENING GUIDELINES AND POINT-OF-CARE CLINICAL RESOURCES: DO CLINICIANS HAVE THE INFORMATION THEY NEED? Tanner Caverly; Elyse Reamer; Rodney A. Hayward; Michele Heisler; Angela Fagerlin. University of Michigan Medical School, Ann Arbor, MI. (*Tracking ID #1939040*)

BACKGROUND: Data on the absolute benefits and harms of preventive interventions represent essential information for clinicians. Clinicians cannot practice informed or shared decision making if they lack ready access to this information, which is needed to help weigh trade-offs between potential benefits and harms. We might expect that transparent quantification of potential benefits and harms would be provided in prevention guidelines and point-of-care resources (such as UpToDate©), but to date, a systematic assessment of whether these clinical resources provide this important clinical information has not been conducted. We sought to address this gap by conducting a review of current cancer prevention guidelines and point-of-service resources to examine what information they provide on the chance of benefit and the potential for harms.

METHODS: We reviewed all recommendation statements related to cancer prevention and screening from the United States Preventative Services Task Force (USPSTF), excluding statements rated I for insufficient evidence, pediatric and adolescent guidelines, and those only discussing counseling interventions. To capture other non-USPSTF guidelines in the same topic areas, we examined within the National Guidelines Clearing House (NGC) all discrete guidelines developed by US organizations. We also searched two popular point-of-care clinical resources (UpToDate© and Dynamed). A standardized abstraction form was iteratively created.

We abstracted basic guideline demographic data and information about how benefits and harms are presented.

RESULTS: We reviewed 11 cancer prevention guidelines from the USPSTF, 19 guidelines from other organizations within the same cancer-prevention areas, 15 related articles from Dynamed and 14 from Up-to-Date. These resources contained 114 separate recommendations, 77 of which described recommendations for the use of the preventive service in at least some sub-populations (positive recommendations). Among the positive recommendations, 31 % (24 out of 77) simply made a recommendation without mentioning any estimate of the chance of benefit. Twenty-seven percent (21 out of 77) presented the benefit as an absolute risk reduction. Regarding the potential for harm inherent in any intervention, 48 % (37 out of 77) of the recommendation statements did not mention any harms and an additional 18 % (14 out of 77) mentioned but did not quantify those harms. Of the 27 % (21 out of 77) that quantified both potential benefits and potential harms, 19 % (4 out of 21) presented benefit as a relative risk reduction (larger number) while presenting harm as an absolute risk increase (smaller number)—a format known as mismatched framing that exaggerates the relative magnitude of the benefit compared with the harm. Only 21 % ($n=16$; 10 from guidelines and 6 from point-of-care resources) of the 77 positive recommendations quantified both the potential benefits and harms as absolute risks so that they could be directly compared.

CONCLUSIONS: Guidelines and point-of-care clinical resources for cancer prevention interventions frequently do not provide needed information on the chance of the intervention resulting in patient benefit or the potential of being harmed. The resources we reviewed may not represent all of the resources that clinicians use in daily practice. However, other resources are unlikely to present this information if the resources we reviewed did not. After undertaking the effort to summarize and rate the quality of evidence supporting use of a preventive service, evidence review bodies should also seek to quantify and present the potential benefits and harms of the proposed intervention. A satisfactory way to present this data would be to depict estimates of absolute benefits and harms together in a single table within the guideline—as is promoted by the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) approach.

ACCEPTABILITY AND FEASIBILITY OF HPV SELF-SAMPLING FOR CERVICAL CANCER SCREENING AMONG PATIENTS AND PROVIDERS IN TWO SAFETY-NET INSTITUTIONS IN MIAMI Kumar Ilangoan¹; Erin N. Kobetz-Kerman^{2,4}; Tulay Koru-Sengul^{2,4}; Erin N. Marcus³; Brendaly Rodriguez³; Yisel Alonso³; Orieta Fontan²; Valentine Cesar²; Olveen Carrasquillo^{1,4}. ¹University of Miami Miller School of Medicine, Miami, FL; ²Sylvester Comprehensive Cancer Center, Miami, FL; ³University of Miami Miller School of Medicine, Miami, FL; ⁴University of Miami Miller School of Medicine, Miami, FL. (*Tracking ID #1931851*)

BACKGROUND: Cervical cancer disproportionately impacts minority women. While screening substantially reduces cervical cancer mortality, many women in safety-net settings remain unscreened. System level barriers include limited resources and staffing. Patient barriers include financial (lack of insurance and co-payments), health literacy, and cultural norms. Provider barriers such as visit time constraints also exist. Human Papilloma Virus (HPV) self-sampling, in which women use a cotton swab device to self-collect material for an HPV assay, may be an attractive option in such settings.

METHODS: 1) To measure the acceptability and feasibility of HPV self-sampling among patients, we had two Community Health Workers (CHWs) recruit women from two clinics in Miami-Dade County. One site was a public hospital based clinic primarily serving Hispanics; the other a community based facility serving Haitians. CHWs identified women aged 30–65 years with no Pap smear in the past 3 years and gave a brief description of the study. We offered all eligible women the option of HPV self-sampling or discussing screening through Pap smears with their provider. If HPV self-sampling was selected, instructions on sampler use and assistance with collection was provided by the CHW. Patient attitudes towards HPV self-sampling were assessed using a 12-item survey modeled after existing surveys. Among women in whom the HPV self-sampler option was not chosen, the electronic medical record or paper chart were reviewed to assess if a Pap smear was performed. 2) To measure acceptability and feasibility among clinic staff (medical assistant, nurse, nurse practitioner, and physician), we developed a 9-item survey based on prior studies of provider screening acceptability. Through emails and personal invitations, staff were encouraged to participate in an anonymous online questionnaire.

RESULTS: Of 1725 women assessed, 62 % were not eligible due to having a Pap smear in the last 3 years. Of the 184 study eligible women, 91 % agreed to participate ($n=167$). Latinas represented 73 % and Haitians 27 % of the sample; 99 % were

uninsured. The HPV self-sampling approach was selected by 67 % of participants. The majority of participants agreed that HPV self-sampling was faster than the Pap smear (86 %), more private (93 %), and easy to use (97 %). Nearly all participants agreed they would use the self-sampler again (97 %) and recommend it to a friend or family member (96 %). Overall, 76 % of participants preferred the self-sampler to the Pap smear. High-risk HPV was detected in 11 % of samples. The CHW provided navigation to Pap smear for all women having high-risk HPV strains. Of those not selecting the self-sampler, 34 % had not yet had a Pap smear at 1 month post-recruitment. Of 178 clinic staff invited to participate in our survey, 16 % ($n=29$) completed the survey. Of those completing the survey, 69 % agreed it was difficult to perform a Pap smear because of time constraints and 79 % agreed they would be willing to incorporate HPV self-sampling into their practice.

CONCLUSIONS: HPV self-sampling was both feasible and highly acceptable in the safety-net clinics studied. A low response rate by clinic staff may limit the generalizability of the provider survey results. HPV self-sampling may be an important tool to address barriers to cervical cancer screening in resource limited settings.

ACCESS TO AND PREFERENCES FOR TEXT MESSAGING FOR MEDICAL AND INSURANCE REMINDERS IN A SAFETY NET POPULATION

Leah Zallman^{1,2}; Alex Harsha^{1,3}; Danny McCormick^{1,3}. ¹Cambridge Health Alliance, Cambridge, MA; ²Institute for Community Health, Cambridge, MA; ³Harvard Medical School, Boston, MA. (Tracking ID #1934972)

BACKGROUND: Text messaging has been used successfully to deliver health information interventions to underserved communities. Evidence suggests that text message reminders can increase patient appointment and treatment completion, and is a reliable method of communication even in communities with low literacy. Text messaging may offer similar opportunities to reach patients in health care safety net settings who are disproportionately impacted by homelessness or unstable housing, low health literacy and may be lost to follow up. The immediate, direct-to-patient nature of text messaging and the ability to send automated reminders at relatively low cost may help overcome communication barriers between healthcare providers and underserved communities in the US. While the opportunity to improve this communication may exist through text messaging, preferences for text messaging and patient characteristics associated with preferring text messages have not been elucidated.

METHODS: Between August and December 2013, we conducted a face-to-face verbally delivered survey regarding preferences for text messaging with 415 patients presenting to three emergency departments at a large integrated safety net health care system in the greater Boston area. We included patients aged 18–64, who had an Emergency Severity Index (ESI) of 2–5 (excluded most severely ill), had only one insurance type and spoke English, Portuguese, Spanish or Haitian Creole. We asked participants about their access to mobile phones with text messaging capability, preferences for receiving specific types of reminders by text (appointment, medication, and expiring insurance), and preferences for text messaging over other forms of communication. We used logistic regression models that controlled for age, gender, race/ethnicity, health insurance type and medical comorbidities to identify predictors of preferring text messages for medical reminders over other forms of communication with medical providers.

RESULTS: Overall, 96.5 % of participants reported having access to mobile phones with text messaging capability. Half reported a preference for text messaging over other forms of communication such as phone, mail or email. Respondents expressed preferences for appointment reminders (77 %), reminders regarding expiring insurance (55 %), and medication reminders (32 %). A minority (17 %) indicated that they preferred not to be text messaged by their healthcare provider. Reasons for not preferring text messaging included: cost of receiving text messages (11 %), privacy (17 %), not liking or understanding text messaging (40 %) and other (31 %). In logistic regression analyses, Hispanic ethnicity (1.68 [1.03–2.75]) and younger age (0.98 [0.96–1.00]) were associated with preferences for medication reminders. Similarly, Hispanic ethnicity (1.93 [1.09–3.43]) and younger age (0.98 [0.95–1.00]) were associated with preferences for expiring insurance reminders.

CONCLUSIONS: In a safety net population, the vast majority of patients have access to text messaging and a high proportion express preferences for text message reminders over other forms of communication. Reminders regarding appointments and expiring insurance were most highly desired. Text messaging may be a promising method to improve healthcare provider communication with underserved communities in the US.

ACCESS TO DEPRESSION CARE SERVICES: A NEEDS ASSESSMENT IN AN URBAN ACADEMIC PRIMARY CARE CLINIC

Lauren Peccoralo; Susan Truong. Mount Sinai Medical Center, New York, NY. (Tracking ID #1937528)

BACKGROUND: Major depressive and anxiety disorders are common and these and other psychiatric conditions are often encountered by primary care practitioners. Urban academic training centers serve patients at high risk for mental health disorders who often have little access to care, yet little is known about the perceived need for mental health services amongst primary care providers in these environments. The US Preventive Services Task Force endorses routine screening of all adults for depression in settings with adequate staff-assisted depression care support to provide appropriate care and follow up. The purpose of this survey was to assess the needs and barriers to depression care services amongst physician primary care providers in an urban academic training practice in the United States prior to the implementation of universal screening and a depression care program.

METHODS: From April through June 2013, we conducted an online survey about the perceptions of barriers to depression care and unmet psychiatric needs in the primary care practice in our clinic. Survey participants included primary care providers (all internal medicine residents and faculty providers) at the resident training clinic practice at the Mount Sinai School of Medicine in New York, New York. The survey was analyzed as descriptive data.

RESULTS: Ninety-two participants responded to the survey (74 resident trainees and 18 attending physicians, 62 % and 78 % response rate, respectively) during the study period. Eighty-three percent of residents and 88 % of attendings are currently caring for a patient(s) with depression. Eighty-six percent of residents and 100 % of attendings believe there are barriers to providing optimal care for patients with depression. The most commonly identified barriers to care are lack of psychiatrists (85 % residents, 94 % attendings), lack of coordination between primary care and psychiatry (83 % residents, 100 % attendings), and lack of patient education (54 % residents, 78 % attendings). Ninety-six percent of residents and 94 % of attendings have at least one patient with an unmet psychiatric need and 18 % of residents and 35 % of attendings have >10 patients with such a need. The most commonly cited psychiatric needs are depression (93 % residents, 100 % attendings), anxiety (74 % residents, 94 % attendings) and substance abuse (45 % residents, 47 % attendings).

CONCLUSIONS: Primary care providers at all levels perceive high need for and multiple barriers to depression and other mental health care. These data support the recommendation that appropriate mental health services should be available in tandem with the initiation of universal depression screening. Further research is needed to determine the impact of implementation of universal screening and depression care program in a primary care training environment.

ACCULTURATION AND MEASURES OF CARDIOVASCULAR RISK AMONG FILIPINA IMMIGRANTS

Jane Jih¹; Alka M. Kanaya¹; Maria Rosario G. Araneta². ¹UCSF, San Francisco, CA; ²UCSD, San Diego, CA. (Tracking ID #1938915)

BACKGROUND: Acculturation is a dynamic process that encompasses a broad spectrum of cultural changes, interactions and adaptations that affect health. In immigrant populations, acculturation has been associated with increased prevalence of obesity, diabetes and coronary heart disease (CHD). CHD and its risk factors are highly prevalent among Filipino Americans. However, limited studies have examined acculturation and CHD specifically among Filipino Americans. We used the University of California San Diego (UCSD) Filipino Women's Health Study to examine the relationship of acculturation and CHD and related risk factors among Filipina immigrants.

METHODS: The UCSD Filipino Women's Health Study is a longitudinal study of 453 Filipino American women ages 39–86 years recruited from 1995 to 1999 in which the prevalence of and risk factors for CHD, hypertension (HTN), diabetes and obesity was measured. In addition to collecting immigration data, an adapted acculturation scale with three domains [a] functional integration via language use; b) values on preserving culture; c) attitudes on family structure and sex-gender roles] was administered. Outcome variables included prevalence of CHD (defined by ECG, Rose questionnaire and history of myocardial infarction), HTN, diabetes and obesity. We examined several measures of acculturation including length of residence in the United States (US), proportion of life years in the US (years residing in US/age at enrollment) and each domain of the acculturation scale. We used logistic regression, adjusting for age, education and exercise, smoking, alcohol use and body mass index (BMI) for the CHD outcome, to estimate the association of each measure of acculturation to each outcome.

RESULTS: The mean age of Filipina immigrants ($n=446$) was 58 ± 9 years old. The mean length of US residence was 16 years (range 0–48). The prevalence of CHD was 21 %, HTN was 51 %, and type two diabetes was 33 %. Mean BMI was 25 ± 3 kg/m² and 23 % were obese as defined by the World Health Organization (WHO) Asian BMI scale (BMI ≥ 27.5 kg/m²). Measures of acculturation were not associated with CHD, HTN and diabetes outcomes. Length of residence in the US but not proportion of life years or the acculturation scale was associated with obesity defined by the WHO Asian BMI scale. For each additional year of living in the US, Filipina immigrants had a 21 % increase in the odds of obesity (adjusted odds ratio 1.21 (95 % CI 1.01–1.47)).

CONCLUSIONS: Filipina immigrants have a substantial burden of CHD and risk factors. Unlike other immigrant populations, acculturation to life in the US was not associated with CHD, HTN and diabetes prevalence in Filipino women. However, longer duration of residence in the US was associated with increased odds of obesity. Exposure to a westernized lifestyle during the Spanish and US colonization in the Philippines may mitigate the impact of migration on cardiovascular health among Filipina immigrants.

ACCURACY AND GAMING OF THE ACUTE BRONCHITIS ANTIBIOTIC PRESCRIBING PERFORMANCE MEASURE Patrick P. Dempsey¹; Harry Reyes Nieva¹; Alexandra C. Businger¹; Jeffrey A. Linder^{1,2}. ¹Brigham and Womens Hospital, Boston, MA; ²Harvard Medical School, Boston, MA. (Tracking ID #1938252)

BACKGROUND: Acute bronchitis is a cough-predominant illness of less than 3 weeks duration in a patient without chronic lung disease. A national performance measure states that antibiotics are not indicated for acute bronchitis. However, concerns have been raised about the measure's accuracy and susceptibility to gaming. We compared the performance measure to chart review to assess the accuracy of the performance measure and detect gaming.

METHODS: We assessed 57,766 visits to an academic primary care practice between May 2011 and September 2012. For the chart review, we included patients aged 18–64 and excluded patients with chronic lung disease on the problem list or who made a study clinic visit in the prior 30 days ($n=26,539$). Two trained chart abstractors reviewed these notes and coded whether the treating clinician diagnosed the patient with acute bronchitis. We calculated a modified Healthcare Effectiveness Data and Information Set (HEDIS) performance measure by including patients aged 18–64 with ICD-9 diagnosis codes of 466 or 490, excluding patients with chronic lung disease, immunosuppression, and cancer. Using chart review as the gold standard, we calculated the sensitivity, specificity, and positive predictive value of the acute bronchitis performance measure.

RESULTS: There were 31,174 visits which neither the performance measure nor chart review identified as an acute bronchitis visit. According to the performance measure, there were 90 acute bronchitis visits (88 with a diagnosis code of 466 and 2 with a diagnosis code of 490). There were 143 visits identified as acute bronchitis visits by both the performance measure and chart review ($n=41$; “true positives”), the performance measure only ($n=49$; “false positives”), or chart review only ($n=53$; “false negatives”). These patients had a mean age of 48 years old; 77 % women; and 44 % white, 28 % Black, and 17 % Latino. Compared to chart review, the performance measure had a positive predictive value of 46 %, a sensitivity of 44 % and a specificity of >99 %. Of the 49 “false positives,” according to the chart, 10 visits were for other ARIs, seven visits were to other practices, seven the patient had been coughing for more than 3 weeks, five the patient did not have cough, five the patient had chronic lung disease, and 15 the patient had a visit in the prior 30 days. Of the 53 “false negatives”—for which the clinician diagnosed the patient with acute bronchitis in their note—52 did not have an acute bronchitis diagnosis code (most common diagnosis codes were cough, hypertension, upper respiratory infection, and viral infection) and one had a diagnosis code of asthma that was not mentioned in the chart. The antibiotic prescribing rate for true positives was 22 %, for false positives was 4 %, and false negatives was 30 %.

CONCLUSIONS: Compared to chart review, the acute bronchitis performance measure has a sensitivity and positive predictive value of less than 50 %. The performance measure omitted visits with antibiotic prescribing and falsely included visits without antibiotic prescribing, suggesting gaming.

ADAPTIVE RESERVE AT COMMUNITY HEALTH CENTERS: THE CANCER PREVENTION AND CONTROL RESEARCH NETWORK (CPCRN) MULTI-STATE SURVEY Shin-Ping Tu^{1,2}; Alan Kuniyuki²; Vicki M. Young³; Maria Fernandez⁴; Rebecca S. Williams⁵; Amanda Kimura². ¹Virginia Common-

wealth University, Richmond, VA; ²University of Washington, Seattle, WA; ³South Carolina Primary Healthcare Association, Columbia, SC; ⁴University of Texas at Houston, Houston, TX; ⁵UNC Chapel Hill, Chapel Hill, NC. (Tracking ID #1936531)

BACKGROUND: Adaptive Reserve comprises intangible elements of a practice's capacity (i.e., human relationships, teamwork, a learning culture) that provides flexibility, resilience, and enhance positive change. Our objective is to determine the Adaptive Reserve at Community Health Centers (CHCs) in seven states (California, Colorado, Georgia, Missouri, South Carolina, Texas, and Washington).

METHODS: We selected the Patient Centered Medical Home (PCMH) and the Consolidated Framework for Implementation Research to guide this research. Our survey included questions on colorectal cancer screening PCMH best practices and items from the Clinician Staff Questionnaire to examine the practice Adaptive Reserve (PAR) of participating CHC clinics. PAR scores were scaled from 0.00 to 1.00, with higher scores representing greater Adaptive Reserve. In collaboration with Primary Care Associations and CHCs, we recruited a convenience sample of 76 CHC clinics and invited their clinical staff (providers, nurses, and medical assistants) to participate in our CPCRN Community Health Center Survey.

RESULTS: Survey respondents ($N=246$) are mostly female (82 %) and non-Hispanic (61 %). Forty-two percent reported their clinic had 7–8 colorectal cancer (CRC) screening PCMH best practices (maximum 8). Preliminary PAR scores in the states ranged from 0.61 to 0.7. In a study on PCMH implementation, 36 practices expected to have significant capability for change had a mean baseline PAR score of 0.69. Our survey indicates higher levels of PAR to be positively associated with CRC screening best practices in the clinics (adjusted OR=3.62; 95 % CI 1.31, 10.02) and how frequently staff performed the best practices ($p=0.005$).

CONCLUSIONS: Evidence from primary care transformation indicates that practices with strong Adaptive Reserve are more successful at incorporating change. With the Affordable Care Act, understanding the Adaptive Reserve of CHC clinics will be timely for the many changes needed to successfully expand primary care at CHCs.

ADVANCE DIRECTIVE INTERVENTION FOR CHRONICALLY HOMELESS PEOPLE: ACCEPTABILITY, FACTORS ASSOCIATED WITH COMPLETION, AND TREATMENT PREFERENCES Alexander Leung¹; Dhruv Nayyar¹; Manisha Sachdeva¹; John Song²; Stephen Hwang¹. ¹St. Michael, Toronto, ON, Canada; ²University of Minnesota, Minneapolis, MN. (Tracking ID #1933803)

BACKGROUND: End-of-life care planning is relevant for homeless individuals because they experience high morbidity and mortality. A previous study has shown that homeless persons are more likely to complete advance directives with a one-on-one counselor-guided intervention than if the advance directive is self-completed. However, the acceptability of a counselor-guided intervention for the completion of advance directives among chronically homeless individuals has not been investigated. The aim of this study was to determine the acceptability of a counselor-guided intervention for the completion of advance directives among chronically homeless individuals. Secondary objectives were to identify characteristics associated with willingness to complete an advance directive and to characterize treatment preferences in this population.

METHODS: In a single-group intervention study, homeless men residing at a shelter in Toronto, Ontario were recruited from April to June 2013. Recruitment took place among programs that served chronically homeless individuals who were residents in a managed alcohol harm reduction program, a medical respite program that treats individuals with acute or uncontrolled chronic illnesses, and a long-term program for individuals who have been homeless for extended periods of time. Two hundred five homeless men (89.1 % of those approached) participated in the study. Participants completed a survey which obtained information on potential predictors of advance directive completion, including socio-demographic characteristics, health status, health care use, and attitudes towards end-of-life care and death. After completing this survey, all participants were offered an opportunity to complete an advance directive with a trained counselor. The primary outcome was the proportion of participants who completed an advance directive. The characteristics associated with completion of an advance directive were examined.

RESULTS: The duration of homelessness was 12 months or longer in 72.8 % of participants. A total of 103 participants (50.2 %) completed an advance directive. Socio-demographic characteristics, health status, and health care use were not associated with completion of an advance directive. Participants were significantly more likely to complete an advance directive if they reported thinking about death on a daily basis, believed that thinking about their friends and family was important, or reported knowing their wishes for end-of-life care but not having told anyone about

these wishes. Of 103 individuals who completed an advance directive, the proportion expressing a preference to receive cardiopulmonary resuscitation in the event of a cardiorespiratory arrest was 94.1 %, 81.3 %, 64.7 %, and 36.3 % if there was a chance of returning to their current state of health or hypothetical health states of moderate dementia, severe dementia, and permanent coma, respectively.

CONCLUSIONS: As the homeless population continues to age, health care professionals will encounter an increase in chronically homeless persons facing complex end-of-life care needs. A single-encounter, one-on-one counselor-guided intervention can achieve a high rate of advance directive completion among chronically homeless individuals. Health care providers should initiate advance care planning discussions with their patients who are homeless. Future research aims to ascertain whether the completion of an advance directive has an effect on subsequent care in homeless individuals.

ADVANCED DIRECTIVE USE IN INTERNAL MEDICINE RESIDENCY CLINICS: A RETROSPECTIVE REVIEW Briana N. Ketterer; Corinne Self; Guadalupe Martinez; Jennifer Gabbard; Macy Whitley; Ellyn Lee. University of Arizona, Tucson, AZ. (Tracking ID #1923316)

BACKGROUND: Advanced directives (AD) allow patients to voice preferences about life sustaining therapies and end-of-life (EOL) care. ADs improve satisfaction, reduce stress, anxiety and depression at EOL. However, this information needs to be discussed and documented to be effective. Resident physicians play a key role as one of the first providers to encounter patients thus, making them an integral hub in the health delivery system. We sought to evaluate Internal Medicine (IM) Residents' practice habits and assess participation in EOL/AD planning, and documentation of those preferences. This information will serve to address potential weaknesses in the Residency curricula and areas for improvement.

METHODS: Retrospective chart review of patients seen in IM Residency clinics at The University of Arizona Medical Center (UAMC) from July 2011–2013. Inclusion criteria: ≥65 years of age with at least one chronic, debilitating diagnosis associated with morbidity or mortality (dementia, AIDS, cancer, neurodegenerative disease, chronic obstructive pulmonary disease, chronic kidney disease, cerebral vascular accident or transient ischemic attack, liver cirrhosis, coronary artery disease or myocardial infarction, post-transplant) documented in the electronic medical record, AllScripts. Documentation was reviewed and ADs were recorded along with demographics (age, gender), number and type of diagnoses.

RESULTS: Reviewed 1075 charts, 165 met inclusion criteria (M 47 %, F 53 %; average age, 75; average number of problems, 7) with most frequent diagnoses of: cardiovascular disease (52 %), cancer (34 %), CKD (17 %). AD documented in 17 of 165 charts (10 %) which included: AD discussion (2), no specific qualifiers (1), Medical Power Of Attorney (8), DNR/DNI (9), Living Will (4), Hospice (1), and documentation for first responders (4).

CONCLUSIONS: IM Residents at UAMC clinics documented ADs in a mere 10 % of seemingly tenuous patients ≥65 years of age. This represents a cohort who would benefit from AD conversations to preserve their wishes at EOL. Although residents have some training in EOL care and AD, the curricula appears insufficient as the rate of AD documentation is very low and residents feel uncomfortable with those discussions as unpublished data from our group similarly suggests. One way to improve upon this is to implement an educational intervention to enhance training, improve AD discussions, and address all AD components with patients. Improvement in this area is crucial as it would not only fulfill residency competency requirements but also lead to more complete ADs allowing patients greater autonomy in their EOL care.

AGING WITH HIV: SYMPTOM BURDEN AND IMPACT ON QUALITY OF LIFE Meredith Greene^{1,2}; Christine Ritchie¹; Jeff Martin⁴; Joy A. Madamba³; Monica Mattes⁵; Yinghui Miao²; Steven Deeks³; Victor Valcour^{1,6}. ¹University of California San Francisco, San Francisco, CA; ²San Francisco VA Medical Center, San Francisco, CA; ³University of California San Francisco, San Francisco, CA; ⁴University of California San Francisco, San Francisco, CA; ⁵University of Central Florida College of Medicine, Orlando, FL; ⁶University of California San Francisco, San Francisco, CA. (Tracking ID #1932204)

BACKGROUND: As HIV infection has shifted from a life-threatening disease to a chronic illness, the HIV-infected population is aging and often facing multiple comorbid conditions. Symptom assessment is an important clinical tool in the management of patients with complex chronic disease, yet limited data exists about symptom burden in older HIV-infected adults especially in the modern treatment era.

The primary aim of this study was to describe the symptom burden (frequency and severity of symptoms) among HIV-infected adults over age 50 on combination antiretroviral therapy. We also examined factors associated with symptom burden in this population and the association of symptom burden on health related quality of life.

METHODS: We conducted a cross-sectional survey in 2012–2013 of HIV-infected adults over age 50 that had an undetectable viral load (HIV RNA) on antiretroviral therapy and were enrolled in a clinic based cohort at a county medical center in San Francisco. Sixteen symptoms were measured by self-report in a two part question based on the 12 item HIV symptom index: 1) yes/no for presence of each symptom in the past week and 2) degree of severity of each symptom (not a problem, mild, moderate, severe, very severe) as judged by symptom frequency, intensity, and duration. Symptom severity was analyzed by examining the number of symptoms rated as moderate, severe, or very severe. Health related quality of life was assessed by a single-item self-report of health as excellent, very good, good, fair or poor. Demographics, HIV related factors, co-morbidities and medications were measured by self-report and verified by chart review. Descriptive statistics were used for data analysis.

RESULTS: 142 participants were enrolled, of which 94 % were male, 63 % were Caucasian, with a median age of 57 (range 50–74). The median CD4 count was 576 (IQR 393–715) and the median length of HIV infection was 22 (IQR 18–25) years. Participants had a median of 4 (IQR 3–6) co-morbid conditions, most commonly hyperlipidemia (61.3 %) and hypertension (52.8 %) and were taking a median of 9 (IQR 5–12) non-antiretroviral medications. Sixty-nine percent of participants reported two or more symptoms, with a median of 3 (IQR 1–5) symptoms reported. Fatigue ($n=72$, 51 %), "feeling sad or depressed" ($n=60$, 42 %), "pain, tingling, loss of feeling in feet or hands" ($n=54$, 38 %) and insomnia ($n=53$, 37 %) were the most commonly reported symptoms. Fifty-five percent of participants reported at least one moderate to very severe symptom with a median of 1 (IQR 0–2) moderate to very severe symptom reported. Fatigue ($n=31$, 22 %), "feeling sad" ($n=31$, 22 %) and insomnia ($n=25$, 18 %) were the most frequent severe symptoms. The total number of co-morbid conditions was associated with both the total number of symptoms reported ($r_s=0.21$, $p=0.01$) and symptom severity ($r_s=0.27$, $p<0.001$) and the total number of non-antiretroviral medications was associated with symptom severity ($r_s=0.21$, $p=0.01$). HIV related factors such as CD4 count and length of HIV infection did not have statistically significant correlations with symptom frequency or severity. Both the total number of symptoms and symptom severity were inversely correlated with overall health related quality of life ($r_s=-0.42$, $p<0.001$; $r_s=-0.47$, $p<0.001$).

CONCLUSIONS: Among adults age 50 and older with well-controlled HIV-infection, symptom burden was substantial and associated at least in part with co-morbid conditions. Addressing symptom burden during routine clinical encounters merits attention and may improve quality of life as the HIV-infected population ages.

ALLOWING PATIENT CHOICE BETWEEN TWO DIVERSE DIETS DID NOT IMPROVE WEIGHT LOSS William S. Yancy^{1,2}; Cynthia Coffman^{1,3}; Valerie Smith¹; Stephanie B. Mayer⁴; Ronette L. Kolotkin⁵; Paula J. Geiselman⁵; Megan McVay¹; Eugene Z. Oddone^{1,2}; Corrine Voils^{1,2}. ¹VAMC, Durham, NC; ²Duke University, Durham, NC; ³Duke University, Durham, NC; ⁴Virginia Commonwealth University, Richmond, VA; ⁵Louisiana State University, Baton Rouge, LA; ⁶Quality of Life Consulting, Durham, NC. (Tracking ID #1941417)

BACKGROUND: A variety of diet approaches lead to modest weight loss, and dietary adherence is a strong predictor of success. Allowing individuals to choose diet composition after considering their food preferences may improve adherence by increasing autonomy and self-efficacy. In a randomized trial, we examined whether participants who chose a diet experienced greater weight loss than those randomly assigned a diet.

METHODS: Participants were Durham Veterans Affairs Medical Center outpatients aged <75 years with body mass index (BMI) ≥ 30 kg/m² and no unstable health problems. They were randomized to the Control or Choice arm, stratified by sex, BMI < or ≥ 40 kg/m², and presence of type two diabetes. Control participants were randomly assigned to follow a low-carbohydrate (LCD) or a low-fat/reduced-calorie (LFD) diet. Choice participants were presented individual results from the Geiselman Food Preference Questionnaire, indicating which diet fit their food preferences best, as well as information about the two diets; 1 week later, they were called to elicit their diet choice. All participants then received diet counseling led by a dietitian in groups of 8–19 participants separated by arm and diet approach. In-person group sessions occurred every 2 weeks for 24 weeks, then every 4 weeks for 24 weeks interspersed with one-on-one telephone sessions mid-month from the dietitian focusing on behavioral goal-setting. All participants received literature specific to their diet; a

pocket calorie/carbohydrate/fat counting guide; and a recommendation to exercise 150 min per week. At week 12, Choice participants could switch to the other diet if dissatisfied with their initial diet choice. The primary outcome, weight, was measured on a digital scale at the 19 visits in light clothing and no shoes. Secondary outcomes measured every 12 weeks were dietary intake by Block food frequency questionnaire and the Impact of Weight on Quality of Life-Lite (IWQOL-Lite) questionnaire (scale 0–100; higher score indicates higher quality of life). Linear mixed models were fit for these continuous outcomes, and included a common intercept, time effect, time*treatment interaction, randomization stratification variables and random effect to account for group clustering.

RESULTS: A total of 207 participants were enrolled. Mean age was 54 years, 27 % were women, 51 % were White, 43 % were Black, 22 % had diabetes. Mean weight at baseline was 109 kg and mean BMI 36 kg/m². In the Choice arm, 61 (58 %) chose the LCD and 44 (42 %) chose the LFD; only three LCD and two LFD participants switched diets at 12 weeks. Final measurements were collected in 88 of 102 (86 %) in the Control arm and 87 of 105 (83 %) in the Choice arm. Mean weight loss at 48 weeks was -5.3 % in Control participants and -4.2 % in Choice participants (difference 1.1 %, 95 % CI 0.0 to 2.2, $p=0.06$). Dietary adherence was similar in the Control and Choice arms, with mean percent deviation from macronutrient goal differing by 0.6 % (10.1 % vs 10.7 %, respectively) at week 48. Mean IWQOL-Lite total scores were similar at week 48 (Control 82.9, Choice 81.7, difference -1.3, 95 % CI -4.5 to 2.0).

CONCLUSIONS: Educating patients on diet approaches and their food preferences, and then allowing them to choose their diet composition, did not result in greater weight loss compared to random diet assignment. Future research could consider targeting diet to individuals based on metabolic, genetic or other characteristics that might predict improved outcomes.

AN ACHILLES HEEL OF DISPARITIES RESEARCH: MISSING RACIAL DATA IN A STUDY OF MORTALITY AFTER CRITICAL ILLNESS

Mallika Mundkur^{1,2}; Swapna Abhyankar¹; Fiona M. Callaghan¹; Clement J. McDonald¹.

¹National Institutes of Health, Bethesda, MD; ²George Washington University, Washington, DC. (*Tracking ID #1936298*)

BACKGROUND: Research has consistently demonstrated the presence of racial disparities in care and outcomes across inpatient and outpatient settings. However, studies focused on disparities in the intensive care unit (ICU) have yielded conflicting results, albeit with considerable variation in design and case-mix. Some analyses of ICU outcomes have detected greater mortality for minorities as compared to non-minority populations for conditions such as severe sepsis or trauma (Mayr et al., 2010; Haider et al., 2007), while others have found lower mortality rates for minorities with conditions such as community-acquired pneumonia (Frei et al., 2010). Recently, a retrospective study of 9518 patients in California concluded that in-hospital all-cause mortality for ICU patients was equivalent across race categories after adjusting for socioeconomic status, resuscitation preferences and severity of illness (Erickson et al., 2011). In the study by Erickson et al., patients without known race, equivalent to 10 % of overall study population, were excluded from the analysis—potentially biasing results, but noted to be common practice among other studies of racial disparities (Long, Bamba, Ling, Shea, 2006). We designed our study not only to contribute to the unresolved discourse on disparities in the ICU but also to ensure that patients with missing race would be examined.

METHODS: We performed a retrospective cohort study utilizing the Multiparameter Intelligence Monitoring in Intensive Care (MIMIC-II) research database (Saeed et al., 2011; Lee et al., 2011). MIMIC-II contains de-identified clinical information on 32,425 adult and neonatal ICU patients admitted to Beth Israel Deaconess Hospital in Boston, MA between 2001 and 2008. Our cohort was comprised of adult patients (age >18) admitted to a medical or surgical ICU for at least 4 h for a non-elective admission. For patients with multiple ICU admissions, only the first stay was included. Our primary outcome was 30-day all-cause mortality. Covariates were: race, age, gender, marital status, type of insurance coverage (indicator of socioeconomic status), code status within 2 h of ICU admission, Simplified Acute Physiology Score (SAPS) (severity of illness indicator), admission source (e.g., emergency room vs. transfer) and comorbidities including congestive heart failure, chronic renal failure/end-stage renal disease, chronic liver disease, and cancer. We used demographic data to group patients into the following race categories: White, Black, Hispanic, Asian/Pacific Islander, Other and included an Unknown category for patients without documented race. We used the software package R for all statistical analysis. We used Kruskal-Wallis, Pearson's chi-squared, and Fisher's exact tests to assess the

unadjusted associations between race and the covariates, log-rank test to detect differences in survival curves, and multivariable logistic regression for our main analysis.

RESULTS: 13,491 patients met our inclusion criteria and crude mortality rates for the race categories ($p<0.0001$) were as follows: 17.6 % for the total population, 17.6 % for the White group, 13.6 % for the Asian group, 6.7 % for the Hispanic group, 14.7 % for the Other category, and 28 % for the Unknown group. Odds ratios for our primary outcome of 30-day mortality are summarized in Table 1. For the Unknown group, 40.2 % of the patients were transfers as compared to 14.6 % for the overall study population ($p<0.0001$).

CONCLUSIONS: We were surprised by the finding that all-cause mortality at 30 days was substantially higher for patients with unknown race than for any of the other race categories. Aside from the White group, the unknown group was larger than any of the other race categories. Thus, while the White group appeared to have the greatest mortality among the known race groups, if the unknown group were predominantly Black, Hispanic or another race, the results could have been different. For the Unknown category, we observed a disproportionate number of transfers from other hospitals. Our findings generate questions for those researching healthcare disparities, including why race is unknown for many patients and whether this group is at higher risk of other adverse outcomes. Efforts should be made to include these patients in analyses and reduce the number of patients without documented race to improve our ability to accurately examine and eliminate healthcare disparities.

Table 1. Risk for 30-day Mortality by race based on adjusted multivariable logistic regression

Race Category	n	30-day mortality risk OR (95 % CI)	p-value
White (reference group)	9523	1.00	n/a
Black	1244	0.66 (0.53, 0.82)	0.0002
Asian	331	0.56 (0.39, 0.81)	0.0019
Hispanic	489	0.53 (0.36, 0.78)	0.0014
Other	307	1.06 (0.73, 1.55)	0.75
Unknown	1594	1.96 (1.67, 2.29)	<0.0001

AN EVALUATION OF “CLINICALLY PROVEN” DIETARY SUPPLEMENTS

Alysha Melnyk; Bimal Ashar; April S. Fitzgerald. Johns Hopkins University, Baltimore, MD. (*Tracking ID #1939374*)

BACKGROUND: The Dietary Supplement Health and Education Act (DSHEA) permits manufacturers to sell products without providing pre-market evidence of safety or efficacy. One fundamental reason for the passage of the DSHEA was to empower consumers to make their own choices. Yet, data suggests that the public is unaware of the limited regulation on product marketing and advertising. Dietary supplements are frequently advertised as being “clinically proven.” Yet, there are not standards in place to determine acceptable use of this term. This study was undertaken to evaluate products that have been advertised as being “clinically proven” in order to determine the availability of data used to make such an assertion.

METHODS: An internet survey for products was performed by using the search terms “clinically proven dietary supplements”, “dietary supplements”, “best dietary supplements” in common search engines. Advertisements were then reviewed to see if they contained terms that suggested definitive efficacy. Products whose advertisements contained terms such as “clinically proven”, “scientifically proven”, “clinically supported” were included in the study. Products returned via the search were then categorized for what they were purported to be proven to do. Additionally, the supplement advertisements were analyzed to determine if evidence was readily available to consumers that would support the “clinically proven” label. If evidence supporting the statement was not readily available on their website, companies were contacted to attempt to obtain any information supporting their claim. Descriptive statistics were used to categorize products and determine what percentage of such products had available references to studies supporting their claims.

RESULTS: A total of 99 dietary supplements were found that referenced definitive scientific efficacy. Most of these products (63 %) were advertised as being useful for helping consumers lose weight and/or build muscle. Despite the assertion for efficacy, only 28 made direct reference on their website to any scientific studies. After being contacted, an additional eight companies provided studies and/or links to evidence. The remaining companies (64 %) either had no testing to report (21 %), claimed that they had testing but would not provide it (4 %), claimed that their evidence was all on

their website (13 %), did not respond to inquiries (14 %), or had no listed contact information on their internet advertisement (11 %).

CONCLUSIONS: A number of dietary supplements are advertised as being clinically or scientifically proven, yet provide little to no evidence to consumers to substantiate their claims. Truth-in-advertising standards for dietary supplements should define parameters for using such terminology in order to protect the public from potentially misleading claims.

AN EVALUATION OF COMPUTERIZED DRUG-DRUG INTERACTION ALERT OVERRIDES IN AMBULATORY CARE Sarah P. Slight^{1,2}; Diane L. Seger³; Karen C. Nanji^{4,5}; Insook Cho^{1,6}; Nivethitha Maniam³; Patricia C. Dkyes^{1,4}; David W. Bates^{1,4}. ¹Brigham and Women's Hospital, Boston, MA; ²Durham University, Stockton on Tees, United Kingdom; ³Partners Healthcare Systems, Inc., Boston, MA; ⁴Harvard Medical School, Boston, MA; ⁵Massachusetts General Hospital, Boston, MA; ⁶Inha University, Incheon, MA. (*Tracking ID #1935807*)

BACKGROUND: Computerized physician order entry with clinical decision support (CDS) represents a valuable tool for improving medication safety, quality, and efficiency. CDS systems can provide health care providers with real-time, relevant, patient-specific information and alert them to potential prescribing errors. Providers may choose to override these alerts however, selecting a coded reason in order to proceed with the medication order. It is often unclear whether these particular actions, e.g., will monitor drug levels as recommended, are carried out by the provider or just simply ignored. We evaluated why providers overrode drug-drug interaction (DDI) alerts and what actions they took as a consequence of the alert.

METHODS: This study was a cross-sectional, observational study of DDI alerts generated over a three-year period between January 2009 and December 2011. All Level 2 DDI alert overrides were downloaded with IRB approval from 36 primary care practices affiliated with two Harvard teaching hospitals (total 14,966 overrides, 60.2 % of alerts generated). Any duplicates were removed and replaced. A physician and pharmacist expert panel assessed the appropriateness of these DDI alert overrides. A detailed chart review was conducted for each of the appropriate overrides to ascertain whether the provider had carried out their intended action(s).

RESULTS: Providers appropriately overrode just over two-thirds (338/496) of the DDI alerts and carried out the intended action in less than two-thirds (214/338) of these cases. Eight drugs were responsible for generating approximately three quarters of these alerts. The most common coded reasons for overriding DDI alerts were 'will monitor as recommended' (43.9 %, n=218), 'will adjust dose as recommended' (16.9 %, n=84), and 'patient has already tolerated combination' (15.7 %, n=78). Of the 121 appropriate alert overrides where the provider said they would 'monitor as recommended', only 35.5 % (n=43) actually completed the monitoring. Our study also revealed how only 60 % (n=21) of providers who indicated that they would 'adjust the dose as recommended' actually did. Furthermore, some providers selected the coded reason 'patient has already tolerated combination', yet no information was found to suggest that the patient had been taking both drugs together previously.

CONCLUSIONS: We found that providers continue to override important and useful alerts, some of which likely cause serious patient injuries, although we did not measure injuries in this study. A key difference between our study and previous studies¹ is that we also reviewed the charts to see whether the provider actually took action as a consequence of the alert. We found that the intended action was carried out in only two-thirds of cases. More research is needed to explore the human factors elements that influence provider behaviour, such as patient demands, workload, and time constraints. References: 1. BACKGROUND: While evidence suggests that computerized decision support (CDS) increases safety and quality of care, understanding how physicians respond to CDS alerts is a critical factor in achieving meaningful use of electronic health records. We continue to observe a high level of medication alert overrides for many prescription domains. While some overrides are justified clinically, others are not, and it is important to be able to reach out to those providers who are not prescribing optimally and understand their reasons for overriding alerts.

METHODS: All Level 2 alert overrides that required a coded reason to be provided at the time of prescribing were downloaded between January 2009 and December 2011 in the outpatient primary care setting. We limited our sample to providers who had received 20 or more alerts in each of the prescribing domains (drug-drug interaction, drug-allergy interaction, renal suggestion, age-based, duplicate-drug, and formulary substitution alerts) and the number of times each provider overrode these alerts was calculated. Of the 725 providers eligible, those with a high inappropriate override rate (above 75 % within a specific domain or overall) were targeted for interviews. The sessions were tailored to each provider's overrides and conducted by a research pharmacist or physician trained in counter-detailing techniques. Graphical material, including performance level data, a list of their inappropriate overrides and supporting evidence-based summaries, was presented to each provider during the discussion. An analysis of the data was carried out and prevalent concepts related to general views on alert functionality and specific prescribing behavior identified.

RESULTS: We conducted 23 interview sessions across primary care clinics affiliated with Brigham and Women's Hospital and Massachusetts General Hospital. We identified seven high level content categories: clinical satisfaction, clinical utility and relevance, variant user knowledge, impact on clinician reviewing process, patient preferences, current alerting tool challenges, and considerations for the future. Overall, providers were favorable towards the alerts and found them helpful in identifying possible adverse interactions. Many providers, however, found that the clinical relevance of the alerts could be improved by including magnitude of risk, suggested alternate treatments, recent laboratory values, and more up-to-date reference material. Additionally, many participants said they failed to provide a valid override reason because they found the alerts time-consuming and disruptive. Limitations of the existing EHR infrastructure such as inaccurate medication and allergy lists were identified as contributing to unnecessary alerts. Creating a more patient specific alerting tool was recognized as a future area of focus.

CONCLUSIONS: Many providers were unaware of their relatively high rate of overriding and this study allowed providers the unique opportunity of objectively assessing their prescribing behavior. Key issues that emerged from the sessions included the perceived risk to physician autonomy in decision-making, the increase of clinically irrelevant alerts leading to alert fatigue, and the lack of supplementary clinical information. By incorporating provider preferences, customizing alerts to the context of the visit, and offering additional clinical data, providers felt that CDS alerts would be less likely to be overridden providing more effective, efficient, and equitable care.

AN INTERNATIONAL EVALUATION OF DRUG-DRUG INTERACTION ALERTS THAT SHOULD BE NON-INTERRUPTIVE IN U.K. AND U.S. Alexandra Robertson¹; Sarah P. Slight^{1,2}; Diane L. Seger³; Sarah K. Thomas⁴; Jamie Coleman⁴; David W. Bates^{1,5}; Shobha Phansalkar^{1,6}. ¹Brigham and Women's Hospital, Boston, MA; ²The University of Durham, Durham, United Kingdom; ³Partners HealthCare Systems, Inc., Wellesley, MA; ⁴The University of Birmingham, Birmingham, United Kingdom; ⁵Harvard Medical School, Boston, MA; ⁶Wolters Kluwer Health, Indianapolis, IN. (*Tracking ID #1937914*)

BACKGROUND: Clinical Decision Support (CDS) has the potential to improve patient safety by providing knowledge and support at the point of prescribing. CDS systems can, however, deliver an overdose of alerts that may result in "alert fatigue," with providers overlooking clinically significant alerts as well as those considered less critical. In a previous study, Phansalkar et. al. (2012), identified 33 non-critical drug-class and class-class interaction alerts that could

be safely made non-interruptive with a goal to reduce alert fatigue. This study aims to establish whether these non-critical drug-drug interaction (DDI) alerts were set as interruptive or non-interruptive in U.K. and U.S. systems, and the rate at which these alerts were generated and overridden.

METHODS: With the necessary ethical approvals, we downloaded all low priority drug-class and class-class DDI alerts generated from January 2009 to December 2011 in three home-grown electronic health records (EHRs) at two academic medical centers: one British inpatient system and one U.S. inpatient and one outpatient system. We defined interruptive alerts as those requiring a provider response or action when generated and non-interruptive alerts as those that did not require a provider response. In the U.K. system we downloaded all level 3 inpatient alerts, which require a box to be ticked to acknowledge receipt of the alert. No override reasons are collected by this system. In the U.S. systems we downloaded all level 2 alerts, which require a coded reason to be provided at the point of prescribing. The number of alerts generated and overridden were downloaded for all three systems. Using this data, we calculated the frequency of alerts generated and override rates for all low priority DDI alerts.

RESULTS: In the U.S. system, 2 of the 33 low-priority drug-class and class-class interactions were set as interruptive; these included niacin and statins, and proton pump inhibitors and imidazoles. These drug-drug combinations triggered a total of 301 alerts in the U.S. outpatient and inpatient systems, which were overridden in 77.7 % of cases ($n=234$) during the period assessed. The niacin and statin interaction was triggered most often in both the U.S. inpatient ($n=62$) and outpatient ($n=215$) systems, and overridden 90.3 % of the time in the inpatient system ($n=56$) and 70.2 % in the outpatient system ($n=151$). In the U.K. system, 8 of the 33 low priority drug-class and class-class interactions identified were set as interruptive and triggered a total of 2,354 interruptive alerts, which were overridden in 63.5 % of cases ($n=1,495$). The most common were: ACE inhibitors and angiotensin II receptor antagonists; anticoagulants and corticosteroids; NSAIDs and β -adrenergic blockers; thiazide-type diuretics and NSAIDs; ACE inhibitors and NSAIDs; and sulfonylureas and ACE inhibitors, with the latter two pairs overridden most often. Sulfonylureas and ACE inhibitors triggered 42.6 % of all class-class alerts ($n=1,002$) and were overridden in 63.4 % of cases ($n=645$). Of the sulfonylureas and ACE inhibitors, the glipizide/gliclazide MR and perindopril alerts accounted for almost half of this class-class category (55.4 %, $n=556$) and were overridden in 69.9 % ($n=387$) of cases. ACE inhibitors and NSAIDs occurred second most often (22.3 %, $n=525$) in the U.K. system, with an 87.4 % override rate ($n=459$). Within this class-class category, ramipril and ibuprofen accounted for more than half (52.4 %, $n=275$) and were overridden in 90.1 % of cases ($n=248$).

CONCLUSIONS: Our team has previously shown that certain non-critical alerts may be safely made non-interruptive in provider workflows. This study offers assessment of the non-critical alerts previously identified to better understand user response to these alerts. Given the high rates of override amongst those reviewed, we feel this work offers further validation that these alerts may be safely made non-interruptive to minimize alert fatigue and support the patient safety aims of CDS.

AN INTERNATIONAL EVALUATION OF USER PERCEPTIONS OF DRUG-DRUG AND DRUG-ALLERGY INTERACTION ALERTS Alexandra Robertson¹; Pamela M. Neri²; Elisabeth Burdick¹; Sarah P. Slight^{1,3}; David W. Bates^{1,4}; Shobha Phansalkar^{1,5}. ¹Brigham and Women's Hospital, Boston, MA; ²Partners HealthCare Systems, Inc., Wellesley, MA; ³The University of Durham, Durham, United Kingdom; ⁴Harvard Medical School, Boston, MA; ⁵Wolters Kluwer Health, Indianapolis, IN. (Tracking ID #1938373)

BACKGROUND: Electronic medical records (EMR) with integrated clinical decision support (CDS) have the potential to improve patient safety. Increasing adoption, refining the delivery and content of existing CDS, and improving user-centered design are key to meeting core measures for Meaningful Use of EMRs. Override rates of CDS alerts are estimated to be between 49 and 96 %. Limited evidence supports a direct link between the availability of CDS to measurable improvements in patient safety. Among several reasons, poor user acceptance of alerts is widely recognized as a major barrier to realizing the potential impacts of CDS systems on patient safety. Poor alert design and lack of contextual specificity are causes for negative user perceptions about the utility of CDS. In this study, our objective was to

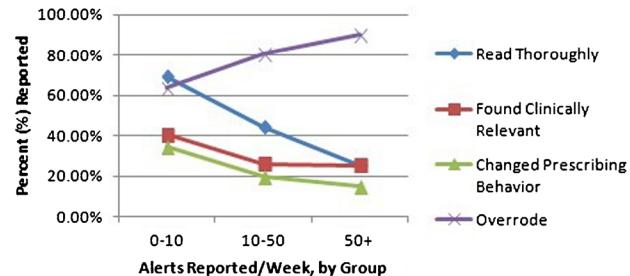

evaluate the relationships between user perceptions of Drug-Drug Interaction (DDI) and Drug-Allergy Interaction (DAI) alert volume, content, and user acceptance.

METHODS: We conducted a survey of user perceptions of DDI and DAI alerts using a validated survey tool, developed by Zheng, et al. The purpose of this survey was to understand the relationship between the acceptance of alerts to users' perceptions of the number and content of these alerts. To increase the generalizability of our evaluation we included a multi-national sample of EMRs, with users of both home-grown and commercially available products, surveying physicians at seven healthcare institutions in two countries. The EMRs evaluated were two commercially available products and four home-grown products. A total of 1,423 internal medicine physicians were invited to participate in the study. The survey questions evaluated providers' perceptions regarding the volume of alerts they received. Specifically, providers were asked to quantify the DDI/DAI alerts they receive in an average week, read thoroughly, found clinically relevant, changed their prescribing behavior, and overrode. We performed descriptive statistics on the survey responses to establish correlations between perception of alert frequency, alert relevancy, and alert override. We ran the means in three groups based on the number of alerts reported per week; 1–10 alerts per week (group 1), 11–50 (group 2), and greater than 50 (group 3).

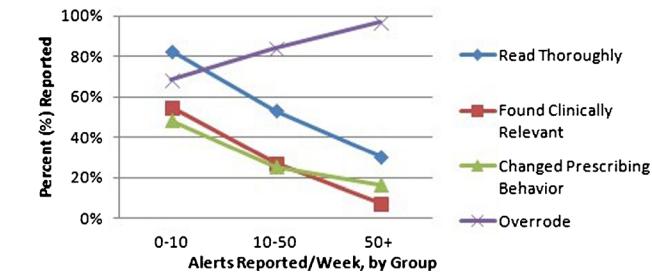

RESULTS: Of the 1,423 physicians invited to participate, 342 consented to participate for an overall response rate of 24 %. For both DAI and DDI alerts across all three groups, we found that as the number of perceived alerts increases, the percentage of providers who report reading, finding these alerts relevant, or changing prescribing behaviors based on the information provided decreases while the number of alerts overridden increases (Table 1, 2). Overall, participants estimated receiving a greater number of DDI (22.9) than DAI (13.8) alerts per week, but were more likely to override DAI than DDI alerts, with reported override rates of 83.22 % and 78.5 %, respectively.

CONCLUSIONS: This is the first study to establish an empirical correlation between the perceptions of physicians on alerts to alert acceptance. Physicians who perceive receiving a high number of alerts are less likely to read them, find them clinically relevant, allow them to affect their prescribing behavior, and more likely to override them. Future research should focus on how providers' perceptions of alert volume can be improved. Decreasing the volume of interruptive alerts may foster a more positive attitude of physicians towards CDS alerting in EMRs.

a Provider Perceptions of Drug-Drug Interaction Alerts

b Provider Perceptions of Drug-Allergy Interaction Alerts

AN INTERNET-BASED STUDY CHARACTERIZING THE ASSOCIATION BETWEEN PAIN SEVERITY AND THE BURDEN OF FIBROMYALGIA IN THE US Elizabeth T. Masters²; Caroline Schaefer¹; Rachael Mann³; Joseph C. Cappelleri⁴; Shoshana Daniel¹; Edgar Adams¹; Gergana Zlateva²; Heather McElroy⁶; Arthi Chandran²; Annlouise Assaf⁴; Michael McNett⁷; Philip Mease^{8,9}; Stuart Silverman¹⁰; Roland Staud¹¹. ¹Covance Market Access Services Inc, Gaithersburg, MD; ²Pfizer Inc, New York, NY; ³Covance Market Access Services Inc, San Diego, CA; ⁴Pfizer Inc, Groton, CT; ⁵Covance Market Access Services Inc, Conshohocken, PA; ⁶Covance Market Access Services Pty Ltd, Sydney, NSW, Australia; ⁷Aurora Pain Program, Milwaukee, WI; ⁸Swedish Medical Center, Seattle, WA; ⁹University of Washington, Seattle, WA; ¹⁰Cedars-Sinai Medical Center, Beverly Hills, CA; ¹¹University of Florida, Gainesville, FL. (Tracking ID #1922702)

BACKGROUND: Although patients with fibromyalgia (FM) report a variety of symptoms that impact function and quality of life, chronic widespread pain is the hallmark symptom. Pain management in patients with FM is challenging, and the presence of pain contributes to the overall burden. This study characterizes the burden of FM by pain severity in the US.

METHODS: Subjects ≥18 years old with FM were identified during a study to determine the prevalence and burden of FM and chronic widespread pain in a sample of US adults recruited from a national online panel. Given the gender distribution of FM, females were oversampled (80:20). FM confirmation was made by physician evaluation during a site visit among 350 with and 125 subjects without chronic widespread pain. A total of 171 FM subjects subsequently completed an online questionnaire to assess clinical characteristics, patient-reported outcomes (including but not limited to the Revised Fibromyalgia Impact Questionnaire [FIQ-R], Brief Pain Inventory-Short Form [BPI-SF], Medical Outcomes Study Sleep Scale [MOS-SS], and Short Form 12-Item Heath Survey, version 2 [SF-12]), and direct and indirect costs during the past 3 months. Subjects were categorized by pain severity using cutoff scores on the BPI-SF (mild, 0–3; moderate, 4–6; severe, 7–10); statistical significance was evaluated at the 0.05 level across severity levels with ANOVA (continuous variables) and chi-square or Fisher's exact test (categorical variables).

RESULTS: Mild, moderate, and severe pain were reported by 27 (15.8 %), 57 (33.3 %), and 87 (50.9 %) FM subjects, respectively. Across pain severity levels, age, gender, and race were similar. However, the percentage of subjects employed for pay was lower with increasing pain severity: 70.4 %, 45.6 %, and 23.0 % for mild, moderate, and severe, respectively ($P<0.0001$). Among those reporting at least one comorbid condition, greater pain severity was associated with a higher mean ± standard deviation (SD) number of comorbid conditions, from 3.0 ± 2.0 (mild) to 4.5 ± 3.1 (moderate) and 5.8 ± 2.9 (severe) ($P<0.0001$). The FIQ-R and its subscales (Function, Overall Impact, and Symptom Intensity) showed progressive worsening with increasing pain severity (all $P<0.0001$). The MOS-SS Overall Sleep Problems Index score indicated poorer sleep with increasing pain ($P<0.0001$). Pain severity was significantly associated with poorer health status, as indicated on the SF-12 domains (all $P<0.05$) as well as the Physical Component Summary ($P<0.0001$). Higher total costs during the past 3 months were associated with increasing pain ($P=0.0053$), with the highest costs among those with severe pain (mean ± SD: \$9,553 ± 9,601 relative to moderate (\$6,701 ± 6,477) and mild (\$4,143 ± 4,657). Across all severity levels, indirect costs were the primary driver of total costs, and increased as pain increased ($P=0.0063$).

CONCLUSIONS: Severe pain was common in a broadly representative sample of FM patients, underscoring the challenges of pain management. Pain severity was significantly associated with sleep, function, and health status, indicating that the burden of FM was greater among subjects with more severe pain. The economic burden of FM was higher with greater pain severity; the highest costs were observed among subjects with severe pain. These findings highlight the importance of comprehensive treatment and the need for effective pain management strategies, especially among those experiencing greater pain levels.

AN OBJECTIVE STRUCTURED TEACHING EXAM DEMONSTRATES THAT CLINICAL FACULTY PERFORM BETTER AT FEEDBACK GIVING WHEN INSTRUCTED TO FOCUS ON FEEDBACK SKILLS Sheira Schlair¹; Sharon Parish¹; Mooseong Heo²; Felise Milan¹. ¹Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1937665)

BACKGROUND: The Objective Structured Teaching Exam (OSTE) is an emerging faculty development and teaching assessment tool. Often the only data available to assess clinical teaching quality are learner evaluations, which are subject to bias. The objectives of this evaluation were to assess faculty's areas of effectiveness and those needing improvement on simulated clinical teaching encounters.

METHODS: 18 faculty participants (FP), six expert observers (EO) and 10 standardized students (SS) participated in a three-station OSTE at AECOM's Clinical Skills Center. Cases and checklists were developed by a team of experts and further modified with input from SSs and EO after a 3-hour training session. FPs participated in three stations: (1) Attending rounds involving a medical error with a team of an intern, resident and sub-intern ("attending rounds"); (2) Bedside teaching of a focused cardiac exam in a patient with chronic atrial fibrillation ("bedside teaching"); and (3) Learner feedback to a medical student with professionalism issues in his clinical work ("feedback"). FPs were assessed by EO who completed station-specific checklists consisting of core teaching skills, case specific skills, and two global items (communication and teaching skills) using a behaviorally-anchored 5-point scale (1 = poor to 5 = excellent). Inter-station comparisons were performed using a mixed effects linear regression model followed by a Bonferroni correction, and paired t-tests were used to assess the impact of specific teaching domains on overall station performance.

RESULTS: EO assessment of FP performance showed that core teaching skills were significantly different across stations: (1) FPs' instructional skill scores were higher in the bedside teaching and attending rounds stations as compared to the feedback station (4.11, 3.83, 2.85, $p=0.0340$); (2) FPs' feedback scores were higher in the feedback station (4.00 vs. 2.97 for attending rounds, 3.81 for bedside teaching; $p=0.0358$) and the highest rated teaching skills in the entire OSTE; (3) Case specific skills were significantly worse in the feedback as compared with attending rounds and bedside teaching stations (3.12, 4.03 and 4.33, respectively; $p=0.0014$). FPs' feedback skills had a negative impact on bedside teaching and attending rounds' overall station performance, while it had a significantly positive impact on the feedback station performance.

CONCLUSIONS: Faculty case specific skill performance was stronger in the attending rounds and bedside teaching cases as compared to the professionalism station. However, feedback skills were superior and most highly rated in the feedback station in which feedback was the specific teaching task being evaluated. These findings raise the question of whether feedback can be effectively delivered while concentrating on a clinical task. One possible explanation for is that when clinical teachers have multiple tasks to juggle, feedback may not be given priority and perhaps may be performed less skillfully. Implications are that feedback to learners may need to be explicitly separated from other tasks in the daily clinical workflow. In addition, these findings might suggest the need for systematic faculty development in feedback-giving in complex clinical environments.

AN OCCULT FINDING IN HEPARIN DRIP ORDER SET Daniel A. Kim²; Ileana L. Ponor^{1,2}; Rajanigandhi Hanumanthu³; Scott Wright². ¹Johns Hopkins University School of Medicine, Baltimore, MD; ²Johns Hopkins University School of Medicine, Baltimore, MD; ³Johns Hopkins Bayview Medical Center, Baltimore, MD. (Tracking ID #1939349)

BACKGROUND: Order sets in electronic medical records (EMR) have been shown to reduce variation in clinical practice, to increase quality of care, and to reduce costs. However, it is important to continually evaluate the benefit and appropriateness of existing order sets. Some order sets may not be evidence-based, and all need to be periodically reviewed and updated. There have been efforts to reduce, or even eliminate, fecal occult blood test (FOBT) in hospitalized patients. Friedman's 2010 study asserts that there is no place for FOBT in an acute hospital setting as the test leads to inappropriate clinical decisions with considerable costs. One example of using FOBT in an ill-chosen and ill-timed manner, is the inclusion of FOBT in the heparin drip order set, which occurs at our hospital and others. Our study was conducted to assess the frequency of FOBT ordered and sent, as well as the results, documentation, and change in management among hospitalized patients who are on heparin drip therapy.

METHODS: A retrospective study of 898 adult hospitalized patients, who had heparin drip ordered at a single academic medical center during a 6 month period (from November 2012 to May 2013) was conducted. Demographics, hospital admission information, diagnosis, discharge disposition, laboratory data, and indication for heparin drip were collected. For patients with FOBT sent, further data was gathered and analyzed for FOBT results, documentation, and influence over clinical decision making and management.

RESULTS: During the 6 month period studied, 898 patients had heparin drip ordered through the available order set, which includes a nurse collect lab order for FOBT. A total of 128 (14.3 %) patients had FOBT sent, of which 33 (25 %) came back positive. About half (51.5 %) of these results were documented by a provider either in a progress note (36 %) or discharge summary (36 %). An occult blood test was sent despite the fact that seven patients (21 %) had obvious signs of bleeding. In only one instance, was the heparin drips were stopped as a direct result of the positive test. From all positive tests, 7 (21 %) resulted in a gastroenterology consult, with four of these patients (57.1 %) getting an

inpatient endoscopy. These did not change anticoagulation management in a single patient. The endoscopies were unremarkable in three patients (no cause of bleed found) and in one patient adenocarcinoma was diagnosed via a polyp biopsy. Among the 14 patients that were discharged home ($n=14$), approximately 43 % were readmitted within 90 days with a diagnosis of GI bleed.

CONCLUSIONS: Regular review of order sets in our EMRs, with careful consideration of the consequences, is essential. While the automatic FOBT order in the heparin drip order set at our hospital seems ineffective, we were surprised to learn that the order is ignored by our nurses recurrently. Because the FOBT results changed management very infrequently, it is probably not indicated to be included in the heparin order set. That said, any positive FOBT that is noted in the hospital should be passed on to the patient and the primary care physician, particularly given the very high 90 day readmission rate for a GI bleed.

ANALYSIS OF 256 CASES OF CLASSIC FEVER OF UNKNOWN ORIGIN

Masashi Yamanouchi; Toshio Naito; Yuki Uehara; Hirohide Yokokawa; Tomohiro Hosoda; Yukiko Watanabe; Takayasu Shiga; Akihiro Inui; Yukiko Otsuki; Kazutoshi Fujibayashi; Hiroshi Isomura; Teruhiko Hisaoka. Juntendo University School of Medicine, Tokyo, Japan. (Tracking ID #1937281)

BACKGROUND: Fever of unknown origin (FUO) can be caused by many diseases that vary depending on region and time period. Studies on the causes of FUO in Japan has been small number of cases, often representing regional studies limited to a single hospital. The aim of the present study were <1> Age group, sex, and causes of FUO (%) in all patients. <2> Differences in causes of FUO (%) between patients 65 years old and older, and <65 years old. <3> Differences in causes of FUO (%) between the periods 1994–2003 and 2004–2012. <4> Number of cases requiring 150 days and longer from the time of fever onset for diagnosis.

METHODS: For the present single-institution retrospective observational study, data were extracted from the medical records of patients ≥ 18 years old who met the criteria for classic FUO and were hospitalized between August 1, 1994, when our department was established, and December 31, 2012. Durack and Street's criteria for classic FUO were used in this study: fever $\geq 38^{\circ}\text{C}$ at least twice over a ≥ 3 -week period, without a diagnosis after three outpatient visits or 3 days of hospitalization, and no diagnosis of HIV or immunodeficiency prior to the fever.

RESULTS: A total of 256 patients were enrolled in this study, including 131 men and 125 women, with a median age of 55 years (range, 18–94 years). The most frequent age group comprised patients in their 60s. Patients 65 years old and older accounted for 33.2 % (85/256) of all patients. The cause of FUO was infection in 27.7 % of patients ($n=71$), Non infectious inflammatory disease (NIID) in 18.4 % ($n=47$), malignancy in 10.2 % ($n=26$), other in 14.8 % ($n=38$), and unknown in 28.9 % ($n=74$). The most common single cause was HIV/acquired immunodeficiency syndrome (AIDS) in 17 patients, accounting for 25 % of all infections. Among these, 16 patients were <65 years old. The next leading causes were malignant lymphoma and infective endocarditis in 12 patients each; with these causes, four patients and 10 patients, respectively, were <65 years old. The fourth leading cause was polymyalgia rheumatica in 10 patients; seven were 65 years old and older. In patients 65 years old and older, compared to those <65 years old, percentages of infections (21.7 % vs. 30.6 %) and other causes (7.2 % vs. 18.5 %) were lower, whereas percentages of NIID (27.7 % vs. 13.9 %) and malignancy (14.5 % vs. 8.1 %) were higher. The percentage of unknown causes was the same (28.9 %) in both patients <65 years old and 65 years old and older. The trend in 2004–2012, compared to 1994–2003, was similar to that in the 1990s in an overseas report. In eight of the 256 patients, 150 days and longer were required from the time of fever onset for diagnosis. The longest time was 300 days in a case of adult Still's disease.

CONCLUSIONS: This study reviewed patients with classic FUO evaluated at our hospital department since it was established. Our study found that together with the increase in HIV patients in Japan, HIV/AIDS is now the most common cause of FUO. In addition, the percentage of unknown causes of FUO has increased, now exceeding 20 % of cases. As the present study collated data from a long period and reviewed the largest number of FUO cases in Japan to date, these findings will serve as a useful reference for the future care of FUO patients.

ANALYSIS OF PREDICTIVE FACTORS OF BACTEREMIA AMONG INPATIENTS OF GENERAL MEDICINE Sayato Fukui¹; Yuki Uehara¹; Toshio Naito¹; Teruhiko Hisaoka¹; Osamu Takahashi². ¹Juntendo University School of Medicine, Tokyo, Japan; ²St. Luke's Life Science Institute, Tokyo, Japan. (Tracking ID #1937325)

BACKGROUND: Criteria to take blood culture from patients with suspicion of severe infection has not been established, and decision depends on each physician's opinion. Several report investigated predictive factors for positive blood culture results among ICU patients or aged patients, but analysis of predictive factors among patients hospitalized in department of general internal medicine has not been reported yet. This study was performed in inpatient wards of general medicine of Japanese university hospital to clarify the predictive factors of bacteremia and to identify patients from that blood cultures should be taken.

METHODS: This cross-sectional study was performed at the department of general medicine in Juntendo University Hospital, Tokyo, Japan, from January 2011 to December 2012. All inpatients from that blood cultures were taken were included in this study. The results of blood cultures of the patients were collected from the database of the clinical laboratory, and only the first culture results were used for analysis in each patient if blood cultures were taken repeatedly to check the treatment effects or to deny bloodstream infection. Other clinical information was also extracted by chart review; age, sex, height, weight, admission except from their own houses, type of devices used when blood cultures were taken, antimicrobial use within 2 weeks, surgery within a month, hemodialysis, use of immunosuppressive agents, active malignant diseases and HIV infection. Body temperature, systolic and diastolic blood pressure, pulse rate, white blood cell count with percentages of neutrophils and lymphocytes, blood urea nitrogen, creatinine, glucose and CRP levels just at or before blood culture sampling were extracted from medical charts, as well. Predictive factors of bacteremia were analyzed using *t*-test or Chi-square test, followed by multivariate logistic regression model.

RESULTS: A total of 223 patients (M:F = 130:93, 64±19 years old) were included in this study and 60 patients (26.8 %) had positive blood culture results. Multivariate logistic regression model showed that older age (OR=1.5, 95%CI=1.1–2.0, $p=0.017$), higher temperature (OR=2.7, 95%CI=1.8–4.1, $p<0.01$) and higher neutrophil percentage (OR=1.1, 95%CI=1.0–1.1, $p<0.01$) were the independent predictors of bacteremia. In contrast, other factors were not predictors of bacteremia; for example, CRP was not associated with bacteremia ($p=0.56$). Area under the ROC curve of this model was 0.84 (95%CI=0.79–0.90).

CONCLUSIONS: Existence of bacteremia can be highly predicted by fundamental clinical information such as age, body temperature and neutrophil percentage. Our results emphasize the importance of taking blood culture from elderly even though they are not febrile, and the importance of ordering differential count of white blood cell in addition to total cell count. To confirm the patient characteristics that have diagnostic and therapeutic benefits from blood culture, further prospective study should be performed with standard criteria and methods for taking blood culture.

ANNUAL SALARY OR HOURLY WAGE? HOW 4TH YEAR MEDICAL STUDENTS CONSIDER FINANCIAL COMPENSATION WHEN SELECTING A SPECIALTY

Kent DeZee^{1,2}; Elexis McBee^{2,1}; Nathalie Paolino^{2,1}. ¹Uniformed Services University, Bethesda, MD; ²Walter Reed National Military Medical Center, Bethesda, MD. (Tracking ID #1939766)

BACKGROUND: Financial compensation is a well known consideration in medical student selection of their medical discipline, particularly as it relates to primary care specialties. However, the manner in which students define financial compensation is unclear. The purpose of this study is to determine whether or not 4th year medical students view annual salary and hourly wage as equally important when selecting their specialty in order to help guide future research.

METHODS: The authors conducted a cross sectional survey of 4th year medical students from the University of Chicago, the University of Pennsylvania and all 4th year medical students with a military service obligation in the U.S. during the 2011–2012 academic year. Following the residency match, participants were invited to participate in the study via e-mail. The student's self-reported specialty choice in the residency match was classified into one of four categories: 1) primary care (PC: internal medicine, family medicine, pediatrics, and internal medicine-pediatrics), 2) non-controllable lifestyle specialties (Non-CL: general surgery, neurosurgery, obstetrics and gynecology, orthopedics, and urology), 3) controllable lifestyle, considered PC (CL-considered PC: all other specialties in which the student listed PC as a secondary choice), and 4) controllable lifestyle, did not consider PC (all other specialties in which the student did not list PC as a secondary choice). Using a five-point Likert-type scale (1 = not important at all; 5 = extremely important), respondents rated the

importance of two items related to attending salary when choosing their specialty: 1) annual salary earned by civilian (not military) physicians in their chosen specialty and 2) hourly wage of civilian (not military) physicians in their chosen specialty. In addition, the amount of self-reported educational debt and length of military service obligation were collected. One-way ANOVA was used to compare the mean of the importance of annual salary and hourly wage to the four categories of specialty choice, with a Bonferroni multiple comparison test. Effect sizes were calculated to measure the strength of statistically significant associations. T-tests and stratified analyses were conducted to test for confounding by military service and level of debt.

RESULTS: The response rate for the questionnaire was 46 % (540/1184). Attending physician annual salary was slightly more important than hourly wage when selecting a specialty (mean annual salary 2.6, mean hourly wage 2.4, $p < 0.0001$, paired T -test). Students selecting PC rated annual salary as less important than all other students (PC mean 2.3, all other students 2.8, $p < 0.0001$, small effect size of 0.42). When rating attending hourly wage, the importance was different between all four specialty groups (PC mean: 2.2, Non-CL mean: 2.4, CL-considered PC mean: 2.6, CL-did not consider PC mean: 2.8), with a moderate effect size (0.57) between PC and CL-did not consider PC, and a small effect size (0.40) between both PC and CL-considered PC as well as Non-CL and CL-did not consider PC. The results were not affected by educational debt or military service obligation.

CONCLUSIONS: Fourth year medical students placed slightly more importance on annual salary versus hourly wage when selecting their specialty. However, these factors were equally important for students who chose a controllable lifestyle specialty and did not consider primary care. Future studies of specialty choice should select the type of financial compensation question or intervention (annual salary or hourly wage) based on the research goal and the intended specialty type of the student to be studied.

ANTIBIOTIC SUSCEPTIBILITIES OF URINARY ISOLATES IN OLDER ADULTS

Theresa A. Rowe; Lee Lindquist; Abel Kho. Northwestern University Feinberg School of Medicine, Chicago, IL. (Tracking ID #1927517)

BACKGROUND: Background: Older adults are at an increased risk for development of multi-drug resistant organisms because of compounded exposure to antibiotics. Clinicians empirically treat suspected urinary tract infections (UTI) in older adults, selecting antibiotics based on guidelines intended for younger patients. No prior studies have examined whether there are age-related differences in UTI antibiotic susceptibility. We sought to identify antibiotic susceptibility patterns of urinary isolates in outpatient older adults and compare them to younger patients over a 3-year period.

METHODS: Retrospective analysis of all adult outpatients with a positive urine culture who received antibiotic treatment for UTI within 3 days. The most common organisms Escherichia Coli (E. Coli) and Klebsiella spp. were tested for resistance to commonly prescribed antibiotics. We compared resistance patterns of adults over the age of 65 to younger adults under the age of 65 using descriptive statistics and chi square analysis.

RESULTS: Urine cultures from 8,659 patients were reviewed. For E. Coli the percentage of resistance for adults ≥ 65 , compared to adults < 65 were: Ciprofloxacin (31.97 % in 65 years and older patients vs. 16.85 % in under 65 year old patients; $p < 0.01$), Trimethoprim/Sulfamethoxazole (30.12 % vs 25.19 %; $p < 0.01$), Ampicillin/Sulbactam (19.47 % vs 19.36 %), Cefuroxime (5.27 % vs 4.23 %; $p < 0.05$), Nitrofurantoin (1.80 % vs 1.47 %). For the second most common organism, Klebsiella species: Ciprofloxacin (5.28 % vs 4.99 %), Trimethoprim/Sulfamethoxazole (12.61 % vs 13.59 %), Ampicillin/Sulbactam (6.88 % vs 12.85 %; $p < 0.01$), Cefuroxime (6.39 % vs 7.91 %), Nitrofurantoin (26.28 % vs 24.36 %).

CONCLUSIONS: Older adults with UTIs have different resistance patterns to microorganisms when compared to younger patients. Current clinical guidelines for treatment may not reflect these differences. Clinicians need to be aware of the resistance patterns unique to older adults so that they can be appropriately treated

ANTICOAGULATION-RELATED PROCESSES OF CARE AND SHORT-TERM OUTCOMES IN ELDERLY PATIENTS WITH ACUTE VENOUS THROMBOEMBOLISM

Charlene Insam¹; Marie Méan¹; Andreas Limacher²; Nicolas Rodondi¹; Drahomir Aujesky¹. ¹Bern University Hospital, Bern, Switzerland; ²University of Bern, Bern, Switzerland. (Tracking ID #1937453)

BACKGROUND: Whether recommended anticoagulation-related processes of care are associated with improved clinical outcomes in elderly patients with acute venous thromboembolism (VTE) remains uncertain.

METHODS: We studied 991 in- and outpatients aged ≥ 65 years with acute VTE in a prospective multicenter Swiss cohort study (09/2009–03/2012). We assessed the performance of the following processes of care recommended by the American College of Chest Physicians: use of low-molecular-weight heparin or fondaparinux rather than unfractionated heparin in patients with deep vein thrombosis or non-massive pulmonary embolism, parenteral anticoagulation (PAC) ≥ 5 days, start of oral anticoagulation (OAC) within 24 h of VTE diagnosis, and achievement of an international normalized ratio (INR) ≥ 2.0 for ≥ 24 h before stopping PAC. Outcomes were overall mortality, VTE-recurrence, and major bleeding at 6 months and the length of hospital stay. We assessed the association between processes of care and clinical outcomes using Cox regression models, and the association between processes of care and length of hospital stay using the lognormal survival model, adjusting for multiple patient baseline characteristics.

RESULTS: Overall, 9 % of patients died, 2 % had VTE- recurrence, and 7 % had major bleeding at 6 months after the index VTE. The median length of hospital stay was 8.0 days (interquartile range 5.0; 11.0). Starting OAC within 24 h of VTE diagnosis was associated with a lower risk of overall mortality (adjusted hazard ratio [HR] 0.44, 95 % confidence interval [CI] 0.21–0.92) and major bleeding (adjusted HR 0.35, 95 % CI 0.18–0.66) and a decreased length of stay (adjusted time ratio [TR] 0.77, 95 % CI 0.69–0.85). While the use of low-molecular-weight heparin or fondaparinux significantly decreased the length of stay (adjusted TR 0.87, 95 % CI 0.77–0.97), the achievement of an INR ≥ 2.0 for ≥ 24 h before stopping PAC increased the length of stay (adjusted TR 1.20, 95 % CI 1.08–1.34). None of the processes of care were associated with VTE recurrence. We found no association between PAC for ≥ 5 days and outcomes.

CONCLUSIONS: In elderly patients with acute VTE, two out of four recommended processes of care were associated with improved clinical outcomes and/or a decrease in length of hospital stay. These processes should be implemented when treating elderly patients with acute VTE.

ANTIPSYCHOTIC MEDICATION USE AND THE RISK FOR HOSPITAL-ACQUIRED PNEUMONIA

Shoshana J. Herzig¹; Michael B. Rothberg³; Jamey R. Guess¹; Long H. Ngo¹; Jerry H. Gurwitz⁴; Edward R. Marcantonio^{1,2}. ¹Beth Israel Deaconess Medical Center, Boston, MA; ²Beth Israel Deaconess Medical Center, Boston, MA; ³Cleveland Clinic, Cleveland, OH; ⁴UMass Memorial Medical Center, Worcester, MA. (Tracking ID #1933568)

BACKGROUND: With the advent of atypical antipsychotic medications, use of antipsychotics has markedly increased in long-term care facilities, often in patients without a psychiatric diagnosis. Both typical and atypical antipsychotics have been associated with pneumonia in community and nursing home settings. However, rates of antipsychotic use in the acute hospital setting and the association between this use and hospital-acquired pneumonia (HAP) are unexplored.

METHODS: We studied an observational cohort of all patients admitted to a large academic medical center in Boston, Massachusetts from 1/2007 to 7/2013, at least 18 years of age, and hospitalized for at least 2 days. We excluded transfers from outside hospitals, patients admitted to the psychiatry service, and patients with a diagnosis of a psychotic disorder. Data were collected from electronic medical information databases at the medical center. We defined antipsychotic use as any pharmacy charge for an antipsychotic medication, subclassified as typical and atypical. The primary outcome was HAP, defined as any ICD-9 for bacterial pneumonia coded as not present on admission. We used a generalized estimating equation logistic regression model to control for repeated admissions and confounders. Our model included 40 variables, chosen based on hypothesized associations with antipsychotic use and/or HAP, including demographics, comorbidities as defined by Elixhauser et al., and concurrent medication use (sedatives, opioids, immunosuppressive agents, acid-suppressive medications). We assessed for effect modification by age using a dichotomous variable where we varied the cutpoint ($<$ versus $\geq 60, 65, 70, 75$ years).

RESULTS: Our cohort included 146,680 admissions (median age = 56 years; 39 % male). Antipsychotics were used in 18,047 (12.3 %) admissions (8.0 % typical and 5.8 % atypical, with 1.5 % exposed to both), and HAP occurred in 2,992 admissions (2.0 %). See table for rates of HAP and adjusted odds of HAP by exposure category. Use of each subclass of antipsychotic medication was associated with increased odds of hospital-acquired pneumonia, with highest risk seen in those admissions with exposure to both classes. There was no effect modification by age at any of the chosen cutpoints.

CONCLUSIONS: Antipsychotic use was common during hospitalization, occurring in 12 % of non-psychiatric admissions. Both typical and atypical antipsychotics were associated with increased odds of hospital-acquired pneumonia after extensive adjustment for patient characteristics and concurrent medication exposures. Given their associated risks, further scrutiny is warranted regarding prescribing practices of antipsychotic medications in the acute hospital setting.

Rates of HAP and adjusted odds of HAP by exposure category

Exposure Status*	n (% of cohort)	HAP n (% of exposure category)	Adjusted OR for HAP [95 % CI]
Neither	128,633 (87.7)	1,970 (1.5)	Reference
Typical antipsychotic	9,512 (6.5)	392 (4.1)	1.6 [1.4–1.8]
Atypical antipsychotic	6,276 (4.3)	339 (5.4)	1.7 [1.5–1.9]
Both	2,259 (1.5)	291 (12.9)	2.5 [2.1–2.9]

ANTIRETROVIRAL DRUG EXPENDITURE, PRICING AND JUDICIAL DEMAND: AN ANALYSIS OF FEDERAL PROCUREMENT DATA IN BRAZIL FROM 2004–2011 Jing Luo¹; Claudia Osorio-de-Castro²; Maria Olivera²; Mariana Ramos³; Aurelio Maia³. ¹Yale University School of Medicine, New Haven, CT; ²Sergio Arouca National School of Public Health, Rio de Janeiro, Brazil; ³Ministry of Health, Brasilia, Brazil. (Tracking ID #1942220)

BACKGROUND: Previous studies have described expenditures for antiretroviral (ARV) medicines in Brazil through 2005. While prior studies examined overall expenditures, they have not analyzed drug procurement data in order to describe the role of court litigation on access and pricing.

METHODS: ARV drug procurement from the years 2004–2011 was obtained through the general procurement database of the Brazilian Federal Government (SIASG). Procurement was measured in Defined Daily Doses per 1000 persons-under-treatment. Expenditures and costs were calculated and expressed in US Dollars. Justifications for ARV purchases were examined in order to determine the relationship between health litigation and incorporation into Brazil's national treatment guidelines.

RESULTS: Drug procurement of ARVs from purchased sources underwent marked expansion in 2005, peaked in 2009, and stabilized to 2008 levels by 2011. Expenditures followed procurement curves. Newer medications were on average four times more expensive than older medications. Judicial actions initially resulted in purchases of newer medications for a select number of patients in Brazil but ultimately expanded availability to a larger population through incorporation into the national treatment guidelines. ARVs were purchased at the lowest prices through auction, intermediate prices through single suppliers, and highest prices through emergency procurement resulting from judicial action.

CONCLUSIONS: Drug procurement and expenditures for ARVs in Brazil varied between 2004 and 2011. Medications which once represented a large proportion of federal drug expenditures have been largely eliminated due to domestic production. Judicial demand has resulted in the procurement of large quantities of newer, more expensive medications. In order for the AIDS treatment program to remain sustainable, efforts should be pursued to reduce prices through price negotiation and other public health flexibilities.

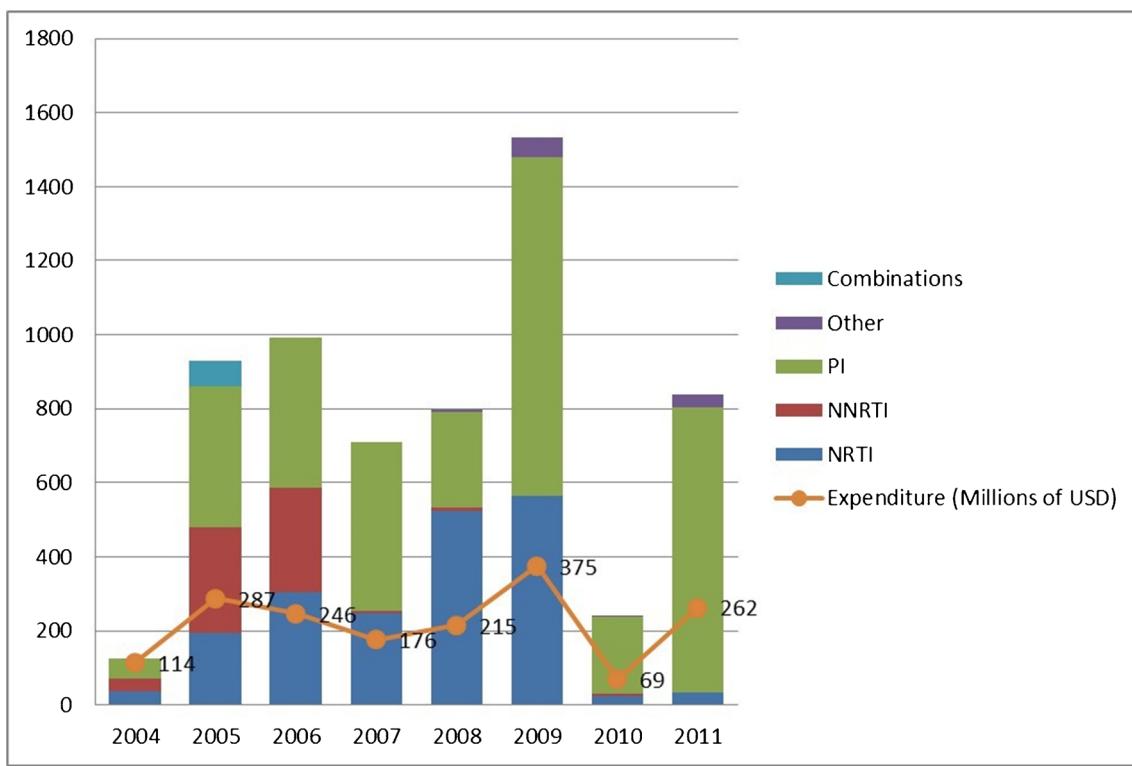

Figure 1. Drug Procurement and total expenditures for antiretroviral medicines in Brazil from 2004 and 2011.

APPROPRIATENESS OF PREVENTIVE CARE FOR ANGIOPATHIC COMPLICATIONS IN OUTPATIENTS WITH DIABETES Idris Guessous^{1,5}; Sophie Excoffier Bottaro¹; Manuel R. Blum²; Nicolas Rodondi²; Jacques Cornuz³; Lukas Zimmerli⁴; Jean-Michel T. Gaspoz¹. ¹Geneva University Hospitals, Geneva 14, Switzerland; ²Inselspital, University of Bern, Bern, Switzerland; ³University of Lausanne, Lausanne, Switzerland; ⁴University Hospital of Zurich, Zurich, Switzerland; ⁵Institute of Social and Preventive Medicine, Centre Hospitalier Universitaire Vaudois, University of Lausanne, Lausanne, Switzerland. (Tracking ID #1937359)

BACKGROUND: Preventive care of major diabetic angiopathic complications (foot ulcers and retinopathy) is essential. However, data on the prevalence of and factors associated with preventive care of angiopathic complications in outpatients with diabetes are very limited and non-existent within the Swiss context of universal health care coverage. We aimed to determine the prevalence of appropriate preventive care of angiopathic complications in outpatients with diabetes, and to identify factors associated with appropriate preventive care of angiopathic complications.

METHODS: We used data from a retrospective cohort study (the Corif study) that examined recommended preventive care in a random sample of patients aged 50–80 years followed over 2 years (2005–2006) in four Swiss university primary care settings using RAND's Quality Assessment Tools indicators. We defined appropriateness of preventive care of angiopathic complications using the American Diabetes Association recommendations: annual foot (pallesthesia and visual exam) and ophthalmologic exam. Age-, sex-, center-adjusted regression models were conducted.

RESULTS: Among the 292 outpatients with diabetes included, 59.2 % had appropriate preventive foot care and 55.8 % had appropriate preventive eye care. Only 34.6 % had appropriate preventive care of both foot and eye. Number of GP visits (Odds Ratio=1.07, 95%CI 1.02–1.11) and Hb1Ac measured at least 2×/year (OR=2.56, 1.34–4.90) were associated with appropriate foot preventive care. Obesity (OR=0.37, 0.21–0.65) and hyperlipidemia (OR=2.47, 1.38–4.43) were associated with appropriate eye preventive care. Hb1Ac measured at least 2×/year (OR=2.56, 1.34–4.90), obesity (OR=0.53, 0.29–0.95), and hyperlipidemia (OR=2.36, 1.23–4.51) were associated with appropriate preventive care of both foot and eye.

CONCLUSIONS: Preventive care of diabetic angiopathic complications is frequently inappropriate among outpatients. Particular attention should be paid to obese patients with diabetes.

ARE PATIENT-CENTERED MEDICAL HOME PRACTICES ASSOCIATED WITH BETTER ACCESS TO PRIMARY CARE SERVICES? Jaya Aysola¹; Karin V. Rhodes²; Daniel Polksky¹. ¹University of Pennsylvania, Philadelphia, PA; ²University of Pennsylvania, Philadelphia, PA. (Tracking ID #1940136)

BACKGROUND: Patient-centered medical homes (PCMH) have gained prominence as models designed to promote high quality cost effective primary care. An integral component of the PCMH model is providing enhanced access to primary care. However, the potential effect of PCMHs on access to primary care services has not been examined. Our study evaluated whether PCMH practices in ten US states were associated with better access to care, measured using simulated patient (audit) methodology.

METHODS: We conducted a cross-sectional analysis of publicly available data on practices recognized as National Committee Quality Assurance (NCQA) patient-centered medical homes (PCMH) before June 2013 and data collected through a simulated patient (audit) study. Our primary predictor was whether or not a practice was a NCQA recognized PCMH. Our primary outcome measure was the ability of the caller (simulated patient) to schedule a new appointment. Trained field staff contacted primary care offices in 10 US states between November 2012 and March 2013 posing as individuals seeking a new patient appointment with varying insurance status (private, Medicaid, or uninsured). All eligible primary care offices were identified using a proprietary database of existing physician clinics (SK&A physician file). Callers contacted a stratified random sample of primary care practices treating non-elderly adults in each state, for a total of 10572 requests for appointments at 7266 practices. We merged detailed practice characteristics (number of sites, number of providers, average patient volume, number of exam rooms) from SK&A physician file, and geographic socioeconomic and health care resource information (county-level percent persons below poverty level, percent minority, percent non-elderly uninsured, number of office based primary care providers, and Health Professional Shortage Area designation) from the Area Resource File, into our audit data. We performed multivariable logistic regression model, adjusting for the caller's insurance status and race/ethnicity as well as the practice and geographic characteristics listed above, to estimate the association between PCMH status and our outcome variable. We then fitted a multivariable logistic regression model, including interactions of practice PCMH status and caller's insurance status, adjusting for the same covariates above.

RESULTS: Out of 10572 requests to practices for appointments, 646 (6.1 %) were to NCQA recognized PCMHs. Significant predictors of scheduling new appointments included the caller's insurance status, number of practice exam rooms, percent minority and percent persons in poverty where the practice was located, and the practice's NCQA PCMH recognition status. There were no significant interactions between practice PCMH status and caller's insurance status. Adjusted analysis revealed that calls placed to PCMH practices were significantly more likely to result in scheduled new appointments than calls placed to non-PCMH practices. (Adjusted OR 1.3; 95 % CI 1.0, 1.5; $p=0.02$).

CONCLUSIONS: Our findings suggest that practices recognized as patient centered medical homes, after robust adjustment for individual caller, practice, and geographic variables, were associated with better access to new primary

care appointments for non-elderly adults, those most likely to gain insurance under the Affordable Care Act.

ARE PATIENTS A RELIABLE SOURCE FOR ADVERSE EVENT REPORTING? SURVEY SAYS... Kristy Deep; Megan Minch. Univ of Kentucky, Lexington, KY. (Tracking ID #1939331)

BACKGROUND: Learning from adverse events is an important way to improve healthcare quality and safety. However, events are underreported by healthcare providers. We sought to determine whether patient comments on the post-discharge Healthcare Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey reliably identify adverse events or errors that occur during the hospital stay.

METHODS: HCAHPS surveys with negative comments returned during a 7 month period were reviewed. Comments that described a specific adverse event or error were then analyzed by two independent raters. The patient's medical record was reviewed to corroborate the event. A coding scheme was developed iteratively from the data to categorize the types of adverse events reported by patients. One patient comment could receive multiple codes. We assigned a four-tier harm score for each adverse event: significant harm and/or need for additional treatment, potential harm but outcome unknown, emotional distress/inconvenience, and no harm.

RESULTS: Ninety comments were reviewed, 20 of which were adjudicated as complaints which did not identify quality issues leaving 70 comments for analysis. Of these, 29 (41 %) were corroborated in the medical record. An additional 35 (50 %) were not corroborated by the medical record but were deemed credible based on the level of detail within the patient's report or when the described event was unlikely to be documented (i.e. delays in care). Communication errors were most common and found in 27 events. These included communication between healthcare providers and patients as well as among providers. Other frequent event types were patient education deficits (13), delays in clinical care (13), and medication errors (8). Patients also identified procedural complications (3) and lapses in infection control (2). Ten events (14.2 %) resulted in significant patient harm and/or required additional treatment. Examples include a failure to recognize an abscess resulting in emergent surgery and a patient developing apnea following administration of a medication. Three of these significant harm events were deemed credible but not documented in the medical record. An additional 10 described situations that were potentially harmful but the impact on the patient was unknown. The remainder of the adverse events or errors resulted in either emotional distress/inconvenience (30) or no harm (20).

CONCLUSIONS: Patient comments on the HCAHPS post-discharge survey are a reliable source for insight into the quality of care patients receive. They may also identify significant issues that are not captured by other safety reporting mechanisms.

ARE THERE RACIAL DISPARITIES IN QUALITY OF TREATMENT FOR LOCALLY ADVANCED PROSTATE CANCER? Rajwanth Veluswamy^{1,3}; Rebeca Franco²; Kezhen Fei²; Nina Bickell^{1,2}. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³Icahn School of Medicine at Mount Sinai, New York, NY. (Tracking ID #1940153)

BACKGROUND: African American men are more likely to develop and die of prostate cancer than white men. Past studies have shown lower rates of invasive treatment among black men. However, these studies included early-stage disease for which treatments may not be beneficial. We undertook this study to assess the quality of prostate cancer treatment among men with locally advanced cancer who could benefit from active therapies.

METHODS: All black and a random sample of white men with Gleason Scores of 7+, diagnosed at an inner-city academic center between 2007 and 2012, were identified from pathology and charts abstracted for clinical, pathologic and treatment data. A Steering Committee of experts in prostate cancer care created quality measures of treatment for locally advanced prostate cancer. Underuse of definitive treatments (radical prostatectomy and radiotherapy) was identified using these quality measures.

RESULTS: Overall, 290 black and 255 white men were identified. The average age of the entire cohort was 59 years old (standard deviation [sd] = 8.6, range: 32 to 86) and there was no statistical age difference between races. Black men had more comorbidities (30 % vs 9 %; $p<0.001$) and higher prostate-specific antigen (PSA) levels prior to biopsy (12.4 vs 6.9; $p=0.0027$), but whites were more likely to present with stage three disease (30 % vs 22 %; $p=0.02$). Using D'Amico risk criteria, 14 % of patients were found to have intermediate risk, while 86 % were high risk. The distribution of D'Amico risk between race was not statistically different. Black men

were less likely than white men to undergo radical prostatectomy (79 % vs 91 %, $p < .0001$), but more likely to get external beam radiation therapy (EBRT, 13 % vs 5 %; $p=0.0009$) or brachytherapy (11 % vs 4 %; $p=0.0037$). Of note, 85 % of black and 100 % of white men received the recommended radiotherapy (RT) dose (74Gy). Only 50 % of men undergoing RT received androgen deprivation therapy (ADT), with no racial difference in ADT use. Overall, 5 % of men with locally advanced prostate cancer did not undergo surgery or RT, with no racial difference in underuse. Multivariable analysis using logistic regression showed that patients with intermediate risk were 20 times more likely to experience underuse of definitive treatment as compared to patients with high risk (95 % CI: 7.2-50.3). Additionally, every year increase of age was associated with a 1.06 times higher risk of underuse of definitive treatment (95 % CI: 1.01-1.12). However, even after accounting for potential confounders, race did not play a role in whether patients received definitive treatment according to quality measures.

CONCLUSIONS: The rate of underuse of definitive treatment in men with locally advanced prostate cancer is low and does not appear to be driven by racial differences. However, underuse is significantly associated with patients of intermediate risk and advancing age. We will further investigate why these patients are not receiving active treatment.

ASKING THE PATIENT ABOUT PATIENT-CENTERED MEDICAL HOMES

Jaya Aysola^{1,2}; Rachel M. Werner¹; Judy A. Shea¹. ¹University of Pennsylvania, Philadelphia, PA; ²Children, Philadelphia, PA. (*Tracking ID #1939454*)

BACKGROUND: To date the patient perspective is not an integral component of any of the existing patient-centered medical home (PCMH) measurement standards, although upcoming guidelines necessitate patient-reported experience and satisfaction data in evaluations of practice and provider performance. Despite this, patient understanding of PCMH and their perspectives on their role in the evaluation of practices implementing this model is not known. Therefore, we sought to characterize patients' understanding of the PCMH model, experiences with PCMH practices after transformation, and perceptions on approaches to incorporate patient feedback.

METHODS: We conducted semi-structured interviews of patients from NCQA (National Committee Quality Assurance) recognized PCMH practices at University of Pennsylvania (UPENN). We first surveyed, scored, and ranked all UPENN affiliated PCMH adult primary care practices with three or more providers ($n=23$) using a previously validated scale that quantifies the overall degree of PCMH practice transformation. We then identified the practices, representing the four highest and lowest PCMH transforming practices. To determine if the degree of PCMH practice transformation was related to patient responses, participants were recruited from a pool of adult patients with hypertension and/or diabetes from these eight selected practices. We conducted semi-structured, one-on-one telephone interviews with patients consisting of both open- and closed-ended questions about their experiences with care, and perceptions and understanding of key PCMH domains. Interviews were recorded, transcribed, and imported into NVivo 10 for coding and analysis, using a modified grounded-theory approach.

RESULTS: Of the 19 interviews completed, 52 % were from high-transforming practices, 48 % from low. Fifty-seven percent of the sample was African American and the mean age was 61. Responses did not appear to vary between patients from high and low PCMH transforming practices. None of the participants were aware that their clinic was a PCMH, regardless of whether they were from a high- or low-PCMH transforming practice and most did not know what a PCMH was. Of the key aspects of the PCMH, most participants identified a team-based approach and strong patient-provider partnership as more important to them than enhanced access to care. The majority could not identify additional personnel involved in assisting their PCP in their care. Respondents had differing perspectives about their own role in decision making, with many relying on their PCP to make their treatment decisions. Emerging themes included the following: 1) Patients were unaware of what a medical home is and if their practice was one, irrespective of the practices' degree of PCMH transformation. 2) The patients' lack of knowledge regarding PCMH concepts did not appear to impact their experiences with care and their uniformly positive relationship with their primary care provider. 3) The PCMH domains patients reported as most important for care delivery in theory did not always relate to their preferences in reality. For example, participants reported team-based care as one aspect of PCMH most important to them, yet when discussing their specific experiences at their practice, the majority could not recall any additional personnel teaming with their provider to participate in their care. The majority of participants also reported a strong patient-provider partnership as the other aspect of primary care delivery most important to them; however, when detailing specific preferences, many were less interested in partnering with their provider to share responsibility in medical treatment decisions.

CONCLUSIONS: Our study aimed to examine patient understanding and perceptions of care within PCMHs and whether their experience varied depending on the degree of PCMH practice transformation. We found that patients uniformly lacked awareness of PCMH concepts and the fact their practice was a PCMH, regardless of the degree of transformation reported by the practice. Moreover, this lack of understanding did not appear to impact their experiences with care or overwhelmingly positive relationships with their providers. As we continue to redesign primary care delivery with an emphasis on patient experience measures as performance metrics, further evaluation is needed to determine what if any aspects of how we structure practices relates to patient experience and satisfaction with care.

ASSESSING CONTENT AND QUALITY OF ADVANCE CARE PLANNING DOCUMENTATION IN AN INTERNAL MEDICINE RESIDENT CLINIC

Katherine A. Wang¹; Jacqueline K. Yuen^{2,3}. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³Icahn School of Medicine at Mount Sinai, New York, NY. (*Tracking ID #1913261*)

BACKGROUND: Despite widespread recognition of the need for advance care planning (ACP), there is a troubling communication gap between patients and physicians. One large multicenter study found that of patients who preferred not to be resuscitated, only 52 % had DNR orders. Primary care physicians, given their longitudinal relationships with patients, are ideally positioned to elicit patients' values and goals. Meaningful documentation of these conversations is essential to ensure appropriate communication with other health care providers and to guide future decision-making. Educational interventions have been shown to improve residents' knowledge, skills, and comfort level with ACP and to increase documentation of advance directives, but little data exists about improving the quality of documentation. A novel month-long curriculum was piloted with PGY-2 Internal Medicine (IM) residents from January-June 2013 to improve resident skills with ambulatory ACP discussions and documentation. The objective of this study was to assess the impact of an educational intervention and electronic medical record (EMR) template on the content and quality of documentation of ACP discussions.

METHODS: The setting was an urban academic ambulatory resident clinic. Participants were 41 PGY-2 IM residents who each identified patients with at least one chronic illness and a high likelihood of hospitalization within a year. Residents held visits to address ACP with these patients during the one-month curriculum and documented conversations. An EMR template including prompts for topics introduced in the curriculum (e.g. health care proxy (HCP), disease trajectory, values) was developed for optional use by residents. Investigators conducted a retrospective chart review of all identified patients and measured the frequency of certain discussion elements such as HCP and prognosis. Fisher's exact test was used to compare the templated and free-text notes. Twenty reviewers from IM and Emergency Medicine will rate the notes for usefulness in clinical decision-making in a hypothetical case scenario using a Likert scale, and a qualitative analysis comparing elements of the most highly-rated notes will be performed.

RESULTS: 41 residents received the ACP curriculum. Twenty-nine residents (71 %) documented a total of 34 ACP discussions (Table). The other 12 residents did not document an ACP discussion because the patient did not show up ($n=2$) or for unknown reasons ($n=10$). Of the 34 patients, the mean age was 71.8 years (SD 13.0), 65 % were female, and the most common conditions were hypertension (91 %), diabetes (62 %), chronic kidney disease (32 %), CHF (24 %), COPD (18 %), CAD (18 %), and cirrhosis (12 %). Seventy-one percent had readmit risk score of high or very high (based on number of hospitalizations in last 6 months and certain high risk diagnoses). Of the 34 ACP notes, 6 (18 %) used the template and 28 (82 %) did not. HCP was nearly always addressed (97 % of all conversations), and a signed HCP form was scanned into the chart frequently (56 % of all conversations). Twenty-four percent of notes documented a discussion of goals of care; this was more likely with residents using a template (83 % vs 11 %, $p=0.001$). Qualitative analysis results are pending.

CONCLUSIONS: This study assessed the impact of an educational intervention and EMR template on the content and quality of ACP documentation by IM residents. Regardless of template use, certain discussion elements such as HCP were addressed in nearly all ACP notes, while disease trajectory and prognosis were infrequently addressed. However, residents who used the template were significantly more likely to explore goals of care with patients. The limitations of this study are the lack of a control population who did not receive the curriculum and the small number of residents who opted to use the template. Analysis of the clinical usefulness of ACP documentation is still pending and

will identify characteristics of notes that are most helpful for future decision-making. Findings will contribute to future iterations of the resident curriculum to improve ACP communication and documentation skills.

Comparison of ACP discussion elements between templated and free-text notes

Discussion Elements	Template (n=6) n (%)	Free-Text (n=28) n (%)	P value
HCP discussed	6 (100)	27 (96.4)	1.00
HCP selected	5 (83.3)	19 (67.9)	0.64
HCP form scanned into EMR	3 (50)	16 (57.1)	1.00
HCP involved (or plan to involve) in ACP	3 (50)	13 (46.4)	1.00
Prognosis and/or disease trajectory discussed	1 (16.7)	7 (25)	1.00
Goals of care discussed*	5 (83.3)	3 (10.7)	0.001
Specific medical interventions discussed (including DNR) ^a	4 (66.7)	9 (32.1)	0.17
Out of hospital DNR order placed	1 (16.7)	3 (10.7)	0.56

* E.g. values, activities, fears, and prior experiences with illness. In the template, prompts include questions such as: "What is important to you in life? What activities or experiences are important for you to live well? What fears or worries do you have about your health?" ^ E.g. code status, artificial nutrition/hydration

ASSESSING LONG TERM OUTCOMES OF A TEACHING COMMUNICATION SKILLS COURSE FOR FELLOWS AND FACULTY Sarah B. Merriam; Robert M. Arnold; Carla Spagnoletti. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #1936910)

BACKGROUND: The ability to communicate effectively with patients is a key skill for practicing physicians. The importance of effective patient-doctor communication has received increasing attention in the field of medical education. Since 2003, the Clinician Educator Training Program at the University of Pittsburgh has offered a master's level course entitled "Teaching Communication Skills" designed to provide participants with the skills needed to effectively teach clinicians communication skills. This study's objective is to evaluate how this course influenced participants' subsequent teaching of communication skills and related scholarly endeavors.

METHODS: The 65 fellows and faculty who completed the "Teaching Communication Skills" course between 2003 and 2011 were surveyed electronically. The survey assessed participants' perceived importance and effectiveness of the course and its instructional methods. It also evaluated the use of these teaching skills in their current teaching practice. Demographic characteristics of the respondents as well as their career descriptions and academic productivity were assessed. Descriptive statistics were used to report survey responses.

RESULTS: A total of 53 of 65 course participants completed the survey (response rate 80 %). When asked why they took the course, 38 % indicated that it was highly recommended by peers and 85 % indicated that they anticipated a future role as a clinician educator and thought the course would be helpful in attaining this goal. Almost all (98 %) rated both the course and the individual communication-specific teaching skills taught in the course to be effective in the development of their teaching skills (on a 5-point Likert-type scale where 1 = ineffective and 5 = effective). When participants were asked to list which of the course's instructional methods were most beneficial in developing their ability to teach patient-doctor communication skills, most frequent responses included: exposure to the "primary teaching method" (a learner-centered small group facilitation method commonly used to teach communication skills; n=14), the process of direct observation and feedback (n=22), and small group role play with standardized patients (n=52). All instructional methods taught in the course were reported to be increasingly utilized in their teaching practice since taking the course, with 77 % using standardized patients, 89 % using small group work, and 83 % using role-play at least annually. Forty-nine (93 %) graduates described their current position as academic. Of those individuals, 72 % described roles as clinician-educators, 11 % as clinician-researchers, and 6 % as clinician-administrators. Since taking the course, 72 % of respondents have either developed or taught in a communication curriculum. Thirteen (25 %) have held a leadership or administrative position directly related to patient-doctor communication. Forty-four (83 %) have since pursued research or other scholarly activity related to communication: 10 obtained grant funding, 28 presented their work at a regional or national conference, and 21 wrote peer-reviewed manuscripts.

CONCLUSIONS: This novel course was highly rated by the fellows and faculty who participated. A majority of course participants went on to design or teach

communication curricula. Courses such as this one, designed to instruct educators how to teach communication skills, may be valuable to medical schools and other training programs that want to improve their faculty's ability to effectively deliver this curricular content to trainees.

ASSESSING PATIENT ATTITUDES AND PRACTICES REGARDING INFORMATION TECHNOLOGY IN A PATIENT CENTERED MEDICAL HOME: ARE WE READY FOR TELEMEDICINE? Jeanne Morley^{1,2}; Daniel J. Coletti^{1,2}; Laura Harrison¹; Joseph Conigliaro^{1,2}. ¹North Shore LIJ Health System, Great Neck, NY; ²Hofstra North Shore-LIJ School of Medicine at Hofstra University, Hempstead, NY. (Tracking ID #1936175)

BACKGROUND: Delivering care in a Patient Centered Medical Home (PCMH) requires an understanding of patient comfort with and access to information technology (IT), as use of that technology in the general population evolves and expands. According to a recent Pew Research Center report, 56 % of Americans owned a smartphone and 34 % used a tablet computer. Nearly 165 million Americans use social media, and as of 2012, one in three cell phone owners reported using their phones to look up health information. While email, text messaging, video chat, and social media have transformed how Americans communicate, most medical practices have failed to keep pace with these changes. Although about one third of Americans prefer getting text messages to phone calls and almost three quarters use email daily, the majority of physician offices still exclusively communicate by telephone with patients to make appointments, review lab results and answer questions. While clearly desirable, implementing new models of patient communication requires an understanding of patient access to technology. This is particularly salient in primary care settings that treat the underserved, who may lack access to novel and expensive forms of technology. The objectives of this investigation were to describe patient patterns of using IT in general, and to examine patient preferences and attitudes to using IT as part of their health care. We also wished to assess whether attitudes were associated with respondent age and sex.

METHODS: We completed a descriptive study as part of a larger feasibility study to prepare for deployment of internet-based patient communications within a large PCMH. The study was approved by our Institutional Review Board. We created a 12-item questionnaire entitled Patient Attitudes to Information Technology (PAIT) to assess the frequency of use of communication modalities such as email, text messaging, video chat, and attitudes towards IT. Our sample included patients seen for routine visits, complete physical exams, and sick calls during July and August of 2013. Questionnaires were completed in the office waiting room prior to a medical appointment. The office is a busy academic primary care practice, and designated Level III PCMH. Our patient population is diverse, and spans a wide range of educational and socioeconomic strata. Roughly half have Medicare or private insurance, and the other half are uninsured or have Medicaid. The questionnaire was offered to all patients on a voluntary basis. No protected health information was collected. Chi-square analyses, T-tests for independent means and Analysis of Variance (ANOVA) were deployed as appropriate to test for differences in attitudes according to demographic variables.

RESULTS: A total of 215 questionnaires were completed. Mean age of the sample was 48.29 years (SD=18.26, range=18–90) and was 62.5 % female. On the day of their visit, 50.7 % of the patients surveyed had already used a PC, 55.5 % had used email, 79.2 % made a mobile phone call, 59.9 % had sent or received a text message, and 18.6 % had used a video chat application. When assessment was expanded to the past week, the numbers increased to 78.4 %, 75.9 %, 91.5 %, 72.3 %, and 49.1 % respectively. Patients were also asked to score their agreement with four statements regarding IT on a scale of 0–10. On average, our patients reported moderate-to-high levels of agreement that they "have a lot of experience using smart phones" (mean = 6.01 out of 10), and were "the kind of person who like trying new electronic devices (mean = 6.86 out of 10). We also found high levels of agreement with the statement, "I would be interested in learning more about ways to use information technology... to communicate with my medical team," (M=7.0 out of 10). Although patterns of use and comfort with technology were high overall, statistically significant age-related effects were observed across all attitudinal variables ($p<.001$ for all analyses), with younger respondents more likely to express higher levels of comfort and interest in IT.

CONCLUSIONS: Results from this investigation suggest high levels of both readiness and interest among the patients in our PCMH to use IT to augment current communication with their medical team. Observed age-related effects suggest that older patients, while generally interested in using IT to facilitate healthcare communication, may need additional support to increase their knowledge and comfort level prior to implementing new forms of interaction with their healthcare

team. We were particularly surprised and encouraged by the frequent use of video-based applications among our respondents. Using this modality to facilitate more integrated care seems promising and realistic. Areas to explore could be more frequent but remote video monitoring of our high risk patients, extending the range of directly observed therapy, and support for patients involved in modification of high-risk behaviors, such as smoking cessation, ETOH reduction, and substance misuse.

ASSESSING THE IMPACT OF A RESIDENT COORDINATED TRANSITIONAL CARE ROTATION ON RESIDENT ATTITUDES TOWARDS PATIENT TRANSITIONS AND HEALTH MANAGEMENT Alexis Eastman^{1,3}; Elizabeth Chapman^{1,2}; Laury Jensen³; Holly I. Bottoms⁴; Mary Thompson²; Bennett Vogelman^{1,2}; Amy J. Kind^{2,3}. ¹University of WI Hospitals and Clinics, Madison, WI; ²University of Wisconsin, Madison, WI; ³Madison VA Geriatric Research Education and Clinical Center, Madison, WI; ⁴William S. Middleton Memorial Veterans Hospital, Madison, WI. (*Tracking ID #1938974*)

BACKGROUND: Although the Accreditation Council for Graduate Medical Education (ACGME) and others have called for improved medical resident education in the area of care transitions, few well-described formal education programs are available in the published literature to accomplish this goal. Pragmatically, instituting a formal transitions training program is challenging due to supervision and site-specific limitations and work hour requirements. Our objective was to evaluate whether Resident Coordinated Transitional Care (RC-TraC), an adaptation of the previously tested phone-based VA Coordinated Transitional Care (C-TraC) program, impacted resident attitudes related to transitional care.

METHODS: In 2009, the University of Wisconsin Internal Medicine residency program established RC-TraC, a phone-based care transitions training experience for residents randomly assigned to VA primary care continuity clinics. Residents with other primary care continuity clinics did not have a formal care transitions training experience. During this rotation, residents act as discharge care managers for hospitalized patients from the resident clinic panel, similar to the RN case manager position in the C-TraC program. Prior to discharge, the RC-TraC residents counsel patients on symptoms that should warrant medical attention. Post-discharge, the RC-TraC residents complete protocolized phone calls weekly for 30 days wherein symptoms are reviewed, medications reconciled and appropriate follow-up appointments are verified. In spring of 2013, all UW internal medicine residents were electronically surveyed to determine their attitudes regarding care transitions, including residents who did ($N=31$) and did not experience RC-TraC ($N=56$). Responses were collected on a 4-item modified Likert scale (almost never, infrequently, often, almost always). For purposes of analysis, "almost never/infrequently" and "often/almost always" were combined. Frequencies were compared using Chi-squared tests.

RESULTS: Overall survey response rate was 83/87 (95 %), with 29/31 (94 %) RC-TraC and 54/56 (96 %) non-RC-TraC residents responding. Ninety-seven percent of residents who had experienced RC-TraC at least once identified that they had received in-residency transitions training, while only 24 % of non-RC-TraC residents felt they had received transitions training ($p<0.001$). When compared to non-RC-TraC residents, RC-TraC residents were more likely to believe patients could "almost always/often" identify their pre-admission meds (45 % RC-TraC versus 18 % non-RC-TraC, $p=0.01$), identify their pre-admission diagnoses (55 % vs 35 %, $p=0.08$) and know how to contact providers post-discharge (52 % vs 31 %, $p=0.07$). Yet, there was no statistical difference between RC-TraC and non-RC-TraC residents' beliefs on patients' abilities to identify post-discharge medications and hospital diagnoses.

CONCLUSIONS: Findings suggest that the RC-TraC program is identified by residents as a formal care transitions training experience and that it alters resident perceptions of patients' baseline capacity for health management. This may suggest that RC-TraC increased residents' appreciation for a patient's capacity to participate in their health care. RC-TraC is a feasible care transitions training program, but needs additional testing of its impact on resident knowledge and patient outcomes.

ASSESSING THE UNDERSTANDABILITY AND ACTIONABILITY OF AFTER VISIT SUMMARIES FROM PRIMARY CARE CLINICS Alex Federman¹; Christopher Salmon¹; Ravishankar Ramaswamy¹; Sereena Singh¹; Allison L. Russell²; Michael S. Wolf². ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Feinberg School of Medicine, Northwestern University, Chicago, IL. (*Tracking ID #1936547*)

BACKGROUND: The after visit summary (AVS) is a document given to patients to summarize key elements of the clinical encounter. The AVS has the potential to serve

as an organizing and informational tool for patients, and has gained importance as new federal and state health policies, like Meaningful Use, work to advance patient centered care. Despite this, little is known about the AVSs currently in use in ambulatory practices. In this study, we sought to characterize the content and formatting of AVSs from a primary care practices and determine understandability and actionability of the information they provide.

METHODS: We identified National Committee for Quality Assurance (NCQA) accredited level III patient centered medical homes from the NCQA public use database and through snow-ball contacts. A convenience sample of these practices was contacted by email and telephone. Clinic directors or clinician representatives underwent a semi-structured interview about their experience with their practice's AVS and were asked to email or fax de-identified samples of actual AVSs from their practice. AVS samples were analyzed for content, length, and reading grade level. They were then assessed for understandability and usability using the Patient Education Materials Assessment Tool (PEMAT). Two raters independently evaluated the AVS samples.

RESULTS: We evaluated AVS documents from 18 primary care practices in 14 states. Number of pages ranged from 1 to 9 (median, 2) and the mean and median font size was 10. Content included medication lists (100 %), specific instructions and referrals requested or procedures performed (83 %), diagnoses (72 %), vital signs (67 %), allergies (56 %), appointments (50 %), goals of care (22 %), and immunization history (17 %). On the PEMAT, the average levels of understandability and actionability were 62 % and 80 %, respectively, indicating poor understandability and fair actionability. The median reading grade level was 12 (range 8–19) by the Flesch-Kincaid formula. Interviewed clinicians generally believed that their AVSs were of little use to patients except for the medication lists. None reported providing AVSs in languages other than English.

CONCLUSIONS: After visit summaries may not be achieving their intended purpose of providing patients with accessible and useful information regarding their care, nor meeting Meaningful Use requirements for content, even in NCQA-certified level III patient centered medical homes. Improvements in formatting, wording, and content of AVSs are needed to advance patient-centered care.

ASSESSMENT OF THE "SPEAKING UP" CULTURE: A NEW DOMAIN FOR PATIENT SAFETY CULTURE SURVEYS William Martinez¹; Jason M. Etchegaray²; Lisa Lehmann^{3,5}; Eric J. Thomas²; Sigall K. Bell^{1,5}. ¹Vanderbilt University Medical Center, Nashville, TN; ²University of Texas Medical School at Houston, Houston, TX; ³Brigham and Women's Hospital, Boston, MA; ⁴Beth Israel Deaconess Medical Center, Boston, MA; ⁵Harvard Medical School, Boston, MA. (*Tracking ID #1939052*)

BACKGROUND: Despite over a decade focusing on identifying the key components of patient safety culture relevant to healthcare settings, tangible safety progress has been slow. Current safety culture assessments fail to measure an important emerging competency, "speaking up" about patient safety threats, a skill that may be particularly challenging for residents responding to conforming pressures of the medical hierarchy. Thus, we sought to (1) develop and test survey items that measure the speaking up culture in the clinical work environment, (2) examine relationships among speaking up culture, teamwork culture, error disclosure culture and safety culture and (3) establish predictive validity for survey items measuring speaking up culture.

METHODS: All (667) surgical and medical residents from two large academic medical centers were invited to complete an anonymous, electronic questionnaire. The questionnaire asked respondents about personal experience speaking up about threats to patient safety, and contained six items developed by patient safety experts to assess the speaking up culture in the clinical environment. It also included previously validated measures of safety culture including the safety and teamwork dimensions of the Safety Attitudes Questionnaire (SAQ) and the general dimension of the Error Disclosure Scale. Factor analysis was used to test whether the six speaking up items were consistent with the concept of speaking up about threats to patient safety and to create a summary score in order to examine the relationship of speaking up culture to other patient safety domains and compare speaking up culture between groups.

RESULTS: The overall response rate was 52 % (349/667). Factor analysis supported a single 6-item speaking up scale and a scale score was created by summing the 5-point Likert-scale responses to individual items (score range: 5–30, Cronbach $\alpha=0.75$). Speaking up culture was a measure unique from safety culture, teamwork culture, and error disclosure culture scales (correlations less than $r=0.85$). Speaking up culture predicted residents' self-reported, personal experience speaking up about patient safety threats during their last inpatient month (OR 1.13, 95%CI 1.05–1.22), while teamwork (OR 1.02, 95%CI 0.91–1.15), error disclosure (OR 0.98, 95%CI 0.92–1.05) and safety culture (OR 0.96, 95%CI 0.92–1.01) did not. Surgical residents perceived their clinical work environment's culture to be less supportive of speaking

up than medical residents (mean scale score: 21.22 vs. 22.19, $P=0.045$). Compared to medical residents, fewer surgical residents felt (A) encouraged by colleagues to speak up about patient safety concerns (76 % vs. 62 %; $P=0.006$) and (B) that speaking up about patient safety concerns results in meaningful change (67 % vs. 55 %; $P=0.03$).

CONCLUSIONS: Our speaking up scale has sound psychometric properties and is a new measure of speaking up culture regarding patient safety threats in the clinical work environment that predicts self-reported speaking up about safety threats among residents. This measure fills an existing gap in assessments of organizational safety by measuring the extent to which the culture within a clinical work environment supports clear, direct, real-time communication between colleagues when a threat to patient safety is identified, a critical aspect of safety culture that is not currently assessed by traditional safety culture instruments. The culture may be less supportive of residents speaking up in surgical environments than in medical environments.

ASSOCIATION BETWEEN AFTER-VISIT CLINICAL SUMMARIES AND CHRONIC DISEASE MANAGEMENT

Rebecca G. Mishuris^{1,2}; Michael Healey^{1,2}; Endel J. Orav^{1,2}; Jennifer Haas^{1,2}. ¹Brigham and Women's Hospital, Boston, MA; ²Harvard Medical School, Boston, MA. (*Tracking ID #1937817*)

BACKGROUND: Electronic health records (EHRs) have been adopted by 72 % of US physicians. The Medicare and Medicaid EHR Incentive Program, or "meaningful use", incents physicians to adopt EHRs and perform certain tasks with them, including the provision of after-visit clinical summaries following every office visit. These summaries must at least contain the patient's problem list, medication list, allergies, and recent lab results. It is unknown how these visit summaries, and the written information they provide to the patient, will impact chronic disease management.

METHODS: We used patient data from 14 adult primary care clinics associated with a Boston teaching hospital from October 2010 to October 2013 to determine whether providing after-visit clinical summaries is associated with an improvement in diabetes management, as measured by hemoglobin A1c (HbA1c). After-visit clinical summaries were completely implemented across all clinics by October 2012, which was used as the cut-off time for pre- and post-implementation analysis. After-visit clinical summaries are provided to patients after every clinic visit, either in person, by mail or through an electronic patient portal. Patients were included in the analysis if they were 18 to 74 years of age, seen at one of the clinics at least once and were prescribed an anti-hyperglycemic agent for diabetes management during the period from October 2010 to October 2013. We will perform an interrupted time series analysis with repeated measures to look for a difference in change of HbA1c from the time prior to implementation of the after-visit clinical summaries to the time after the implementation of the after-visit clinical summaries. We will use clustering to account for the effect of the clinic or provider and control for patient characteristics, how the after-visit clinical summary was provided and the number of instances that the after-visit clinical summary was provided.

RESULTS: There were 6935 patients in this cohort; 6281 patients were seen prior to the implementation of the after-visit clinical summary and 5414 patients were seen after the implementation of the after-visit clinical summary. As of October 2013, 94.8 % of physicians were meeting the meaningful use requirement of providing after-visit clinical summaries for greater than 50 % of clinic visits, and patients were provided an after-visit clinical summary for 84.8 % of all clinic visits. Average HbA1c prior to implementation was 7.7, ranging from 3.8 to 18.9. Average change in HbA1c during this period was -0.03, ranging from -12.2 to 13.3. Average percentage change in HbA1c during this period was 1.6 %, ranging from -64.5 to 97.0 %. Average HbA1c after implementation was 7.7,

ranging from 4.1 to 18.9. Average change in HbA1c during this period was 0.06, ranging from -13.1 to 8.8. Average percentage change in HbA1c during this period was 3.8 %, ranging from -69.3 to 85.0 %. The study will have a power of 80 % to detect a 0.05 change in HbA1c with 95 % confidence and a power of 95 % to detect a 0.1 change in HbA1c with 95 % confidence.

CONCLUSIONS: After-visit clinical summaries have been successfully implemented in our adult primary care clinics. Average hemoglobin A1c control has not changed from the period preceding implementation of these patient after-visit clinical summaries to the period following implementation. Further analysis is required to determine whether there has not yet been a long enough follow-up period to see a significant change in chronic disease control associated with after-visit clinical summaries or whether there needs to be further emphasis placed on the importance of the information provided in the after-visit clinical summary to effect a change in chronic disease control.

ASSOCIATION BETWEEN BMI AND QUALITY OF CARE AMONG INDIVIDUALS WITH HIV, 2007–2010

Erin Fenner¹; Somnath Saha¹; Stephen Berry²; Rochelle Fu¹; Baligh Yehia³; Kelly Gebo²; Allison Agwu²; Philip T. Korthuis¹. ¹Oregon Health and Science University, Portland, OR; ²Johns Hopkins University School of Medicine, Baltimore, MD; ³University of Pennsylvania, Philadelphia, PA. (*Tracking ID #1940304*)

BACKGROUND: Prior studies suggest health care providers harbor biased attitudes toward obese patients, which could affect the quality of care received. HIV providers are increasingly encouraged to adhere to quality indicator (QI) performance measures. We sought to assess differences in the care provided to HIV patients by BMI category.

METHODS: We abstracted nine HIV QIs (Table) from medical records of 6,031 patients (10,896 total person-years) age >18 years engaged in care (≥ 2 clinic visits per calendar year) at seven clinics in the HIV Research Network between 2007 and 2010. Underweight patients were excluded. Patient BMI was categorized as normal (18.5 \leq 24.9), overweight (25 to 29.9), stage 1 obese (30 to 34.9), stage 2 obese (35 to 39.9), and stage 3 obese (≥ 40). Using generalized estimating equations, logistic regression examined the association between BMI and receipt of each QI, and linear regression examined associations between BMI and the mean percent of QIs received, adjusting for age, race, sex, HIV risk behavior, and number of primary care visits in a year. We used R-squared to assess linear trends in odds ratios (ORs) and beta coefficients across BMI category.

RESULTS: Overall, patients received 65 % of eligible QIs in a given year. Those with stage 3 obesity received slightly lower eligible QIs vs. normal weight patients (64.3 % vs. 65.7 %, adjusted $\beta=-0.04$, 95 % CI -0.06, -0.02), with a moderate downward linear trend as BMI increased ($R^2=0.691$). With regard to specific QIs, patients with stage 3 obesity received less screening for gonorrhea/Chlamydia (GC) (aOR=0.76, 95 % CI 0.60 to 0.96) and syphilis (aOR=0.69, 95 % CI 0.56 to 0.86) relative to normal weight patients. As BMI category increased, linear trends were observed for decreasing syphilis, GC, and HCV screening, and increasing CD4 count monitoring and lipid screening (Table). Receipt of ART, PCP and MAC prophylaxis were comparable across BMI categories.

CONCLUSIONS: Overall, HIV quality of care differed only slightly across BMI categories. Providers prescribed ART regardless of BMI, but performed less sexually transmitted infection screening and more lipid screening as BMI increased, suggesting providers may consciously or unconsciously prioritize some QIs over others in patients with higher BMI. Additional studies are needed to determine the source of these differences.

Adjusted Associations Between BMI Category and Receipt of each QI and Mean Percent QI Received, if Eligible.

	Normal Weight	Overweight	Stage 1 Obese	Stage 2 Obese	Stage 3 Obese	Test of Trend (R2)
Mean% QIs Received	65.7 % $\beta=$ 0.00 – 0.00	65.8 % $\beta=-0.01$ (-0.02, -0.02, 0.00)	65.8 % $\beta=-0.01$ (-0.02, 0.00)	65.8 % $\beta=-0.02$ (-0.03, 0.00)	64.3 % $\beta=-0.04$ (-0.06, -0.02)	0.69
≥ 2 CD4 Counts	OR=1.0 –	OR=1.20 (1.04, 1.37)	OR=1.12 (0.93, 1.35)	OR=1.08 (0.83, 1.42)	OR=1.44 (1.07, 1.95)	0.53
ART Therapy	1.0 –	OR=0.90 (0.72, 1.12)	OR=1.08 (0.80, 1.46)	OR=1.23 (0.80, 1.90)	OR=0.80 (0.50, 1.30)	0.00
PCP Prophylaxis	1.0 –	OR=0.65 (0.46, 0.92)	OR=0.63 (0.39, 1.02)	OR=0.79 (0.41, 1.53)	OR=1.45 (0.40, 5.22)	0.24
MAC Prophylaxis	1.0 –	OR=0.76 (0.41, 1.40)	OR=0.81 (0.34, 1.88)	OR=1.65 (0.51, 5.34) (combined for small n)	0.39

ASSOCIATION BETWEEN EMERGENCY DEPARTMENT USE AND THE DISCRIMINATION PERCEIVED BY FREQUENT USERS Stéphanie Baggio¹; Patrick Bodenmann²; Jean-Bernard Daepen²; Bernard Burnand²; Olivier Hugli²; Ornella Ruggeri²; Jean-Blaise Wasserfallen²; Karine Moschetti²; Philippe Staeger²; Séverine Alary²; Katia Iglesias²; Marina Canepa Allen². ¹Lausanne University, Lausanne, Switzerland; ²Lausanne University Hospital, Lausanne, Switzerland. (*Tracking ID #1930263*)

BACKGROUND: Frequent Emergency Department (ED) users are often vulnerable patients with many risk factors. Furthermore, they are often perceived as unwelcome patients, causing EDs' overcrowding, and being time-consuming, "illegitimate" users. However, data are scarce regarding how frequent ED users deal with this perception and particularly regarding their related feelings of discrimination. This study investigated the relationship between frequent ED use and perceived discrimination during such use in Switzerland.

METHODS: Data were part of a baseline assessment of a randomized controlled trial designed to improve frequent users' quality of care in Lausanne University Hospital, a French-speaking Swiss tertiary care hospital, with over 50,000 annual ED visits. In total, 250 frequent ED users (≥ 5 attendances during the previous 12 months, ≥ 18 years), were interviewed between May 2012 and July 2013. From a previously published questionnaire, 15 dichotomous sources of discrimination were assessed, and grouped into five dichotomous causes: (i) any cause, (ii) immigration-related, (iii) age/gender, (iv) physical characteristics/sexual orientation, (v) social/economic status. Prevalence rates of perceived discrimination were computed first, then associations between the number of ED attendances and perceived discrimination were assessed with multivariate models (logistic regressions) controlling for socio-demographic characteristics and health-related issues (i.e. age, gender, education, nationality, proficiency in French, health literacy, and somatic-, mental-health-, behavioral-, and social issues).

RESULTS: Participants were 46.2 ± 18.9 years old on average, 57.2 % were men, 47.8 % Swiss, 17.7 % European, and 34.5 % non-European. In total, 11.6 % of the frequent ED users were asylum seekers or undocumented immigrants. Prevalence rates of perceived discrimination showed that 35.2 % reported at least one source of discrimination. Discrimination related to physical characteristics/sexual orientation (20.8 %), social/economic position (16.0 %), and immigration (16.0 %) was more frequent than discrimination related to age and gender (6.8 %). Multivariate models showed that when the number of ED visits increased, frequent users were more likely to feel discriminated against (any cause: odd-ratio [OR]=1.19, $p=0.023$), particularly regarding social/economic status (OR=1.28, $p=0.011$) and physical characteristics/sexual orientation (OR=1.19, $p=0.023$). Contrariwise, discrimination related to immigration and age/gender was not significantly related to the number of ED attendances ($p=.803$ and $p=0.266$).

CONCLUSIONS: Frequent ED users appeared to perceive frequent discrimination (35.2 % compared to 11.1 % of non-frequent ED users hospitalized in another French-speaking Swiss tertiary hospital), associated with an increased number of ED attendances. Moreover, they did not feel discriminated against due to intrinsic characteristics or race-based sources (e.g. age, gender, nationality, or skin color), but rather for social and lifestyle factors (e.g. income, education, physical appearance, or sexual orientation), even if foreigners, asylum seekers, and undocumented immigrants were highly represented in the sample. The conclusions of this study should help health care practitioners and managers to be more cautious about potential discrimination against frequent ED users, as they may be unwittingly perpetuating health care disparities.

ASSOCIATION BETWEEN OFFICE-BASED MEDICAID ACCEPTANCE RATES AND SAFETY-NET SERVICE UTILIZATION BY MEDICAID PATIENTS Kimberly Cartmill; Arnab K. Ghosh; Meroe B. Morse; Shawn L. Tyler. New York University, New York, NY. (*Tracking ID #1929579*)

BACKGROUND: The Patient Protection and Affordable Care Act (ACA) expands Medicaid coverage, which may increase utilization of healthcare safety net facilities such as emergency departments (EDs) and hospital outpatient departments (OPDs). To ease their burden, the ACA raises Medicaid reimbursement rates to encourage primary care physicians to accept Medicaid patients. It is uncertain if an increase in outpatient Medicaid acceptance rates is associated with a decrease in hospital OPD and ED visits among Medicaid patients. This study uses a robust national survey to determine the association between office-based Medicaid acceptance rates and the percent of Medicaid OPD and ED visits.

METHODS: Data from two nationally representative surveys, NAMCS and NHAMCS, were used to measure Medicaid acceptance rates among office-based

physicians and percent of Medicaid ED and OPD visits from 2003 to 2010. 231,000 physicians responded to NAMCS. 269,000 OPD visits and 257,000 ED visits were used in NHAMCS. Trends in acceptance rates and percent Medicaid OPD and ED visits were analyzed by year (2003–2010) and across four broad census regions covering the country. Thirty-two point estimates, each representing one region and 1 year, were used to test the relationship between office-based acceptance rates (NAMCS) and hospital-based visits (NHAMCS). Pearson's correlation coefficient was applied to assess magnitude, direction and significance of the association.

RESULTS: Response rates for the specified questions studied were 97 % for acceptance rates; 94 % for expected method of payment for OPD or ED visits. Nationally, no statistically significant trend in percent of office-based physicians accepting Medicaid was found (adjusted F 2.16, $p=0.62$) between 2004 and 2010 (2003 excluded as outlier). These rates did not differ by year within three of the four regions. Percent Medicaid, OPD, and ED visits did not change significantly over the 7-year period nationally or within regions. When Medicaid acceptance rates were compared with percent Medicaid ED visits using point estimates, there was no significant correlation ($R^2=0.05$; $p=0.87$). However, there is a strong negative correlation between percent office-based Medicaid acceptance and percent Medicaid OPD visits ($R^2=-0.59$, $p<0.01$).

CONCLUSIONS: In nationally representative data sets, office-based physician acceptance rates of Medicaid patients were inversely associated with visits to hospital outpatient departments, but not hospital emergency departments. Hospital outpatient departments may serve as a buffer to prevent emergency department utilization. This requires further investigation with better national surveys to assess the impact of health policy interventions.

ASSOCIATION BETWEEN OUTPATIENT "NO-SHOWS" AND SUBSEQUENT ACUTE CARE UTILIZATION Andrew S. Hwang¹; Steven J. Atlas²; Patrick R. Cronin³; Jeffrey M. Ashburner²; Sachin J. Shah²; Wei He²; Clemens S. Hong². ¹Tufts University School of Medicine, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Massachusetts General Hospital, Boston, MA. (*Tracking ID #1934637*)

BACKGROUND: To reduce healthcare costs, healthcare systems are focusing on identifying the relatively small percentage of patients who account for a disproportionate share of hospitalizations and emergency department (ED) visits. We hypothesized that primary care patients with a higher propensity for missed outpatient appointments, or "no-shows," will have higher acute care utilization over the following 3 years.

METHODS: We calculated the "no-show propensity factor" (NSPF) for 140,947 patients seen in an academic primary care practice network from 2007 to 2009 using 5 years (2005–2009) of outpatient appointment data. NSPF transforms a patient's count of arrivals and no-shows into a score that represents appointment adherence, correcting for patients with few appointments to avoid undue influence on the model. We divided patients into two groups: patients in the highest quartile and patients in the lower 3 quartiles of NSPF, and assessed subsequent hospital and ED utilization over 3 years (2010–2012). We evaluated the association between NSPF and our two continuous outcomes using Poisson regression models adjusting for number of outpatient visits in 5 years (2005–2009). Using a "change-in-estimate" strategy, we included other patient characteristics (age, gender, race, language, insurance, neighborhood median household income, Charlson comorbidity index, diagnosis of depression and alcoholism, and hospitalization and ED visits in 2009) and primary care provider characteristics (gender, years in practice, and whether the provider practiced at a community health center) in the models if they altered the incidence rate ratio (RR) by >5 %. We also ran models adjusting for all patient and provider characteristics and performed a subgroup analysis to examine the association between NSPF and subsequent hospitalization in patients with high-risk chronic illnesses (congestive heart failure, chronic obstructive pulmonary disease, diabetes mellitus, atrial fibrillation, coronary artery and cerebrovascular disease).

RESULTS: Compared to patients in the lower 3 quartiles of NSPF, patients in the highest quartile were significantly ($P<0.001$ for all) younger (45 vs. 52 years) and more likely to be male (44 % vs. 42), non-white (37 % vs. 16 %), non-English speaking (17 % vs. 6 %), and insured by Medicaid or uninsured (22 % vs. 9 %), live in neighborhoods with low median household income (\$50,612 vs. \$63,781) and have higher rates of ED visits (192 vs. 84 visits/1,000 patients) and admissions (94 vs. 68 hospitalizations/1,000 patients) in 2009. In the subsequent 3 years (2010–2012), patients in the highest quartile of NSPF had significantly ($p <.0001$ for all) higher unadjusted rates of acute care utilization (77 vs. 66 hospitalizations/1,000 patients/year and 153 vs. 73 ED visits/1,000 patients/year) than patients in the lower 3 quartiles. In addition, Poisson regression analysis

demonstrated that compared to patients in the lower 3 quartiles of NSPF, eligible patients in the highest quartile had a 19 % increased rate of ED visits in 3 years (adjusted RR 1.19 [1.05–1.34] adjusting for number of outpatient visits, age and ED visits and hospitalizations in 2009), but not a significantly increased rate of hospitalization in 3 years (adjusted RR 1.08 [0.996–1.18] adjusting for number of outpatient visits, age, and ED visits in 2009). Including all variables in the regression models did not change the significance or direction of the findings, and subgroup analysis among patients with high-risk comorbidities (congestive heart failure, chronic obstructive pulmonary disease, diabetes mellitus, atrial fibrillation, coronary artery and cerebrovascular disease) did not reveal a significant association between NSPF and hospitalization.

CONCLUSIONS: NSPF was an independent predictor of subsequent ED utilization. Using NSPF may help primary care delivery systems identify patients at increased risk for frequent utilization of the ED and tailor programs to increase primary care engagement and reduce ED overutilization.

ASSOCIATION BETWEEN OUTPATIENT “NO-SHOWS” AND SUBSEQUENT CLINICAL OUTCOMES

Andrew S. Hwang¹; Steven J. Atlas²; Patrick R. Cronin³; Jeffrey M. Ashburner²; Sachin J. Shah²; Wei He²; Clemens S. Hong².

¹Tufts University School of Medicine, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Massachusetts General Hospital, Boston, MA. (*Tracking ID #1934608*)

BACKGROUND: To improve care and achieve performance targets, healthcare systems seek to identify patients at high risk for not achieving preventive cancer screening and chronic disease management goals. We hypothesized that patients with a higher propensity for missed outpatient appointments, or “no-shows,” would have lower colorectal cancer (CRC) screening and low-density lipoprotein (LDL) goal attainment over the following year.

METHODS: We calculated the “no-show propensity factor” (NSPF) for 140,947 patients seen in an academic primary care practice network from 2007 to 2009 using 5 years (2005–2009) of outpatient appointment data. NSPF transforms a patient’s count of arrivals and no-shows into a score that represents appointment adherence, correcting for patients with few appointments to avoid undue influence on the model. We divided patients into two groups: patients in the highest quartile and patients in the lower 3 quartiles of NSPF, and assessed CRC screening completion among patients (52–75 years) without prior colectomy and LDL goal ($LDL < 100 \text{ mg/dL}$) attainment in patients with diabetes or coronary artery disease at 1 year follow-up (2010). We evaluated the association between NSPF and our binary outcomes using logistic regression adjusting for number of visits. Using a “change-in-estimate” strategy, we included patient characteristics (age, gender, race, language, insurance, neighborhood median household income, Charlson comorbidity index, and diagnosis of depression or alcohol use disorder) and primary care provider characteristics (gender, years in practice, and whether the provider practiced at a community health center) in the models if they altered the odds ratio by $>5\%$. We also ran models adjusting for all variables.

RESULTS: Compared to patients in the lower 3 quartiles for NSPF, patients in the highest quartile were significantly ($P < 0.0001$ for all) younger (45 vs. 52 years) and more likely to be male (44 % vs. 42), non-white (37 % vs. 16 %), non-English speaking (17 % vs. 6 %), lack insurance (7 % vs. 4 %), live in neighborhoods with low median household income (\$50,612 vs. \$63,781), receive primary care at a community health center (15 % vs. 7 %), have a diagnosis of depression (20 % vs. 11 %) or alcohol use disorder (3 % vs. 1 %), and have higher number of outpatient visits over 5 years (27 vs. 21). Compared to eligible patients in the lower quartiles for NSPF, eligible patients in the highest quartile were significantly more likely to have not completed CRC screening (adjusted OR 1.87 [1.77–1.97] adjusting for number of visits and neighborhood median household income). Compared to patient in the lower quartile for NSPF, eligible patients in highest quartile were significantly more likely to have an above goal LDL (adjusted OR 1.70 [1.57–1.83] adjusting for number of visits and age). Inclusion of all variables in the models did not change the significance or direction of the effect, and the effect changed by less than 6 % for both outcomes.

CONCLUSIONS: NSPF was a strong, independent predictor of subsequent colonoscopy completion and LDL goal attainment. Using NSPF may help healthcare systems identify patients at increased risk for non-adherence to recommended care for targeted interventions to improve care and achieve performance targets.

ASSOCIATION BETWEEN USUAL SOURCE OF CARE AND CHRONIC DISEASE HOSPITALIZATION IN CALIFORNIA MEDICAID PATIENTS

Hugo A. Torres¹; Ed Yelin². ¹Cambridge Health Alliance, Cambridge, MA;

²University of California, San Francisco, San Francisco, CA. (*Tracking ID #1938741*)

BACKGROUND: The costs of Medicaid are driven in large part by the prevalence and costs of chronic diseases. Therefore, achieving improved control of chronic diseases by reducing the rates of hospital use associated with them is vital to the future successful expansion of the Medicaid program. Prior research links primary care access, often measured by usual source of care (USOC), with lower rates of hospitalizations for many chronic diseases, called ambulatory care sensitive Conditions (ACSC). Medicaid patients in general have high rates of ER utilization and hospitalization for ACSC relative to the uninsured and privately insured. This study aims to determine if the difference in ACS hospitalizations between Medicaid beneficiaries and low-income privately-insured individuals can be explained by the presence of a USOC.

METHODS: This is a cross-sectional study utilizing the 2009 and 2011 California Health Interview Survey (CHIS). The population studied is respondents to the CHIS, aged 18–64, earning less than 300 % of the Federal Poverty Level ($N=7564$). The principal independent variable is Medicaid vs. Private insurance. The outcome is an ED visit or hospitalization for an ACSC. We use logistic regression to control for demographic variables that have been previously shown to affect health access. The analysis determines if Medicaid insurance was associated with rates of ED use or hospitalization; USOC was added to the model, first as an independent variable, then as an interaction term, to determine if the magnitude of the effect of insurance status on chronic disease ED use or hospitalization was altered by primary care access.

RESULTS: Medicaid patients were likelier to be female (60 % vs. 53 %), younger (mean age 43.6 vs. 45.1), in poorer self-rated health, unmarried, and more likely to have children than their counterparts with private insurance ($p < 0.05$ for all comparisons). They were also more likely to report a disability and to lack a usual source of care (OR = 0.72, 95 % CI 0.54–0.95, $p = 0.02$). The unadjusted rates of ED use and hospitalization for ACS conditions were 46.8 % vs. 30.9 % for privately insured patients (OR: 1.96, 95 % CI 1.60–2.41, $p < 0.0001$). The OR adjusted for the above was lower but still significant at 1.54 (95 % CI 1.2–2.0, $p < 0.0001$). The association remained after controlling for USOC (OR 1.55, $p < 0.0001$). An interaction term for USOC and Medicaid was positive and significant (OR 1.79, $p = 0.05$), indicating an increased effect of Medicaid on ED use/hospitalization for ACS conditions.

CONCLUSIONS: This analysis demonstrates a correlation between Medicaid (vs. private) insurance and ED use/hospitalization among people with ACSC, and that possession of primary care access in the form of having a usual source of care did not affect this relationship in the expected pattern; in fact, having a usual source of care increased the association. This is consistent with data from Oregon that found increased primary care use and ED use among Medicaid patients. The explanation for this relationship is likely complex. Medicaid patients may face hardship to access their provider, and are also likelier to have mental health and social issues which complicate their care. This research highlights the need for expanded efforts to understand and treat the causes of poor chronic disease outcomes in Medicaid patients. To do so would be to improve their health status outcomes, decrease ED visits and hospitalizations, and improve quality of life.

ASSOCIATION OF ADHERENCE MEASURES WITH PHYSICAL ACTIVITY OUTCOMES IN AN ONLINE WEIGHT LOSS TRIAL: RESULTS FROM THE OCELOT STUDY

Bethany Scanlan; Molly B. Conroy; Dana L. Tudorascu; Irina Karpov; Rachel Hess; Gary Fischer; Laurey R. Simkin-Silverman; Kathleen M. McTigue. University of Pittsburgh, Pittsburgh, PA. (*Tracking ID #1931481*)

BACKGROUND: Lifestyle programs for weight loss and physical activity (PA) promotion have traditionally been delivered in person. Adherence, defined by number of sessions attended, has been shown to correlate with weight loss and PA improvements. With growing use of health information technology, an understanding of adherence to online interventions and the relationship between adherence and PA is needed. We hypothesize that participants adherent to an online intervention will have higher PA levels at 6 and 12 months than those who are non-adherent.

METHODS: The Online Counseling to Enable Lifestyle-focused Obesity Counseling in Primary Care (OCELOT-PC) study is a comparative effectiveness study of three online lifestyle interventions. We recruited 373 primary care patients, 257 of whom were randomized to a 12-month structured online adaptation of the Diabetes Prevention Program’s lifestyle intervention. The remaining patients had access to online resources alone and served as an active control arm. The behavioral online intervention included: lessons; self-monitoring (SM) of weight, eating pattern, and PA; feedback from a lifestyle coach; and links to community resources. We defined a current program user as a participant with a log-in in past 28 days. Non-users are those with no log-in for ≥ 28 days and no response to either of two weekly phone calls from the coach (initiated after the participant has not logged in for ≥ 14 days).

Adherence was also based on other aspects of program use including: log-in in past week, weight entered in past week, eating pattern and PA SM (including number of days of SM in past week), and number of lessons completed. PA was determined by steps recorded on a pedometer worn for 2 weeks at baseline, 6 months, and 12 month. Adherence measures were correlated with PA outcome using Pearson correlations for continuous variables; means were compared using t-tests.

RESULTS: We were able to calculate program use and other adherence measures for 255 participants who were given access to the structured online intervention. Eighty percent of participants were women, 77 % white, and 62 % had education \geq college; participants' average age was 49.2 years. Participants had an average (SD) of 4127 (1918) steps per day and weight of 107.1 (21.6) kg at baseline. At 6 months, patients who were current program users had a mean (SD) of 3955 (2467) steps per day; those who were non-users had a mean of 1888 (1930) steps ($p < 0.0001$). Those with a log-in in the past week, weight entered in the past week, or any diet or PA SM in the past week also showed statistically significant greater numbers of steps per day compared to those who were non-adherent to these measures (all $p < 0.001$). Number of lessons completed, mean number of days of dietary SM in past week, and mean number of days of PA SM in past week were positively correlated with PA ($r = 0.4$; $r = 0.37$; $r = 0.39$; all $p < 0.0001$). Similar trends were observed for PA at 12 months. At 12 months, current program users had a mean (SD) of 4384 (2755) steps; non-users had a mean of 2689 (2348) steps ($p < 0.001$).

CONCLUSIONS: Participant adherence to the online intervention was associated with PA outcome. Those who were adherent to the tasks of the behavioral online intervention had significantly more steps at 6 and 12 months compared to those who were non-adherent. Further research should focus on which measure of adherence best relates to PA and other behavioral outcomes, as well as mechanisms to increase adherence to online interventions.

ASSOCIATION OF CARDIOVASCULAR HEALTH SCREENING WITH MORTALITY, CLINICAL OUTCOMES, AND HEALTH CARE COST *Dong Wook Shin¹; Hyejin Lee¹; BeLong Cho¹; Juhee Cho²; Ju Young Kim¹; Eliseo Guallar². ¹Seoul National University Hospital, Seoul, Republic of Korea; ²Bloomberg school of public health, Baltimore, MD. (Tracking ID #1939911)*

BACKGROUND: Since several CVD risk factors are modifiable, prevention programs routinely screen for hypertension, diabetes, and dyslipidemia expecting that early detection and treatment of CVD-related health conditions will decrease the burden of CVD. The effectiveness of screening programs for the CVD-related health conditions on health outcomes and healthcare utilization, however, is unclear. In South Korea, a country with universal healthcare coverage, the Korean National Health Insurance (KNHI) Corporation provides a biennial CVD health screening program to all national health insurance members over 40 years of age free of charge. We aimed to determine whether a nationwide CVD health screening program is associated with CVD incidence, mortality, healthcare utilization and costs.

METHODS: We randomly selected a 3 % sample ($n=621$ 350) of all KNHI members 40 years of age or older as of December 31, 2002. We excluded participants with cancer, diabetes, hypertension, dyslipidemia, or any related CVD including stroke and myocardial infarction ($n=170$ 490). Study participants were followed-up from January 1, 2005 through December 31, 2010. Propensity score matching was used to improve comparability of screened and non-screened participants. ($n=149$ 243 matched pairs)

RESULTS: The hazard ratios for CVD mortality, all-cause mortality, and incident myocardial infarction, cerebral infarction, and cerebral hemorrhage during comparing participants who attended a screening exam during 2003–2004 compared to those who did not were 0.55 (95 % CI: 0.50–0.60), 0.63 (95 % CI: 0.61–0.66), 0.85 (95 % CI: 0.76–0.95), 0.82 (95 % CI: 0.77–0.87), and 0.71 (95 % CI: 0.65–0.79). Screening attenders had higher rates of newly diagnosed hypertension and dyslipidemia ($p < 0.001$), lower inpatient days of stay and cost and lower outpatient cost compared to non-attenders.

CONCLUSIONS: CVD health screening was associated with lower rates of CVD and all-cause mortality and CVD events, higher detection of CVD-related health conditions, and lower healthcare utilization and costs. In the absence of large randomized controlled trials, our findings are suggestive of the effectiveness of CVD screening programs.

ASSOCIATION OF ILLNESS BELIEFS AND END-OF-LIFE TREATMENT PREFERENCES AMONG LUNG CANCER PATIENTS *Jenny J. Lin; Jessica Lake; Juan Wisnivesky. Icahn School of Medicine at Mount Sinai, New York, NY. (Tracking ID #1939176)*

BACKGROUND: Patient preferences about end of life care regarding resuscitation and intubation may be influenced by illness beliefs, family/social factors or physician communication. We assessed the association between patient-physician communication and cultural beliefs with patients' preferences for end-of-life care among recently-diagnosed lung cancer patients.

METHODS: Patients with recently-diagnosed lung cancer were recruited from four medical centers in New York City from 2008 to 2011. Participants were surveyed about beliefs regarding lung cancer and cancer treatment, fatalism, medical mistrust and physician communication regarding treatment, symptoms and needs. Univariate analysis was used to assess which factors were associated with end-of-life preferences.

RESULTS: Of the 352 lung cancer patients enrolled in the study, 168 (48 %) were men; 21 % were black, 20 % were Hispanic and 59 % were white. Overall, 132 (38 %) did not want to be intubated and 88 (25 %) did not want to be resuscitated. Approximately 30 % of the participants did not have a preference regarding either intubation or resuscitation. Overall, 93 % of patients who did not want resuscitation also did not want intubation, while 25 % patients who wanted to be resuscitated did not want to be intubated. Those who were younger or who had lower educational attainment were more likely to want more aggressive care (resuscitation and intubation, $p < 0.05$ for all comparisons). There was no difference in end-of-life care preferences by lung cancer stage ($p > 0.05$ for all comparisons). Patients who believed that CPR should always be performed and those who expected their cancer to be cured were more likely to want aggressive care (both resuscitation and intubation, $p < 0.04$ for all comparisons). Additionally, those who agreed with the statement that "everything that happens is part of God's plan" ($p < 0.01$) or who believed there was a >50 % of restarting the heart when in cardiac arrest ($p = 0.03$) were more likely to want resuscitation. Patients who reported that their physicians discussed issues regarding life sustaining treatment were less likely to want resuscitation, whereas those who reported that their physicians talked about emotional symptoms were more likely to want more aggressive care ($p < 0.01$ for all comparisons).

CONCLUSIONS: Lung cancer patients' beliefs about cancer curability, resuscitation efficacy and fatalism impact their preferences about intubation and resuscitation. Physician discussions about life sustaining treatment may facilitate decisions about end-of-life preferences. Clinicians should ensure open conversations about patient beliefs about cancer prognosis and end-of-life care when discussing lung cancer treatment.

ASSOCIATION OF INFLUENZA VACCINATION COVERAGE IN YOUNGER ADULTS WITH INFLUENZA ILLNESS IN THE ELDERLY *Glen Taksler¹; Michael B. Rothberg¹; David M. Cutler^{2,3}. ¹Cleveland Clinic, Cleveland, OH; ²Harvard University, Cambridge, MA; ³National Bureau of Economic Research, Cambridge, MA. (Tracking ID #1928183)*

BACKGROUND: Older adults suffer the majority of influenza morbidity and mortality, but influenza vaccine effectiveness declines with age. It is unknown whether vaccination of nonelderly adults confers additional disease protection upon the elderly.

METHODS: Using the Behavioral Risk Factors Surveillance System Survey, we estimated countywide influenza vaccination coverage among adults aged 18–64 year in 313 counties comprising 56.5 % of the US population, in each influenza season (Oct–May) of 2002–2010. We linked these data with all Medicare claims for a random sample of 3,090,857 beneficiaries aged ≥ 65 y residing in these counties, and identified seasonal influenza-like illness (ILI) in each individual during the same years ($N=11,331,129$ person-years). Using ICD-9 codes, we identified four types of ILI, from most specific to least specific definition: influenza (primary diagnosis), influenza (primary or secondary diagnosis), pneumonia or influenza, and broader ILI including pneumonia, influenza, bronchitis, cough, or upper respiratory infection. Using logistic regression models, we examined the association between countywide vaccine coverage among adults aged 18–64 year and diagnosis of ILI in Medicare beneficiaries, adjusting for comorbidity, influenza season severity, demographics, countywide health and socioeconomic variables, and dummy variables for influenza season and state of residence. We repeated the analysis for hospitalizations for ILI. Results were stratified by documented receipt of a seasonal influenza vaccine in each Medicare beneficiary. An adjusted odds ratio (AOR) for influenza diagnosis in the elderly that varied inversely with vaccine coverage among nonelderly adults would suggest herd immunity. Additionally, we expected to observe a lower AOR with more specific definitions of ILI than with less specific definitions, and during peak (Dec–Mar) vs. non-peak (Oct–Nov, Apr–May) months of influenza season.

RESULTS: Increases in countywide vaccine coverage among 18–64 year-olds were associated with lower adjusted odds of influenza-like illness in the elderly. Compared

with elderly residents of counties with $\leq 15\%$ of 18–64 year-olds vaccinated, the AOR for a primary diagnosis of influenza was 0.90 (95 % CI=0.87–0.94) for elderly residents of counties with 16 %–20 % of 18–64 year-olds vaccinated, 0.84 (95 % CI=0.81–0.88) for elderly residents of counties with 21 %–25 % of 18–64 year-olds vaccinated, 0.78 (95 % CI=0.74–0.82) for elderly residents of counties with 26 %–30 % of 18–64 year-olds vaccinated, and 0.77 (95 % CI=0.73–0.81) for elderly residents of counties with $\geq 31\%$ of 18–64 year-olds vaccinated (P for trend <0.001). Weaker associations were observed for less specific definitions of influenza; elderly residents of counties with $\geq 31\%$ of 18–64 year-olds vaccinated had an AOR of 0.78 (95 % CI=0.74–0.81) for a primary or secondary diagnosis of influenza, 0.96 (95 % CI=0.95–0.98) for pneumonia or influenza, and 0.95 (95 % CI=0.94–0.96) for the broader definition of ILI, compared with elderly residents of counties with $\leq 15\%$ of 18–64 year-olds vaccinated. The association was stronger among vaccinated elderly (AOR for primary influenza in counties with $\geq 31\%$ vs. $\leq 15\%$ of 18–64 year-olds vaccinated = 0.63, 95 % CI=0.59–0.68) than for unvaccinated elderly (AOR=0.84, 95 % CI=0.79–0.89) (P for difference < 0.001). The association was also stronger in peak months (AOR for primary influenza in counties with $\geq 31\%$ vs. $\leq 15\%$ of 18–64 year-olds vaccinated = 0.75, 95 % CI=0.70–0.79) than in non-peak months (AOR=0.84, 95 % CI=0.78–0.90) (P for difference = 0.002). For hospitalizations, overall associations were in the expected direction, but trends were not significant due to fewer hospitalizations.

CONCLUSIONS: In a large, nationwide sample of Medicare beneficiaries, influenza vaccination among 18–64 year-olds was inversely associated with influenza-like illness in the elderly.

ASSOCIATION OF LONG-TERM OPIOID AND/OR BENZODIAZEPINE RECEIPT AND MEDICATION COUNT WITH MORTALITY AMONG HIV-INFECTED AND UNINFECTED PATIENTS Daniel Weisberg¹; Kirsha S. Gordon²; William Becker^{3,2}; E. Jennifer Edelman³; J. R. Gaither¹; Robert D. Kerms^{1,2}; Janet P. Tate²; Amy C. Justice^{1,3}; David A. Fiellin³. ¹Yale University, New Haven, CT; ²VA Connecticut Healthcare System, West Haven, CT; ³Yale University, New Haven, CT. (Tracking ID #1936560)

BACKGROUND: In the United States, prescribing of controlled substances, including opioid analgesics and benzodiazepines (BZDs), is on the rise. Opioids and BZDs are known to have synergistic effects on sedation and respiratory depression leading to overdose. Those receiving long-term (LT) opioids and BZDs, older patients and those treated for HIV infection deserve particular attention due to greater exposure, the prevalence of polypharmacy and a diminished capacity for drug metabolism and elimination. We previously demonstrated an association between polypharmacy and mortality among HIV infected and uninfected (HIV+/-) patients. The prevalence and harms of LT opioid and/or BZD receipt beyond polypharmacy in HIV+/- patients are unknown.

METHODS: We used data from the Veterans Aging Cohort Study-Virtual Cohort to analyze the association between opioid/BZD receipt and all-cause mortality. Patients with cancer diagnoses, and HIV+ patients not on anti-retroviral therapy (ART) were excluded. LT medication receipt was defined (using pharmacy fill/refill data) as greater than 90 consecutive days of therapy allowing a 30-day gap. Medication count was determined by average LT concurrent medications over the study period, excluding ART, opioids and BZDs. All-cause mortality was based on the Veterans Health Administration Vital Status File. To account for confounding by indication, propensity scores for opioid/BZD receipt were generated using a logistic regression model including demographics, smoking, pain diagnoses, HIV and HCV status and other medical and psychiatric conditions. Individuals were 1:1 matched by propensity score, using a greedy algorithm. Cox regression was used to generate hazard ratios for all-cause mortality. In sensitivity analysis, separate models were run by HIV status.

RESULTS: From 64,441 eligible individuals, with 14550 opioid and/or BZD recipients, 12,881 pairs were included in the matched sample. The propensity score model had good discrimination ($c=.76$) and produced a well-balanced sample (Table 1). There were 758 deaths. Both opioid and BZD receipt were associated with a $>30\%$ increase in mortality; patients receiving both had a $>50\%$ increase in mortality. Each additional medication was associated with 4 % higher mortality risk. Results from HIV+/- strata were similar to overall findings (Table 2).

CONCLUSIONS: LT opioid and BZD receipt and average medication count each showed a significant independent risk for mortality, after adjustment for confounding by indication using propensity score matching. The incremental harm associated with opioid and/or benzodiazepine receipt was greater than would be expected due to their contribution to polypharmacy alone. These observational findings suggest the need for designing and testing interventions prioritizing the safe use of opioids and BZDs.

Table 1: Propensity score matching

	Opioid and/or BZD receipt, yes	Opioid and/or BZD receipt, no	P value
Male	12551 (97.4)	12551 (97.4)	1
Age, mean (std dev)	47.6 (8.2)	48.0 (9.0)	.0002
White race, n (%)	6417 (49.8)	6356 (49.3)	.767
HIV+, n (%)	2908 (22.6)	2866 (22.3)	.530
Medication count, mean (std dev)	5.90 (3.8)	5.82 (4.0)	.093

Table 2: Mortality, Hazard Ratio (95 % Confidence Intervals)

	Overall	HIV –	HIV +
Opioid receipt	1.38 (1.20–1.59)	1.25 (1.05–1.50)	1.46 (1.15–1.87)
BZD receipt	1.33 (1.12–1.58)	1.34 (1.08–1.66)	1.28 (.95–1.71)
Opioid and BZD receipt	1.56 (1.24–1.96)	1.34 (1.00–1.81)	1.85 (1.29–2.68)
Medication count	1.04 (1.02–1.06)	1.05 (1.03–1.07)	1.03 (1.00–1.07)

ASSOCIATION OF OPIOID USE WITH FALLS AND FRACTURES AMONG OLDER MEN WITH MUSCULOSKELETAL PAIN Erin E. Krebs^{1,2}; Misti Paudel²; Brent C. Taylor^{1,2}; Douglas Bauer⁴; Howard A. Fink^{1,2}; Nancy E. Lane³; Kristine E. Ensrud^{1,2}. ¹Minneapolis VA Health Care System, Minneapolis, MN; ²University of Minnesota, Minneapolis, MN; ³University of California at Davis, Sacramento, CA; ⁴University of California at San Francisco, San Francisco, CA. (Tracking ID #1936417)

BACKGROUND: Older adults are disproportionately affected by painful musculoskeletal conditions and receive more opioid analgesics than younger adults, but insufficient data are available about potential benefits and harms of opioid therapy in older adults. The objectives of this study were to evaluate potential adverse effects of opioid analgesics on prospectively assessed falls and fractures among older men with persistent musculoskeletal pain.

METHODS: This is a secondary analysis of data from the Osteoporotic Fractures in Men (MrOS) study, a longitudinal cohort study of 5994 community-dwelling men age ≥ 65 years. This analysis includes MrOS participants who reported having back, hip, or knee pain most or all of the time at baseline. Medication exposure and covariate data were collected from participants at baseline and two follow-up visits. Participants were contacted every 4 months to assess fall and fracture outcomes; follow-up contacts were $>99\%$ complete. For falls, the outcome was one or more falls reported during each 4-month period. Fracture outcomes were incident events confirmed with radiographic reports and evaluated in 3 categories: any clinical fracture; major osteoporotic fracture (fractures of the hip, wrist, spine and shoulder); and hip fracture. Propensity scores (PS), representing the conditional probability of receiving opioids, were estimated for each visit using a logistic regression model that included age, BMI, smoking, medical comorbidities, frailty status, activity level, cognitive performance, pain location, and other covariates. To achieve adequate balance of covariates between opioid users and non-users within PS quintiles, men with PS < 0.03 (meaning $<3\%$ conditional probability of receiving opioids) were excluded from the primary analyses. Generalized estimating equations (GEE) were used to model the relationship between repeated measures of opioid use and falls, controlling for time-varying PS quintile. Cox proportional survival analyses were used to model associations between opioid use and incident fractures.

RESULTS: The analytic cohort included 2,732 men with back, hip, or knee pain at baseline. A total of 351 men (12.8 %) reported opioid use at one or more study visits. Over 9.1 (SD 4.0) years of follow-up, 2069 participants reported at least one fall, 318 had any clinical fracture, 149 had a major osteoporotic fracture, and 60 had a hip fracture. In the primary model, the relative risk of falling was 1.10 (95 % CI: 0.97, 1.24) for opioid users compared with non-users. Point estimates for all fracture outcomes were higher for opioid users than non-users, but none of the associations were statistically significant (Table).

CONCLUSIONS: We found non-significantly higher fall and fracture rates for opioid users compared with non-users. This analysis of MrOS data has major advantages over prior studies, including detailed assessment of potential confounders and rigorous prospective ascertainment of fall and fracture outcomes. Study

limitations include lack of detailed opioid dose data and infrequent medication assessment. Power was limited for major osteoporotic fracture and hip fracture events, so we cannot exclude a moderate effect of opioid use on these outcomes.

Hazard ratio (HR) of fracture outcomes for opioid users vs. non-users

Outcome	HR (95 % CI)
Any clinical fracture	1.08 (0.87–1.34)
Major osteoporotic fracture	1.34 (0.88–2.03)
Hip fracture	1.55 (0.80–3.02)

ASSOCIATIONS BETWEEN INTERNAL MEDICINE RESIDENT SCHOLARSHIP AND CLINICAL PERFORMANCE Luke A. Seaburg; Amy T. Wang; Colin P. West; Darcy Reed; Andrew J. Halvorsen; Gregory Engstler; Amy Oxentenko; Thomas J. Beckman. Mayo Clinic, Rochester, MN. (Tracking ID #1936416)

BACKGROUND: The Accreditation Council for Graduate Medical Education requires that resident physicians participate in scholarly activities. Studies have shown that dedicated research time during residency is associated with increased publication, and residents who publish are more likely to select careers in academic medicine and achieve higher academic rank. However, it is unknown whether research productivity among residents is related to broad measures of clinical achievement during residency training. Therefore, we examined associations between the quantity of Mayo Clinic internal medicine residents' peer-reviewed publications and measures of their knowledge (ABIM certification examination scores), skills (mini-clinical examination scores) and multi-source evaluations of performance.

METHODS: This was a longitudinal study of 312 post-graduate-year three (PGY-3) residents at the Mayo Clinic in Rochester, Minnesota from 2006 to 2012. To quantify scholarship, we identified peer-reviewed articles published in Ovid MEDLINE between July of each resident's match year and the end of their graduation year. Outcomes included ABIM certification examination scores, mini clinical examination (mini-CEX) scores, and validated multi-source assessments of performance by resident-peers, faculty, and non-physicians. Scores for the clinical performance assessment items were averaged to form an overall score ranging from 1 to 5. Covariates included sex (male/female), medical school (U.S. versus international medical graduate), track (categorical versus clinician-investigator), PhD (yes/no), age at PGY-3 start, and percent correct on PGY-3 ITE examination. Associations between quantity of resident publications and first author status—and ABIM, mini-CEX and clinical performance assessment scores—were determined using multivariate linear regression analysis. The threshold for statistical significance was set at $p<0.01$ to account for multiple comparisons.

RESULTS: Of the 312 PGY-3 residents, 199 (63.8 %) were male, 263 (84.3 %) were U.S. medical graduates, 282 (90.4 %) were categorical, and 11 (3.5 %) had PhD degrees. Their average age at PGY-3 start was 29.7 years. The residents published 667 papers, of which 462 were research papers, 204 were case reports, and 288 were first-authored. On adjusted analysis, multi-source evaluations of clinical performance were significantly associated (beta; p-value) with the numbers of research articles (0.013; 0.003), overall publications (0.013; 0.0009), and first-authored articles (0.017; 0.007). There were no statistically significant associations between quantity of publications and ABIM certification examination or mini-CEX scores.

CONCLUSIONS: This may be the first study to demonstrate that, among resident physicians in training, scholarly achievement is associated with clinical performance as determined by observation-based assessments from resident peers, faculty, and non-physicians. Furthermore, performance assessment scores were linked to the publication of journal articles that were first-authored and research-focused. These findings suggest that scholarly productivity may be an indicator of clinical performance during residency training, and underscore the importance of research programs in graduate medical education.

ASSOCIATIONS BETWEEN MEDICAL HOME CHARACTERISTICS AND SUPPORT FOR PATIENT ACTIVATION IN THE SAFETY NET: UNDERSTANDING DIFFERENCES BY RACE, ETHNICITY, AND HEALTH STATUS Robert S. Nocón¹; Yue Gao¹; Kathryn E. Gunter¹; Janel Jin²; Lawrence P. Casalino³; Michael T. Quinn¹; Sarah Derrett⁴; Wm Thomas Summerfelt⁵; Elbert S. Huang¹; Sang Mee Lee⁶; Marshall Chin¹. ¹University of Chicago, Chicago, IL; ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ³Weill Cornell Medical College, New York, NY; ⁴Massey University, Palmerston North, New Zealand; ⁵Advocate Healthcare, Chicago, IL; ⁶University of Chicago, Chicago, IL. (Tracking ID #1936110)

BACKGROUND: Few studies have evaluated whether the patient-centered medical home (PCMH) supports patient activation, and existing evidence is mixed. No studies have evaluated whether support for patient activation differs among racial and ethnic groups in a PCMH. This is critical because activation is lower on average among minority patients. We sought to assess the association between clinic PCMH characteristics and patient perception of clinic support for patient activation, and whether that association varies by patients' self-reported race, ethnicity, and health status.

METHODS: We conducted a cross-sectional analysis of PCMH characteristics and patient-assessed clinic support of patient activation in 24 safety net clinics across five states. PCMH characteristics were measured via surveys of 271 providers and staff. The provider and staff survey produced a 0 (worst) to 100 (best) PCMH score based on a scale created by the authors and described previously in the literature. Clinic scores were created by averaging provider/staff responses. Clinic support of patient activation was measured via surveys of 1,656 patients. The patient survey used the patient activation scale of the Patient Assessment of Care for Chronic Conditions to produce a 0 (worst) to 100 (best) score for clinic support for patient activation. Patient race, ethnicity, and health status were based on self-report in the patient survey. To investigate the relationship between PCMH characteristics and patient activation, while allowing for a clustering effect of patients within clinics, we fitted multivariate models using generalized estimating equation models with an exchangeable correlation structure. We analyzed interactions terms to assess how the association of PCMH characteristics and patient activation varied by race/ethnicity and health status subgroups. We interpret the association in terms of a 10-point change in PCMH score, a difference we found to be operationally meaningful in previous work.

RESULTS: We received 214 (79.0 %) provider and staff survey responses and 735 (44.4 %) patient survey responses. Mean PCMH score among the 24 clinics was 58.7 ($SD=6.4$). The mean score for patient perception of clinic support of patient activation was 68.8 ($SD=30.0$). Across all patients, a 10-point higher PCMH score was associated with a 5.6-point higher score for patient perception of clinic support for patient activation (95 % CI, 1.3–9.9). The association between PCMH score and patients' perception of clinic support for patient activation was particularly strong among minority patients in fair or poor health: a 10-point higher PCMH score was associated with a 16.2-point (CI 1.7–30.6) higher score for clinic support of patient activation among Hispanic patients in fair or poor health and a 34.1-point higher score among black patients in fair or poor health (CI 9.1–59.1). The effect of PCMH score on patient activation score among black patients with poor/fair health status was statistically significantly different from the effect seen among non-Hispanic white patients in good or better health.

CONCLUSIONS: In a population of safety net patients, PCMH characteristics showed a moderate, positive association with patients' perception of clinic support for activation; the magnitude of association was notably larger for minority patients in poor/fair health status. The PCMH may be promising for reducing disparities in patient activation for ill racial and ethnic minority patients.

ATTITUDES TOWARD INTERNAL MEDICINE RESIDENT PROFESSIONALISM TRAINING Laura Nichols; Kathryn E. Fletcher; Brent Nichols. Medical College of Wisconsin, Wauwatosa, WI. (Tracking ID #1934886)

BACKGROUND: Professional conduct is a core competency of medical practice and residency training. Defining, teaching and evaluating professionalism is challenging and requires collaboration between residents and faculty. In order to facilitate this effort, it is important to understand the beliefs and attitudes of those involved in the process. It was our objective to understand current modalities used, attitudes toward currently utilized curriculum and potential areas for improvement in professionalism training.

METHODS: Two surveys (one for residents and another for program directors) were developed using previously identified methods of teaching and evaluating professionalism. We distributed the survey link via email. Data was analyzed for associations using a chi-squared test.

RESULTS: Sixty-seven program directors and 589 residents completed the respective surveys. The majority (94 %) of residents felt that professionalism education was relevant to their development as physicians. Forty-two percent of programs reported having a formal professionalism curriculum, though the majority of program directors (86.6 %) and residents (87.1 %) felt that residents could be taught professionalism. Residents who reported having a formal professionalism curriculum were significantly more likely to rate the quality of their professionalism training as adequate (27 %) or very good (28 %) ($P<0.0001$). Commonly utilized evaluation modalities included faculty evaluation forms (97.0 %) and completion of administrative tasks (85.1 %). Role modeling was the most utilized teaching modality (80.3 %). Residents

noted faculty evaluation (66.0 %) and ancillary staff evaluation (61.9 %) to be most effective evaluation methods, while Objective Structured Clinical Examinations (OSCE) and traditional examinations ranked lowest. Role modeling (66 %) and faculty mentorship (48.7 %) were felt by residents to be the most useful methods of teaching professionalism.

CONCLUSIONS: We examined attitudes of residents and program directors toward professionalism curricula to aide in the formation of effective professionalism education. Consistent with previous literature, formal didactics and examinations were noted to be less effective than staff evaluations and role modeling. Less than half of programs reported having professionalism curricula; however, residents who had a formal curriculum were more likely to report high quality professionalism teaching. A multifaceted approach with a focus on faculty and ancillary staff evaluation, role modeling and mentorship is likely to be the most well-received curriculum.

AUTOMATED ELECTRONIC SEPSIS ALERTS: A SYSTEMATIC REVIEW

Anil N. Makam¹; Oanh K. Nguyen¹; Andrew Auerbach². ¹University of Texas Southwestern, Dallas, TX; ²University of California San Francisco, San Francisco, CA. (*Tracking ID #1938467*)

BACKGROUND: Timely treatment of sepsis, including adequate fluid resuscitation and appropriate antibiotic administration, decreases morbidity and mortality. However, there are diagnostic and therapeutic delays in deploying early-goal directed therapies due to the resource intensive nature of these protocols. To circumvent these delays, automated, electronic sepsis alerts are being implemented to facilitate the delivery of timely and effective care. We sought to systematically evaluate whether automated, real-time electronic sepsis alerts can accurately identify sepsis, and improve process measures and outcomes for patients with sepsis.

METHODS: We systematically searched MEDLINE, Embase, The Cochrane Library, and CINHAL from database inception till August 13, 2013. Two independent reviewers selected studies that empirically evaluated one or both of our prespecified objectives. We excluded studies of bacteremia, nosocomial infections, or rapid response interventions. Two independent reviewers extracted data and assessed the risk of bias. Accuracy of sepsis detection was measured by sensitivity, specificity, positive and negative predictive values and likelihood ratios. Efficacy was assessed by changes in various process measures (i.e. time to antibiotics) and outcomes (length of stay, mortality). Heterogeneity in setting, design, and definitions of the alert precluded a meta-analysis.

RESULTS: We searched 1,091 citations and identified six studies for inclusion, four for the identification of sepsis ($n=34,328$) and four for the evaluation of automated, real-time sepsis alerts ($n=6,723$). The definition of sepsis alert thresholds varied, but included abnormal systemic inflammatory response syndrome (SIRS) criteria or abnormal SIRS criteria plus organ dysfunction. The accuracy of alerts to identify sepsis varied greatly depending on the clinical setting and the definition of sepsis used for the alert system, with sensitivity ranging from 36.2 to 98.9 %, specificity, 30.7–99.6 %, positive likelihood ratio, 1.4–145.8, and negative likelihood ratio, 0.04–0.86. There was modest evidence for improvement in process measures, such as lactate collection and antibiotic administration, among patients in non-ICU settings; however, without corresponding improvements in mortality or length of stay. We found no studies that reported on overuse and potential harms due to false positive alerts.

CONCLUSIONS: Automated sepsis alerts derived from electronic health records may improve care processes but tend to have poor positive predictive value and do not improve mortality or length of stay. Future efforts should develop and study methods for sepsis alert systems which avoid the potential for alert fatigue while improving outcomes.

AUTOPSY IN THE AGE OF ADVANCED DIAGNOSTIC TECHNOLOGY

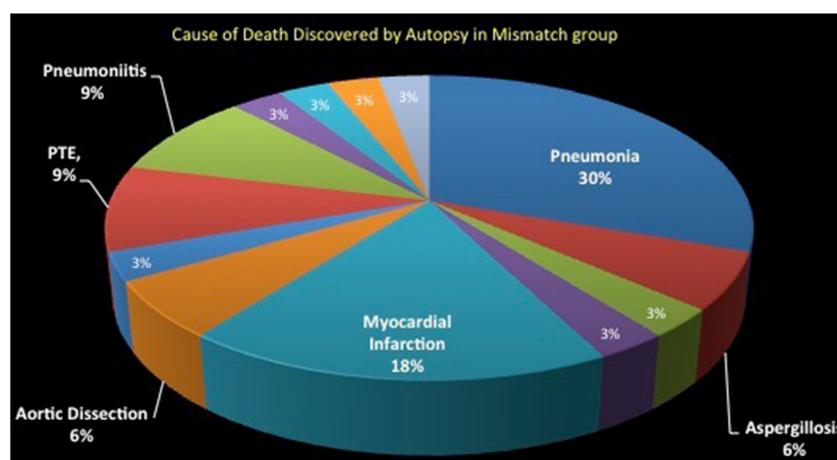

David Chia²; Ali Ershadi¹; Majid Sadigh¹; Steven I. Aronin². ¹Western Connecticut Health Network, Danbury, CT; ²Yale, Waterbury, CT. (*Tracking ID #1928285*)

BACKGROUND: Traditionally, the role of autopsy has had many benefits to the healthcare system, including illumination of the exact cause of death, determination of the rate of clinical errors, assurance of the quality of care, and identification of new diseases or changes in preexisting ones. However, autopsy rates have declined worldwide. In the United States, the in-hospital autopsy rate has fallen to 5–10 % from its peak of 70 % in the early 1960s. Furthermore, a heavy reliance on advanced diagnostic technologies have given an impression of diagnostic adequacy that invalidates the present need for autopsy. However, despite these advances in technology, the reported discrepancy between clinical and autopsy diagnoses remains unchanged at 10–30 %.

METHODS: We conducted a retrospective review of all autopsies performed on patients who died in two community hospitals between January 2008 and December 2012. Major discrepancies between clinical and autopsy diagnoses were classified into two categories: significant errors that had the proper diagnosis been made would have changed management and possibly outcome (type I) and significant errors that had the proper diagnosis been made would not have changed management or outcome (type II).

RESULTS: 2,409 deaths occurred during the study period and autopsies were conducted on 284 patients (11 %). Autopsies performed on fetuses, patients who were dead on arrival to the hospital, and those with inadequate documentation were excluded from our study. Major discrepancies were noted in 20 % (33/164) of cases of which 79 % (26/33) were type I errors. The most commonly misdiagnosed conditions included pneumonia (30 %), myocardial infarction (18 %), pulmonary embolism (9 %) and pneumonitis (9 %). Nearly half of patients (17/33) with major discrepancies died under unclear clinical circumstances. Autopsy established the cause of death in 88 % (15/17) of these cases. Major discrepancies occurred mainly because either the diagnosis was not considered on the differential diagnosis (55 %) or the diagnosis was considered, but the result of appropriate diagnostic evaluation was misleading (30 %).

CONCLUSIONS: Despite advances in medical technology, major discrepancies between clinical and autopsy diagnoses continue to occur at relatively high rates. The majority of these discrepancies would have changed management decisions and may have altered outcomes if the proper diagnosis had been made. These discrepancies often occurred because the proper diagnosis was either not considered in the differential diagnosis or the result of appropriate diagnostic testing was misleading. As a result, autopsy should continue to have an important role in the healthcare system, while physicians should maintain broad differential diagnoses and be critical of unexpected results on diagnostic evaluation.

AWARENESS OF CENTRAL VENOUS CATHETERS: A PATIENT SAFETY SURVEY Rachel E. Thompson¹; Natalie Melin¹; Vineet Chopra². ¹University of Washington, Seattle, WA; ²University of Michigan, Ann Arbor, MI. (*Tracking ID #1938689*)

BACKGROUND: Central lines are commonly used in the care of hospitalized patients. Each day a central line is in place the risk of complications such as bloodstream infection rises. Yet central lines often remain in place after they are no longer clinically useful. Preliminary data suggests one obstacle to the timely removal of central lines may be physician being unaware—as was demonstrated in the case of urinary catheters. The goal of this study is to determine the extent of physician awareness of their patients' central lines.

METHODS: We interviewed intern, resident, and attending physicians on inpatient medical services at an academic hospital. Patients hospitalized on the medicine non-ICU, medicine ICU, cardiology and hospitalist services were included. Physicians were read a list of patients for whom they had direct responsibility and asked whether each had (1) a central venous catheter (CVC) or (2) a peripherally inserted central catheter (PICC). “Yes” or “no” responses were recorded for both types of central line. Physician responses were cross-checked with the hospital’s validated daily central line report for accuracy.

RESULTS: 375 patient records were accessed and their providers interviewed regarding awareness of presence of a CVC or PICC. There were 218 interviews with interns, 264 with senior residents and 347 with attendings. Fifty-two cases had a CVC and 23 a PICC. Of those with either a CVC or PICC, overall provider recall accuracy ranged from 82 to 93 %. On teaching teams, attendings were significantly more likely to miss a central line than residents or interns ($p<0.01$). There was no significant difference in missed lines between teaching attendings and hospitalists. Of the ICU attending interviews, lines were present in 36 % compared to only 13 % among non-ICU. Attending with work that included ICU care were less likely to miss a line (13.9 v 36.1 %, $p <0.05$). These attendings were also more likely to falsely recall a line when no line was present than the non-ICU attendings (15.4 v 5.3 %, $p<0.01$).

CONCLUSIONS: Our results demonstrate that many physicians are not aware of whether their patient has a central line. Errors in recall occurred in both directions, potentially suggesting a deep-rooted unawareness. The frequency of lines among patients may influence the direction of recall error. The overall greater awareness observed among interns could relate to smaller case-loads. Each day a physician fails to remove an unnecessary line unjustly exposes the patient to an increasing risk of complications. It is important to target awareness of central lines to improve patient safety.

AWARENESS OF PREDIABETES AND ENGAGEMENT IN DIABETES RISK-REDUCING BEHAVIORS Anjali Gopalan^{1,3}; Ilona Lorincz⁴; Christopher Wirtalla⁶; Judith A. Long^{2,3}; Steven C. Marcus^{2,5}. ¹Philadelphia VA Medical Center, Philadelphia, PA; ²Philadelphia VA Medical Center, Philadelphia, PA; ³Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; ⁴Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; ⁵University of Pennsylvania, Philadelphia, PA; ⁶Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA. (*Tracking ID #1933194*)

BACKGROUND: Numerous high quality studies have demonstrated the benefit of lifestyle modification, including weight loss, exercise, and a healthy diet, in the prevention of diabetes among those with prediabetes. Almost a third of the U.S. adult population meets criteria for prediabetes and without any intervention, 25 % will develop diabetes within 3 to 5 years. Despite the proven benefits of lifestyle changes and increasing numbers of community-based diabetes prevention programs, only about half of those with prediabetes report engaging in behaviors aimed at preventing the onset of diabetes. One barrier is low patient awareness of being at risk. In this study we aimed to determine whether there is a difference in the performance of diabetes risk-reduction behaviors between individuals who are aware of their prediabetes diagnosis compared to those who are unaware.

METHODS: We conducted a pooled cross-sectional analysis from two consecutive cohorts (2007–2008 and 2009–2010) of the National Health and Nutrition Examination Survey (NHANES). Subjects under age 20, pregnant woman, and those with missing responses to questions relating to diabetes history, physical activity, diet, and weight history were excluded, as were individuals missing all three lab values used to diagnose prediabetes: the hemoglobin A1C (HbA1C), a fasting plasma glucose (FPG), and the two-hour oral glucose tolerance test (OGTT). Patients with a self-reported history of diabetes were classified as diabetes-aware. The remaining analytic sample was identified using the nationally accepted laboratory criteria to define prediabetes: $5.7\% \leq A1C < 6.5\%$, $100 \text{ mg/dL} \leq \text{FPG} < 126 \text{ mg/dL}$, and/or $140 \text{ mg}/$

$\text{dL} \leq \text{OGTT} < 200 \text{ mg/dL}$. Patients were classified as prediabetic if they met one of these criteria and did not meet any criteria for diabetes. The prediabetic population was then categorized into prediabetes aware and unaware based on participants’ self-report. We then used multivariate logistic and linear regression to estimate the effect of awareness of prediabetes on the likelihood of the following outcomes: engagement in physical activity, weight-related behaviors, and number of fast food/pizza meals eaten weekly. Any weight related behavior was defined by reported intention to lose weight or maintain weight, while appropriate-weight behavior was defined as an intention to lose weight for those with a $\text{BMI} \geq 25$ and a desire to maintain weight for those with a $\text{BMI} < 25$.

RESULTS: 34.4 % (3,635/10,556) met criteria for prediabetes. 8.5 % (310) of those meeting these criteria self-reported a diagnosis of prediabetes. Those who were aware of prediabetes differed significantly from those who were unaware by age (55.6 vs 51.7, $p<0.001$), but did not differ based on gender, educational attainment, income, or ethnicity. Subjects aware of prediabetes were also more likely to report a regular source of care (94.2 % vs. 85.7 %, $p<0.001$), have a family history of diabetes (45.3 % vs. 35.9 %, $p=0.02$), have a history of hypertension or hyperlipidemia (58.1 % vs 35.1 %, $p<0.001$ and 53.8 % vs. 29.5 %, $p<0.001$, respectively), and to report that a physician told them they were overweight or obese (57.2 % vs. 33.3 %, $p <0.001$). After adjusting for age, gender, ethnicity, education, number of healthcare visits in the past year, family history of diabetes, being told they were overweight/obese, self-reported limitation on work/activity, BMI, and medications for hypertension and hyperlipidemia, adults who self-reported having prediabetes were significantly more likely to report engagement in any physical activity (any level of intensity) on a weekly basis, adjusted odds ratio (AOR) 1.3, ([95 % CI 1.0–1.7]; $p=0.046$) and engagement in moderate or vigorous physical activity, AOR 1.3, ([95 % CI 1.1–1.5]; $p=0.01$). Adults with awareness of prediabetes were also significantly more likely to report engaging in any weight-related behavior AOR 1.8, ([95 % CI 1.3–2.5]; $p=0.001$) and in appropriate-weight related behavior AOR 1.4, ([95 % CI 1.0–2.0]; $p=0.05$). There was no difference noted in number of fast-food/pizza meals eaten weekly based on awareness of prediabetes (1.9 meals vs. 1.6 meals, $p=0.5$).

CONCLUSIONS: Adults who were aware of meeting diagnostic criteria for prediabetes were significantly more likely to engage in moderate or vigorous weekly exercise and were more likely to report engagement in appropriate weight-related behaviors. While the cross-sectional nature of the data limits conclusions regarding continued adherence to these risk-reduction efforts, engagement is unarguably the first step toward lifestyle changes. Increasing our patients’ awareness of prediabetes could result in increases in exercise and weight management and, most importantly, to decreases in the incidence of diabetes and improved health outcomes.

AZITHROMYCIN IS ASSOCIATED WITH INCREASED CARDIAC EVENTS BUT LOWER MORTALITY FOR OLDER PATIENTS HOSPITALIZED WITH PNEUMONIA Eric Mortensen^{1,2}; Ethan Halm²; Michael J. Fine³; Christopher Johnson^{1,2}; Antonio Anzueto⁴. ¹VANTHCS, Dallas, TX; ²University of Texas Southwestern Medical Center, Dallas, TX; ³VA Pittsburgh Health Care System, Pittsburgh, PA; ⁴South Texas Veterans Health Care System, San Antonio, TX. (*Tracking ID #1931222*)

BACKGROUND: Although clinical practice guidelines recommend combination therapy with macrolides, including azithromycin, as first line therapy for patients hospitalized with pneumonia, recent research suggests that azithromycin may be associated with increased cardiovascular events. The purpose of this study was to examine the association of azithromycin use with all-cause mortality and cardiovascular events for patients hospitalized with pneumonia.

METHODS: We conducted a retrospective national study using Department of Veterans Affairs administrative data of patients hospitalized at any Veterans Administration acute care hospital. We included patients >65 years hospitalized with pneumonia in fiscal years 2002–2012. We included only those who received antibiotic therapy concordant with national clinical practice guidelines. Our outcomes included all-cause mortality, cardiac arrhythmias, heart failure, myocardial infarction, and any cardiac event. We used propensity score matching to control for the possible effects of known confounders with conditional logistic regression.

RESULTS: Out of the 77,972 patients identified, our propensity-matched groups were composed of 34,763 azithromycin-exposed and 34,763 matched unexposed. There were no significant differences in potential confounders between groups after matching. We found that 90-day mortality was significantly lower in those who received azithromycin (exposed- 17.4 % vs. unexposed- 22.8 %, odds ratio [OR] 0.71, 95 % confidence interval [CI] 0.68–0.73). However, we found significant increased odds of any cardiac event (43.2 % vs 42.2 %, OR

1.04, 95 % CI 1.01–1.07), myocardial infarctions (4.9 % vs. 4.2 %, OR 1.17, 95 % CI 1.09–1.26), and cardiac arrhythmias (26.5 % vs. 25.6 %, OR 1.04, 95 % CI 1.002–1.07) but not heart failure (26.1 % vs. 25.8 %, OR 1.02, 95 % CI 0.98–1.05).

CONCLUSIONS: In patients hospitalized with pneumonia we found that although azithromycin is associated with a small increase in cardiac events it is also associated with a significant decrease in all-cause mortality. Our study supports the current clinical practice guidelines that recommend the use of azithromycin as part of empiric combination therapy.

BACTERIAL CONTAMINATION OF RESIDENT iPADS: LAME DUCK OR TROJAN HORSE? *Tanu S. Pandey¹; Kamaljit Singh²; German E. Giese¹; Michael Alebich¹; Shubhra Gupta¹. ¹John H Stroger Hospital of Cook County, Chicago, IL; ²Rush University Medical Center, Chicago, IL. (Tracking ID #1939546)*

BACKGROUND: The advent of the Apple iPad, has brought about a revolution in the delivery of medical care. Though clothing, stethoscope and phone contamination has been well documented, to date, no study has examined the bacterial contamination of iPads. Our study aims to establish the rates of bacterial contamination of iPads used by residents in two urban teaching hospitals. We present the findings from one of these institutions.

METHODS: The study was funded by a collaborative research grant from the parent institutions. Twenty four residents from John H. Stroger Jr, Hospital of Cook County who used an iPad for patient care were enrolled into the study. They provided their iPad to the investigators during work hours for culture at random times. A pre-moistened swab was obtained from two 5 cm² areas of the screen, as well as the “home” button. These swabs were delivered to the microbiology lab promptly and inoculated onto three agar plates for aerobic and anaerobic culture, isolate identification and antibiotic sensitivity. An anonymous questionnaire with demographic information was provided to the residents at time of swab.

RESULTS: All 24 devices were either iPads or iPad mini. There were five PGY-1, eight PGY-2, and eleven PGY-3 residents. Ninety-two percent residents took their device regularly inside patients’ rooms and 67 % placed them on the bed, table or elsewhere. Sixty-three percent carried their device in their hands as opposed to a case or coat pocket. Ninety-six percent used the same device for work and personal reasons and 50 % did not clean them at all. All devices grew multiple skin flora including coagulase negative staphylococcus. One device grew MRSA, three devices grew MSSA, one Acinetobacter and six grew alpha-hemolytic streptococcus. There was no significant statistical difference in contamination between those who cleaned their devices versus those who did not (OR 2.0, 95 % CI 0.3843 to 10.4096, *p* value=0.4102).

CONCLUSIONS: The iPad is changing how medicine is practiced; however, no study has examined potential harms afforded by these devices. Our study revealed that the iPad does harbor potentially dangerous pathogens and little regulations guide the decontamination of these devices at the bedside. The relatively low prevalence of organisms is reassuring but further studies in large numbers are needed to establish the role of the iPad in increasing hospital-acquired infections. Based on the behavior of residents in this study, standard precautions for the use of these devices around patients is recommended.

BAR AND NIGHTCLUB INTERVENTION TO DECREASE YOUNG ADULT SMOKING IN NEW MEXICO *Sara Kalkhoran¹; Pamela M. Ling^{1,2}; Jeffrey W. Jordan³. ¹University of California, San Francisco, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA; ³Rescue Social Change Group, San Diego, CA. (Tracking ID #1937993)*

BACKGROUND: Over 20 % of young adults in New Mexico are current smokers, which exceeds current national estimates. We evaluated the effect of an anti-tobacco Social Branding intervention on daily and non-daily smoking rates among young adult bar patrons.

METHODS: A series of cross-sectional surveys were collected from adults aged 18–26 in bars and nightclubs popular among young adults in Albuquerque, New Mexico from 2009 to 2013 using randomized time-location sampling. A Social Branding intervention was implemented in Albuquerque during this time. Social Branding is a variant of social marketing using commercial marketing strategies to compete with tobacco marketing by creating a smoke-free brand to promote smoke-free lifestyles within a specific bar subculture. This intervention focused

on the “Partier” culture, which was characterized by attendance at large nightclubs, fashion consciousness, valuing physical attractiveness, and achieving high social status by exuding an image of confidence and financial success. Multivariate multinomial regression was used to evaluate differences in rates of daily (smoked on 25–30 of past 30 days) and non-daily (smoked 1–24 of past 30 days) cigarette use between baseline and each of 3 years of follow up, controlling for demographic characteristics, other risk behaviors, and tobacco-related attitudes.

RESULTS: Data was collected from 1066 individuals at baseline, and 767, 1242, and 1231 participants at follow-up years 1, 2, and 3, respectively. Current smoking rates decreased from 47.4 % at baseline to 37.4 % at follow-up year 3 (*p*<0.001). In multivariate multinomial regressions, those surveyed at year 3 had significantly lower odds of being either a current daily (OR=0.41, 95%CI [0.26–0.64]) or non-daily (0.57, [0.41–0.80]) smoker compared to baseline. Factors associated with increased odds of both daily and non-daily smoking included lower education, LGBT sexual orientation, advertising receptivity, binge drinking, and higher trend sensitivity (a measure of social personality traits and frequency/intensity of socializing in bars) (Table 1). Other factors associated with daily and non-daily smoking are shown in Table 1.

CONCLUSIONS: Social Branding interventions aimed at young adult bar patrons may help reduce smoking rates in this population. Bar-based interventions tailored to specific subculture values and lifestyles are an efficient way to address risky behaviors in this hard-to-reach population that continues to have high rates of cigarette smoking.

Predictors of Being a Non-daily or Daily Smoker Among Young Adult Bar Patrons in Albuquerque, New Mexico

BARRIERS AND FACILITATORS TO PREVENTIVE CANCER SCREENING AMONG HMONG- AND SPANISH-SPEAKING PATIENTS *Elizabeth A. Jacobs^{1,3}; Rebecca J. Schwei¹; Maichou Lor². ¹School of Medicine and Public Health, University of Wisconsin, Madison, WI; ²School of Nursing, University of Wisconsin, Madison, WI; ³School of Medicine and Public Health, University of Wisconsin, Madison, WI. (Tracking ID #1938836)*

BACKGROUND: Language barriers in health care are a large and growing problem in the U.S. Having limited English proficiency (LEP) is a well-recognized risk factor for disparities in health care quality and outcomes. Despite access to high quality interpreter services, LEP patients still experience disparities in preventive cancer screening. We conducted a

qualitative study to better understand what factors might contribute to the disparities of cancer screening rates and their reduction among LEP patients seen in primary care.

METHODS: We conducted 28 semi-structured interviews with LEP patients who were eligible for preventive cancer screenings ($n=11$ Hmong, $n=10$ Spanish) and providers ($n=7$ Physician) in a large academic medical system. Patient interviews were conducted in Hmong or Spanish. We interviewed general internal and family practice physicians with varying percentages of LEP patients in their practice. All interviews were audio taped, transcribed verbatim, translated and coded for interpretation. Hmong, Spanish, and provider interviews were coded separately. Themes were developed using content analysis.

RESULTS: Physician recommendation, doctors who care about and respect their patients, gender-concordant doctors, and familial experience with cancer facilitated cancer screening in both Hmong- and Spanish-speaking participants. Physicians identified high quality interpreters, electronic medical record reminders, and educational materials in appropriate language as facilitators to delivering preventive cancer screening to their LEP patients. Two common barrier themes for Hmong- and Spanish-speaking patients were: (1) previous negative health care experiences, which created distrust of health care, and (2) lack of knowledge about cancer, what cancer prevention can do, and how to access community resources. Additional barriers for Hmong patients included poor quality interpreters and the need for health care decisions to be made by the nuclear family. Spanish-speaking patients uniquely identified lack of money or insurance, not enough time, and machismo in men as additional barriers to receipt of preventive cancer screening. Physicians reported that competing social, economic, and health demands of patients, visit time constraints, cultural beliefs of patients, and the nature of the screening tests (e.g. embarrassing) as barriers for LEP patients to seek screening.

CONCLUSIONS: We found that cancer screening is influenced by many different personal, family, interpreter, provider, health care system, and community factors. This study provides insights for addressing cancer health disparities for these two ethnic minority populations in our community. Culturally-tailored community cancer education about prevention and cancer in general, and preventive cancer screenings specifically, is a first step to increasing knowledge and acceptability of preventive cancer screening in Hmong- and Spanish-speaking patients. Additionally, helping providers navigate the barriers that they may face when suggesting preventive cancer services to LEP patients may also increase the rates of preventive cancer screenings in Hmong- and Spanish-speaking patients.

BEARING WITNESS: IMPACT OF A BRIEF INTERVENTION ON RESIDENT ADVERSE EVENT REPORTING Jennifer B. Cowart^{1,2}; Cynthia Peacock²; John Lin²; Addison A. Taylor^{1,2}. ¹Houston MEDVAMC, Houston, TX; ²Baylor College of Medicine, Houston, TX. (Tracking ID #1923141)

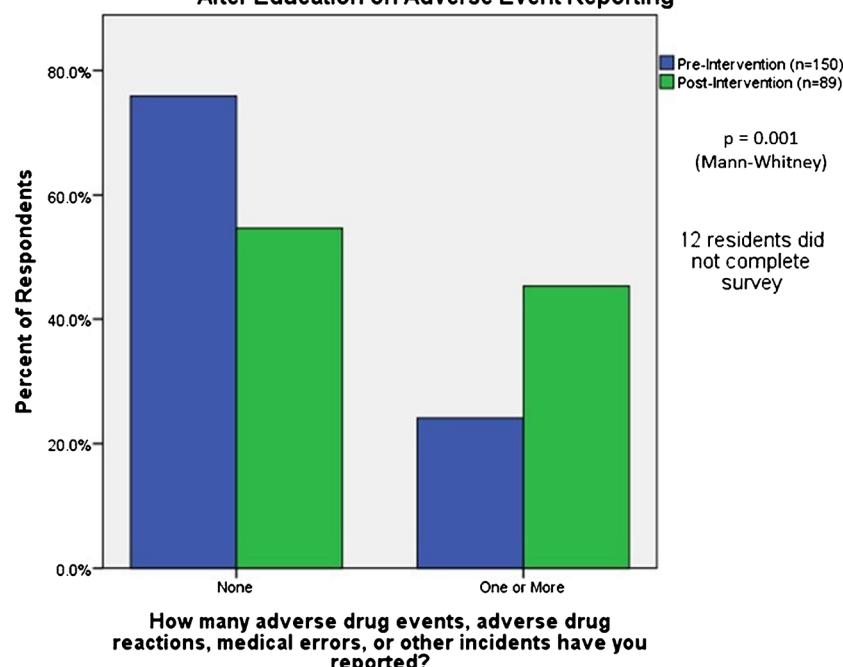

BACKGROUND: Recent ACGME guidelines require training in quality improvement and patient safety for resident physicians. Prior to the release of these guidelines, it was not clear how much training residents received in incident reporting. We sought to evaluate resident knowledge of hospital incident reporting systems, before and after a brief intervention aimed at increasing residents' submissions of incident reports.

METHODS: Internal medicine residents at a large academic program were asked to participate in an anonymous survey before and after a brief educational intervention. Invitations for the pre-test survey were sent by email in August 2012. Questions were given in the form of a statement with agreement rated on a 7-point Likert scale (from "strongly disagree" to "strongly agree"). Residents were also asked to enter the number of adverse event reports they had ever submitted. After survey completion, monthly lectures were given during regularly scheduled education time (15 min per month) at each hospital site. Reference guides for the incident reporting systems at each facility were added to the departmental website. Invitations for the post-test survey were sent in May 2013.

RESULTS: 189 residents were invited to participate in the 9-question survey on two occasions (378 total). 138 (73 %) completed all questions in 2012 and 84 (44 %) completed all questions in 2013. There were significant increases in residents' stated knowledge of mechanisms to report adverse events at two training institutions, with the median response changing from "disagree" to "agree" on a 7-point Likert scale ($p=0.000$ for both). Before specific instruction in incident reporting, only 24.1 % of residents stated they had ever reported an adverse event. At the post-survey, 45.3 % of the responding residents stated they had reported one or more adverse events ($p=0.001$). A majority of respondents agreed that they worked in a "culture of safety" (76.6 % before, 78.6 % after). There was no significant difference in the proportion of respondents who disagreed with this statement from before and after the intervention (10.2 % vs 9.5 %). The same held true of the proportion of residents who agreed that they were worried about being punished for reporting adverse events both before and after the intervention (27.5 % vs 28.6 %).

CONCLUSIONS: Brief education in adverse event reporting led to an increase in resident awareness of both reporting mechanisms and in self-reported submissions of adverse event reports. The increase in reporting did not correspond with an increase in residents perceiving themselves to be safe from reprisal. Areas for further investigation include identifying barriers to residents' reporting witnessed events and whether residents' concerns about reprisal for reporting of adverse events are a significant deterrent.

Number of Residents Who Reported One or More Adverse Events Before and After Education on Adverse Event Reporting

After education on adverse event reporting, residents were more likely to say they had reported at least one adverse event compared to before education on adverse event reporting.

BEDSIDE INTERPROFESSIONAL ROUNDS: MEDICINE PROVIDERS' PERCEPTIONS OF BENEFITS AND BARRIERS Jed Gonzalo¹; Ethan Kuperman²; Erik B. Lehman¹; Paul Haidet¹. ¹Penn State College of Medicine, Hershey, PA; ²University of Iowa, Carver College of Medicine, Iowa City, IA. (*Tracking ID #1937728*)

BACKGROUND: Interprofessional collaborative care models improve the quality of medical care. On inpatient medicine services, similar conceptualization amongst nurses and physicians regarding the process and goals of interprofessional rounds are required for successful implementation. However, little work has investigated front-line providers' perceptions regarding bedside interprofessional rounds. We evaluated the perceptions of nursing staff, resident, and attending physicians regarding the benefits and barriers to bedside interprofessional rounds.

METHODS: In June 2013, a cross-sectional survey was sent via email to all medicine nursing staff, resident and attending physicians in our hospital to assess their perceptions regarding the benefits and barriers to bedside interprofessional rounds, defined as "encounters that include the team of providers, at least two physicians plus a nurse or other care provider, discussing the case at the patient's bedside." The survey was developed from prior work on bedside rounds and a literature review; 16 items were related to "benefits" and 18 items were related to "barriers" to bedside interprofessional rounds. Descriptive statistics, non-parametric Kruskal-Wallis, and non-parametric correlation statistics were used.

RESULTS: Of 171 surveys sent, data were collected from 149 respondents (87 % response). Highest-ranked benefits to bedside interprofessional rounds were "improves communication between nurses and physicians," "improves awareness of clinical issues need to be addressed," and "improves team-building between nurses and physicians;" lowest-ranked benefits were "decreases patients' hospital length-of-stay" and "improves timeliness of consultations." Nursing staff reported more favorable ratings compared to both attending and resident physicians for all 16 items (all *p*-values <0.05); the rank order between respondent groups showed a high degree of correlation (*r*=0.92–0.96, *p*<0.001). Highest-ranked barriers were "nursing staff have limited time," "time required for encounters," and "coordinating the start time of encounters;" lowest-ranked barriers were "patient lack of comfort" and "physicians' lack of bedside skills." The rank order between respondent groups showed variable correlation (nurse-attending 0.62, nurse-resident 0.76, attending-resident 0.82).

CONCLUSIONS: Nursing staff were more likely to report positive perceptions about the benefits of bedside interprofessional rounds than resident and attending physicians. Overall, the greatest perceived benefits related to improved communication. Standardization of the rounding process and patient inclusion in conversations may allow knowledge assimilation regarding care plans most important to patient care and disposition. Reasons for nurses' more positive perceptions than physicians are unclear but may reflect their experience with benefits or professional culture of this patient-centered activity. Time was the common theme in the highest-rated barriers, prompting consideration of addressing modifiable systems factors to increase this activity; cost-neutral measures such as tailoring nursing and physician schedules, modifying care coordination rounds, pre-scheduling patient rounding times, and geographic localization of patients and providers may attenuate this barrier. Further investigation into the impact of bedside interprofessional rounds on patient satisfaction and outcomes are necessary to validate widespread dissemination.

BEDSIDE ROUNDS IN THE ERA OF COMPETENCY-BASED EDUCATION: A WORKPLACE-BASED STRATEGY FOR FEEDBACK AND REFLECTION Jed Gonzalo^{1,2}; Brian S. Heist²; Brian Duffy^{3,2}; Liselotte Dyrbye⁴; Mark J. Fagan⁵; Gary S. Ferenchick⁶; Heather Harrell⁷; Paul Hemmer⁸; Walter N. Kerman⁹; Jennifer R. Kogan¹⁰; Colleen M. Rafferty¹; Raymond Y. Wong¹¹; Michael Elnicki². ¹Penn State College of Medicine, Hershey, PA; ²University of Pittsburgh School of Medicine, Pittsburgh, PA; ³University of Minnesota School of Medicine, Minneapolis, MN; ⁴Mayo Clinic College of Medicine, Rochester, MN; ⁵Alpert Medical School of Brown University, Providence, RI; ⁶College of Human Medicine, Michigan State University, East Lansing, MI; ⁷University of Florida College of Medicine, Gainesville, FL; ⁸Uniformed Services University of the Health Sciences, Bethesda, MD; ⁹Yale University School of Medicine, New Haven, CT; ¹⁰Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; ¹¹Loma Linda University School of Medicine, Loma Linda, CA. (*Tracking ID #1937769*)

BACKGROUND: Feedback and reflection are two strategies integral to competency-based medical education and trainee development. These methods are best employed in authentic workplace-based settings, opportunities which are not well described in

the literature. Bedside rounds have been highlighted as an ideal venue for observation, feedback, and reflection, and the literature suggests methods for implementing these strategies, but actual strategies used to deliver feedback and team-based reflection by current-day bedside teachers has not been described. We sought to understand the content and timing of feedback and team-based reflection provided by bedside teachers in the context of patient-centered bedside rounds.

METHODS: In 2010, a qualitative thematic analysis of transcripts from digitally recorded, one-on-one telephone interviews with experienced bedside teachers (*n*=34) was performed. Co-investigators from 10 U.S. institutions were recruited and asked to identify participants who had: 1) served as inpatient attending physician at least 2 weeks in the prior 2 years, and 2) performed "bedside rounds" while inpatient attending, defined as: "The team of providers, including at least one resident and attending physician, presenting the patient's history or reviewing one physical exam component, in addition to discussing the diagnosis/management at the bedside in the patient's presence." Interviews consisted of closed- and open-ended questions; questions related to feedback were designed from frameworks identified in the literature. For questions related to reflection, defined as "...analyzing an experience for the purposes of learning or improve practice," no studies were identified, therefore an inductive approach was used. Two investigators analyzed transcripts independently, with regular adjudication sessions to modify the codebook, followed by theme extraction. The study was exempt from review by all Institutional Review Boards.

RESULTS: Participants averaged 14 years of academic experience and 50 % were associate/full professor. Positive feedback about physical exam skills or clinical decision-making occurred during bedside encounters, while positive or constructive team-based feedback occurred immediately following encounters; individualized constructive feedback occurred following rounding sessions in private locations. Team-based reflection occurred immediately following bedside encounters and related to commonplace "teachable moments" more so than less frequent, emotionally-charged events. Three content areas related to team-based reflection were identified: (1) patient characteristics/emotions, (2) trainee actions/emotions, and, (3) attending physician role modeling.

CONCLUSIONS: Bedside teachers use bedside rounds as a workplace-based opportunity to stimulate feedback and team-based reflection with medical trainees. Bedside rounds provide authenticity as bedside activities allow assessments of trainees' performance and skills in the context of real-time patient encounters. As demonstrated by participants, reflection can be used to promote cognitive and humanistic growth of trainees. Although reflection has been identified in the literature, no prior work has identified a taxonomy of events triggering reflection. Amidst current-day pressures of inpatient medicine, these content and timing-related strategies for feedback and reflection could assist in faculty development efforts geared toward competency-based education.

BEHAVIORAL ECONOMICS-INFORMED INTERVENTIONS TO REDUCE INAPPROPRIATE ANTIBIOTIC PRESCRIBING: A PILOT CLUSTER RANDOMIZED TRIAL Stephen D. Persell¹; Jeffrey A. Linder²; Mark W. Friedberg^{3,2}; Daniella Meeker⁴; Elisha M. Friesema¹; Andrew J. Cooper¹; Craig R. Fox⁵; Noah J. Goldstein⁵; Jason N. Doctor⁶. ¹Northwestern University, Chicago, IL; ²Brigham and Women's Hospital, Boston, MA; ³RAND, Boston, MA; ⁴RAND, Santa Monica, CA; ⁵UCLA, Los Angeles, CA; ⁶University of Southern California, Los Angeles, CA. (*Tracking ID #1938251*)

BACKGROUND: Physicians often use antibiotics for acute respiratory infections (ARIs) when they are not indicated. Interventions to reduce inappropriate prescribing have been only modestly successful.

METHODS: In preparation for a larger, multi-site trial, we performed a pilot cluster-randomized controlled clinical trial with physician as the unit of randomization and office visit as the unit of analysis to evaluate different behavioral economic and social psychological approaches to reduce inappropriate antibiotic prescribing. Physicians and a nurse practitioner at a single large urban academic internal medicine practice were enrolled and randomized within a $2 \times 2 \times 2$ factorial experiment. Qualifying ARI visits triggered each intervention. The interventions were: 1) Accountable Justifications: when prescribing an antibiotic for an ARI, clinicians are prompted to record an explicit justification that appears in the patient electronic health record (EHR); 2) Suggested Alternatives: through computerized clinical decision support, clinicians prescribing an antibiotic for an ARI receive a list of non-

antibiotic treatment choices prior to completing the antibiotic prescription; and 3) Peer Comparison: each provider's rate of inappropriate antibiotic prescribing relative to top-performing peers is provided periodically by email. All providers completed an on-line educational module about ARI treatment at the start of the intervention period. The primary outcome was the rate of antibiotic prescribing for visits with an ARI diagnosis for which antibiotics are not indicated (e.g. acute bronchitis, unspecified upper respiratory infection). Secondary endpoints were prescribing rates for acute sinusitis or pharyngitis, and prescribing rates for all other respiratory infections or symptoms of respiratory infection. We excluded patients with major comorbidities (e.g., COPD, cirrhosis) or a concomitant diagnosis that suggested a non-respiratory-tract bacterial infection (e.g., cystitis). EHR-data was used to measure outcomes during the year prior to and during a 1-year intervention period. We used mixed models to assess intervention effects accounting for fixed effects for patient age and providers' prior prescription rate and random provider effects.

RESULTS: 28 of 38 providers participated. Antibiotic prescribing fell in the intervention year for non-antibiotic-appropriate ARI diagnoses (from 24.7 to 4.6 %), for sinusitis/pharyngitis (from 45.1 to 35.1 %), and for all other respiratory diagnoses or symptoms of infection (43.5 to 31.5 %; all $p < 0.001$). There were no significant differences in the primary outcome for any of the interventions. Suggested Alternatives led to a lower odds of antibiotic prescribing for sinusitis/pharyngitis, odd ratio (OR) 0.35, (95 % confidence interval [CI] 0.22–0.58); and for all respiratory visits combined (OR 0.72 [95 % CI 0.54–0.96]). Peer comparisons led to lower odds of antibiotic prescribing for all respiratory visits combined (OR 0.73 [95 % CI 0.53–0.995]). There was no increase in the proportion of total ARI visits within the potentially antibiotic appropriate category or other ARI diagnosis/symptom category.

CONCLUSIONS: The conduct of this study had a large impact on antibiotic prescribing behavior. Given the moderately low baseline rate and the possible Hawthorne effect, the prescribing rate for the primary outcome may have reached a floor below which adding additional interventions could not reduce it further. Since this was a single site, this widespread decline in prescribing may have been due communication between intervention and control group providers that led to attitudinal or cultural changes more broadly within the practice. Evidence of gaming the system (e.g., changing diagnosis codes to make antibiotic prescribing appear more appropriate) was not observed. An ongoing, larger, practice-randomized trial will help elucidate the effects of these interventions on provider behavior.

BETTER INFORMED PATIENTS ARE LESS LIKELY TO CHOOSE PERCUTANEOUS CORONARY INTERVENTION FOR STABLE ANGINA Michael B. Rothberg¹; Senthil K. Sivalingam²; Reva Kleppel²; Bo Hu¹; Marc Schweiger². ¹Cleveland Clinic, Cleveland, OH; ²Baystate Medical Center, Springfield, MA. (Tracking ID #1937449)

BACKGROUND: Patients with chronic stable angina often believe that percutaneous coronary intervention (PCI) will prevent a myocardial infarction or extend life, even though their cardiologists do not believe this. The extent to which cardiologists contribute to this misperception is unknown. One possibility is that patients do not receive complete information about the procedure. We reviewed consent conversations to assess the level of informed decision making and its association with choosing to have PCI.

METHODS: Using the Verilogue Point-of-Practice Database, which includes visits with >600 physicians in nine geographic regions throughout the U.S., we searched outpatient/non-acute visit transcripts audio-taped between August 2008 and August 2012 for mention of PCI, cardiac catheterization, angiogram or stent placement. We limited transcripts selected to those that included consent discussions with a cardiologist. Two investigators reviewed each transcript to identify the 7 elements of decision making required for a complex medical decision, using the framework developed by Braddock, et. al. The 7 elements include discussion of the 1) patient's role in decision making, 2) nature of the decision 3) the alternatives 4) pros and cons of the alternatives 5) uncertainties associated with the decision 6) assessment of the patient's understanding and 7) exploration of patient preference. We also assessed the cardiologists' recommendation and the patient's decision regarding catheterization and PCI (cath/PCI). Because these procedures are usually done at the same time, patients give consent for both procedures at once. We assessed the association between the

decision to undergo cath/PCI and specific elements of informed decision making, angina severity, and physician recommendation. Finally, we assessed the association between completeness of informed decision making, defined as the number of elements of informed decision making present in the conversation, and the patient's decision to undergo cath/PCI in a logistic regression model.

RESULTS: The final dataset included 27 cardiologists in conversations with 60 patients (median two patients per cardiologist, range 1 to 6). Cardiologists were all male, had been in practice for an average of 20.5 years (range 8 to 34), and 2/3 belonged to a private office-based group practice. Mean patient age was 66 years, 70 % were male and 75 % were white. Of the 60 discussions, 4 (7 %) included all 7 elements of informed decision making; 28 % met a more restricted definition of procedure, alternatives and risks. In just over half (52 %) there was some discussion of the patient's role in decision making. Discussion of the clinical issue was present in 97 % of discussions, but discussion of alternatives (27 %) and uncertainties (10 %) were uncommon. Assessment of patient understanding and exploration of preferences each occurred in 65 % and 73 % cases, respectively. At the end of the visit, 44 (73 %) patients chose to undergo PCI. Physicians made recommendations in 49 cases and patients followed the recommendations in 90 % of cases. In univariate analysis, the proportion of patients choosing cath/PCI was lower when there was discussion of 1) uncertainty associated with the decision (17 % vs. 80 %, $p < 0.01$), 2) the patient's role in decision making (61 % vs. 86 %, $p = 0.03$), and 3) discussion of the alternatives (31 % vs. 89 %, $p = <0.01$). The proportion choosing cath/PCI was lower, but not statistically so, when the physician assessed patient understanding (67 % vs. 86 %, $p = 0.11$) and explored patient preference (68 % vs. 88 %, $p = 0.13$). Anginal symptoms were present in 81 % of patients, but limited activity in only 28 % of patients. Presence of symptoms was not statistically associated with choosing cath/PCI ($p = 0.44$), but patients whose symptoms limited activity were more likely to choose cath/PCI (94 % vs. 71 %, $p = 0.06$). In multivariable analysis, better informed patients were more likely to choose not to undergo cath/PCI (OR=2.7 for each additional element of informed decision making, 95 % CI 1.2 to 6.2, $p = 0.02$).

CONCLUSIONS: In consent conversations between cardiologists and patients with stable angina, informed decision making is often incomplete. More complete discussions are associated with patients choosing not to undergo cath/PCI. Efforts to involve patients in shared decision making for cath/PCI might also reduce resource utilization.

BLOOD PRESSURE CONTROL IN DIABETIC PATIENTS AT FEDERALLY QUALIFIED HEALTH CENTERS: THE IMPACT OF OFFICE-GUIDELINES APPLIED TO PRACTICE (OFFICE-GAP) PROGRAM Ade B. Olomu¹; Bikki Gautam¹; Bethany Buda¹; Wei-Wen Hsu³; Gurpreet Chahal¹; David Todem²; Alexis Therman¹; Esha R. Kumar¹; Margaret Holmes-Rovner⁴. ¹Michigan State University, East Lansing, MI; ²Michigan State University, East Lansing, MI; ³Michigan State University, East Lansing, MI; ⁴Michigan State University, East Lansing, MI. (Tracking ID #1932917)

BACKGROUND: The most important intervention for preventing death and adverse cardiovascular (CVD) outcomes is adequate control of blood pressure (BP) in diabetic (DM) patients. Unfortunately, diabetic patients with hypertension (HTN) are often not adequately controlled and HTN management is less intensive in patients with DM. HTN is particularly burdensome in low-income groups, where the prevalence of uncontrolled HTN is higher than the general population. Federally Qualified Health Centers (FQHCs) provide care for low income and medically underserved populations. Objectives: 1) to determine the rate and predictors of Blood Pressure (BP) control in patients with DM and HTN in FQHCs. 2) determine the impact of a CVD secondary prevention intervention- Office Guidelines Applied to Practice (Office-GAP) Program on BP control in FQHCs.

METHODS: The Office-GAP study is a two-center intervention and control study designed to improve cardiovascular care for minority and low-income populations in outpatient clinical settings. Intervention included provider training, patient education in a group visit, and use of Office-GAP tools/checklist and patient decision aids during office visits. After a group visit, patients followed up with physician visits using GAP tools. We performed chart abstraction of all patients with HTN, CVD and/or DM from September 2010 to

Dec 2012 in 2 FQHCs. Hypertension was defined as Systolic BP>140 mmHg (>130 mmHg in DM patients) and diastolic BP>90 mmHg (>80 mmHg in DM patients). Multivariable logistic Regression was used to identify potential predictors of BP control.

RESULTS: Of 242 patients identified, 188 had DM, and 191 had HTN, 146 had HTN and Diabetes. One hundred patients were in the intervention (Office-GAP) arm and 142 in the control arm. At baseline, 32.79 % (60/183) and 26.76 % (38/142) of all patients with HTN without diabetes and HTN patients with DM had their BP controlled respectively. We found that diabetic patients enrolled in the Office GAP Intervention were more likely to have their BP controlled at 6 months (OR=2.70, $p=0.048$) compared to control patients after adjusting for relevant clinical variables. In addition, the logistic regression model revealed that whites (OR 2.6, $p=<0.001$) and other races (Hispanics, Nepalese, Somali) (OR=1.685, $p=0.031$) were more likely to have their BP controlled compared to black patients. Furthermore, older age (OR 0.98, $p=0.014$) and patients with higher Charlson Index (OR 0.85, $p=0.002$) were found to be marginally less likely to have their BP controlled.

CONCLUSIONS: We found that the majority of patients attending FQHCs do not have their BP controlled. BP control among diabetics was substantially less frequent than in nondiabetic patients. Black patients were less likely to have their BP controlled compared to other races. The Office-GAP Intervention improved rates of BP control for diabetic patients in FQHCs. The Office-GAP Program could serve as a model for improving care for patients in outpatient clinical settings. Further studies are needed to determine the effectiveness and cost-effectiveness of this approach.

BUILDING COMMUNITY TRUST THROUGH QUALITY ASSURANCE OF MALARIA DIAGNOSIS AND MANAGEMENT AT A RURAL CLINIC IN UGANDA

Sae-Rom Chae¹; Toni Biskup²; Sara Heinert²; Janet Lin^{2,3}. ¹University of Illinois at Chicago College of Medicine, Chicago, IL; ²University of Illinois at Chicago College of Medicine, Chicago, IL; ³University of Illinois at Chicago School of Public Health, Chicago, IL. (*Tracking ID #1933920*)

BACKGROUND: At a rural primary care clinic in Uganda, a patient survey indicated that the community members feel it provides a high, trustworthy quality of care. However, no quality assurance studies have been conducted to characterize the quality of care provided. Malaria remains a leading cause of morbidity and mortality in Uganda. Widespread efforts have been made by the public sector to build capacity in diagnosis and treatment of the disease. This study aims to evaluate the quality of care provided by the clinic by examining malaria diagnosis and treatment patterns and assessing the degree of adherence by the clinic staff to national malaria treatment guidelines. Study objectives: 1. Determine how malaria is being diagnosed and consequently managed among a sample of a Ugandan rural clinic patient population. 2. Assess diagnostic methods and appropriate classification of severity of disease. 3. Evaluate malaria treatment regimens as appropriate based on 2012 Ugandan treatment guidelines. 4. Consider the quality of malaria care provided and whether the clinic is providing trustworthy care to the community.

METHODS: A retrospective chart review of patients seen at a rural clinic in Uganda in a 12-month period from June 2012–June 2013 was conducted to determine the rates of appropriate diagnosis and treatment of malaria. All patients with blood smears done on a Monday, Wednesday, or Friday were included. De-identified data on demographics, presenting symptoms, given diagnoses, medications, blood smear results, and notes on management decisions was recorded in a database. Variables were then coded numerically for each record and a second individual re-coded 10 % of the charts for verification. After excluding charts with missing data points, a final sample of 1001 patients was analyzed using SAS and Microsoft Excel.

RESULTS: Of the total 390 positive blood smears, only three patients (0.8 %) were not started on malaria medication. Of patients documented to have a negative smear (572 or 57.1 %), 83 (14.5 %) were started on malaria treatment. 198 (50.8 %) of the positive smears were among adult patients above the age of 17 years, three of which showed hyperparasitemia. Of these, 1 was referred for higher level care, 1 was started on second-line quinine treatment, and the third was started on alternative first-line treatment. Five patients that were documented to have a diagnosis of malaria and a presenting symptom of seizures, qualifying them as severely ill, were not started on parenteral treatment or referred for higher-level care. Of the total 21 patients started on second-line

quinine-based treatment, 11 (52.4 %) had a documented and appropriate indication. Of all patients documented to have a positive smear and placed on appropriate malaria treatment, 7 (1.8 %) were concurrently started on an antibiotic (i.e. doxycycline, clindamycin), documented as malaria treatment.

CONCLUSIONS: Overall, clinic staff demonstrate a heightened index of suspicion for malaria infection, appropriate for a highly endemic area. Nearly all patients with positive diagnostic tests were started on treatment. A small number were started on empiric treatment despite a negative test. Investigating the reasons for this would be worthwhile in order to prevent over-treatment. Most of the patients experiencing serious, complicated malarial disease, including those with hyperparasitemia, were not treated according to national guidelines with intravenous quinine. Further training may be needed in identifying and documenting cases of severe malarial illness and the appropriate management sequence. This may significantly impact mortality and morbidity. A knowledge assessment of the staff informed by detailed chart reviews and process mapping in the future may be helpful in delineating where intervention might be the most suitable. Additionally, second-line treatment is being over-prescribed or indications are not adequately documented. If the former is occurring, this may affect drug resistance patterns in an unfavorable manner. Lastly, antibiotic regimens are being prescribed to supplement malaria treatments which warrants additional investigation. Without appropriate indication, this practice may contribute to antimicrobial resistance and unnecessary medication side effects. The national guidelines do not discuss the indications for concurrent antibiotic treatment. In summary, improvement is needed in the areas of classifying severity of malarial illness and consequent management, indications for the various types of treatment, and possible bacterial co-infection with indication for additional treatment.

BUILDING EQUITY IMPROVEMENT INTO QUALITY IMPROVEMENT: REDUCING SOCIOECONOMIC DISPARITIES IN COLORECTAL CANCER SCREENING AS PART OF POPULATION HEALTH MANAGEMENT

Seth A. Berkowitz¹; Sanja Percac-Lima¹; Jeffrey M. Ashburner¹; Yuchiao Chang¹; Adrian Zai¹; Wei He¹; Richard W. Grant²; Steven J. Atlas¹. ¹MGH, Boston, MA; ²Kaiser Permanente, Oakland, CA. (*Tracking ID #1921347*)

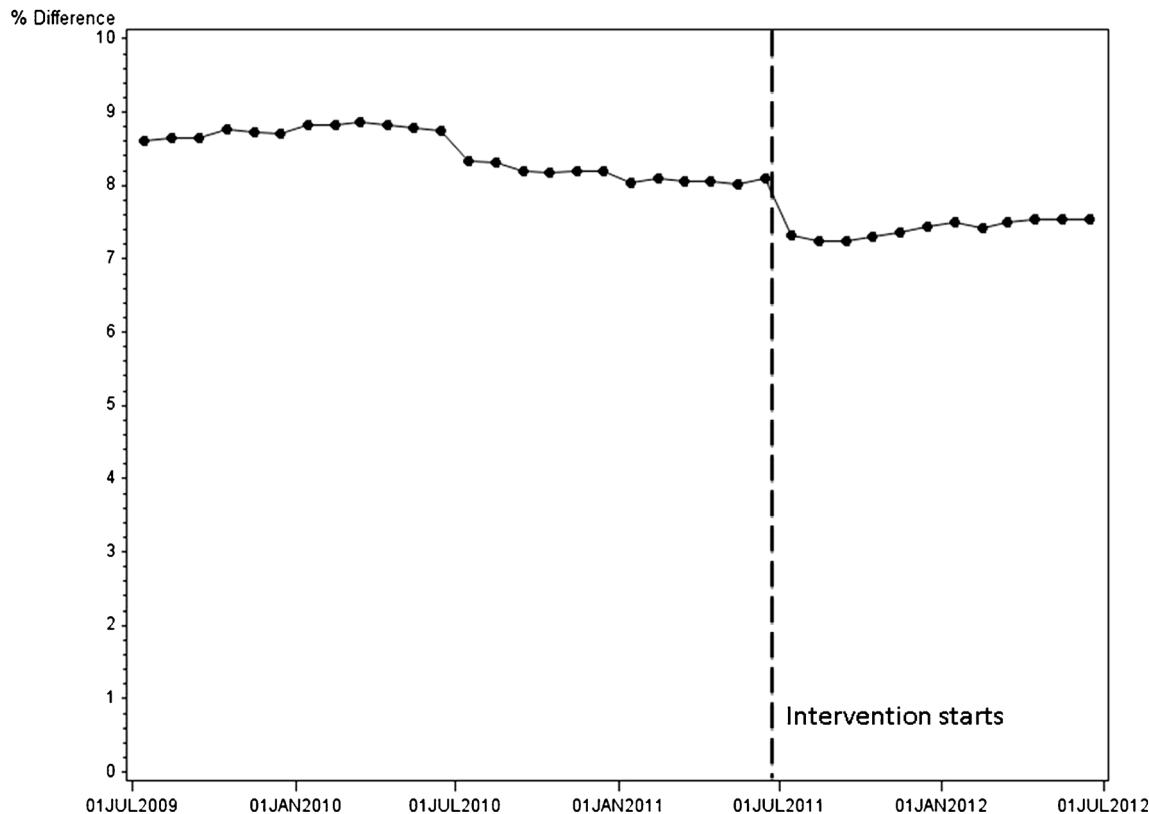

BACKGROUND: Improving colorectal cancer (CRC) screening rates for patients from socioeconomically disadvantaged backgrounds is a recognized public health priority. We tested the hypothesis that implementation of a system-wide screening intervention could increase overall screening rates while also decreasing screening disparities.

METHODS: In June 2011, we implemented the Technology for Optimizing Population Care (TopCare) intervention to improve CRC screening for all eligible patients in our 18-practice primary care network. The TopCare intervention system electronically identifies patients overdue for screening and contacts them by letter or telephone scheduler, with or without physician involvement. Patients identified by automated algorithm as high risk for non-completion are entered into a more intensive program of patient navigation. Using ≤high school (HS) diploma as our marker for socioeconomic disadvantage, we investigated whether baseline differences in CRC screening completion rates between ≤HS diploma vs. >HS diploma patients narrowed after implementation of TopCare. We used an interrupted time series analysis to compare monthly CRC screening completion rate disparities in the 2 years prior to implementation (June 15, 2009–June 14, 2011) and 1 year after implementation (June 15, 2011–June 14, 2012).

RESULTS: At the beginning of the study period, 71 % of 52,011 eligible patients had completed screening, while by the end 74 % of 54,572 eligible patients had completed screening ($p<.001$). Although CRC screening completion remained higher in >HS diploma vs. ≤HS diploma patients in June 2009 (74 % vs. 66 %, $p<.001$) and June 2012 (77 % vs. 70 %, $p<.001$), the difference in screening rates decreased from 8.6 to 7.3 % over this 3-year period (Figure). In our interrupted time series analysis accounting for secular trends, the introduction of TopCare was associated with a significant decrease in the CRC screening disparity ($p<.001$). The decrease represents approximately 150 more ≤HS diploma patients with complete CRC screening each month than without the intervention, an improvement that would have taken approximately 27 additional months to occur had pre-intervention trends continued.

CONCLUSIONS: A multifaceted population management intervention sensitive to the needs of vulnerable patients narrowed disparities in CRC screening while also increasing overall screening rates. Embedding interventions for vulnerable patients within larger population-based systems represents an effective approach to increasing overall care quality while simultaneously decreasing disparities.

Differences in CRC Screening Completion by Educational Attainment

BUILDING THE INFRASTRUCTURE TO SUPPORT ACCOUNTABLE CARE PAYMENT MODELS: LESSONS FROM THE FIELD Maria Han¹; M. Susan Ridgeley²; Cheryl Damberg². ¹UCLA, Los Angeles, CA; ²RAND, Santa Monica, CA. (*Tracking ID #1940916*)

BACKGROUND: The accountable care organization (ACO) is a novel payment and delivery system innovation aimed at improving value in health care. As hundreds of healthcare organizations have entered into ACO contracts, they have had to make significant structural and organizational changes, including expanding capabilities to deliver population-based care and forging integrated provider relationships. Despite the scale and complexity of the changes required in transitioning to the ACO model, there is little known or reported about how to optimally design an ACO. Given the substantial investment and risk associated with ACO formation, the future success of the ACO movement will require effectively capturing, disseminating, and replicating the lessons learned by early ACOs. To that end, the objective of this study is to delineate the major types of innovations implemented by provider organizations in their endeavors to become successful ACOs.

METHODS: The accountable care organization (ACO) is a novel payment and delivery system innovation aimed at improving value in health care. As hundreds of healthcare organizations have entered into ACO contracts, they have had to make significant structural and organizational changes, including expanding capabilities to deliver population-based care and forging integrated provider relationships. Despite the scale and complexity of the changes required in transitioning to the ACO model, there is little known or reported about how to optimally design an ACO. Given the substantial investment and risk associated with ACO formation, the future success of the ACO movement will require effectively capturing, disseminating, and replicating the lessons learned by early ACOs. To that end, the objective of this study is to delineate the major types of innovations implemented by provider organizations in their endeavors to become successful ACOs.

RESULTS: One-year following grant funding, eight of the 18 organizations had implemented interventions aimed at redesigning clinical care (the remaining grantees focused on building IT infrastructure). While organizations executed a diversity of interventions in care redesign, most of them focused on delivering care that was increasingly coordinated, team-based, and patient-centered. Almost all (7/8) of the grantees instituted programs to improve care coordination, particularly across patient transitions. Six of the grantees implemented team-based care approaches, including utilization of physician extenders, development of disease-oriented teams, and implementation of the patient-centered medical home model. Finally, all of the organizations emphasized patient-centered care through the promotion of patient education initiatives, group appointments, extended office hours, and social needs assessments.

CONCLUSIONS: Many health systems currently face the challenge of moving the ACO from a theoretical concept to an “on the ground” reality. While “nascent” ACOs have experimented with hundreds of unique approaches to ACO development, this study is one of few reports on their experiences and common themes in implementation. As such, the findings of this study may prove useful in understanding what infrastructure investments will create the right capabilities for delivering accountable care.

BUYING TIME: QUALITY IMPROVEMENT PROJECT TO DECREASE PATIENT CALLS FOR MEDICATION REFILLS IN A RESIDENT RUN CONTINUITY CLINIC Amanda Lerner^{1,2}; Shveta Gandhi^{1,2}; Diane Resnick¹; John T. Connor¹; Rowena Garcia¹; Laurie Hudson-Bonner¹; Joann Sabados-Carolina¹; Andrea Palisi¹; Michael P. Carson^{1,2}. ¹Jersey Shore University Medical Center, Neptune, NJ; ²Rutgers-Robert Wood Johnson Medical School, Piscataway, NJ. (*Tracking ID #1913297*)

BACKGROUND: The resident run continuity clinic noted a large volume of calls/faxes for medication refill requests, and we estimated that each required a minimum

of 15 min of staff time to complete. In addition, running out of medication poses a potential risk to patient well-being. Objectives: utilize the Plan-Do-Check-Act quality improvement process to quantify and identify Refill Request patterns, develop an education plan, and assess the efficacy of the plan to reduce these requests/improve patient safety.

METHODS: Pre-Education Data: Nurses logged each Refill Request over 3 months noting time since the last office visit, and method of request (patient walking in, patient/pharmacy call to the prescription line vs. main clinic number, pharmacy fax to one of two machines). An action plan was developed and disseminated to the practitioners. Four months later, a second assessment was completed (Post-Education Reassessment).

RESULTS: Pre-Education Data: 17.8 Refill Requests/day (765/43 days). Patients typically return after 12–24 weeks, but 61 % of the requests were received within 8 weeks of a patient's last visit suggesting physicians were not providing enough refills. Twenty-five percent were due to patients missing visits, and 7 % were to clarify/correct a prescription. Pharmacies generated eight messages per day, and sent 278 faxes. Action Plan: Caregivers were instructed to objectively confirm remaining refills (view pill bottle, or review photocopy of the prior prescription in the chart), and provide enough refills until the next visit plus one extra month ("Month Plus 1" policy). Patients were advised to bring all bottles to each visit, and pharmacies were asked to fax all Requests to a single machine located in our clinic. Reassessment: 3.3 requests/day (110/33 days), an 81 % decrease in the average volume of daily requests; only 10 % due to physician error and 64 % due to patient issues. Pharmacy calls dropped by 90 % to 33 (~1/day). Patient calls dropped from 3/day to 2/day. As we had 33 observations from the Post-Education phase, a matched analysis required us to use only 33 of the 43 Pre-Education observations. To avoid overestimating the effect, we first compared the 33 lowest Pre-Education data points to the Post-Education values yielding an average decrease of 6.2 requests/day [95 % CI (4.8)]. The analysis using the 33 highest Pre-Education values yielded a decrease of 19 requests/day [95 % CI (12,26)]. Estimating 15 min per Request, this the daily staff workload decreased by at least 1.5, and up to 4.8 h a day.

CONCLUSIONS: A simple caregiver and patient education program facilitated an 81 % decrease in the volume of calls/faxes for medication refills in this resident-run continuity clinic. Patients often told resident physicians they had refills remaining, however not enough to get them to the next visit. Therefore, objectively determining the number of refills and the "Month Plus 1" policy are likely responsible for the majority of the decrease, and they improve patient care by decreasing the chance that a patient will be without their medication. On average, the 14.5 fewer requests/day decreased the time burden on an already limited clinical staff by 3.6 h per day. The staff is satisfied, and a third survey confirmed patients missing visits as the primary reason for Refill Requests. Future efforts will focus on communicating with patients to improve attendance at scheduled visits.

CALLING "DR. GOOGLE"....: DOES TECHNOLOGY FILL THE GAP CREATED BY THE PRENATAL CARE VISIT STRUCTURE? *Jennifer Kraschnewski¹; Cynthia H. Chuang¹; Erika Poole¹; Tamara Peyton¹; Ian Blubaugh¹; Alyssa Feher²; Madhu Reddy¹. ¹Penn State Hershey Medical Center, Hershey, PA; ²Cumberland/Perry Tapestry of Health, Carlisle, PA. (Tracking ID #1936600)*

BACKGROUND: The structure of prenatal care has changed little over the past several decades despite the rapid evolution of technology. Little is known about how pregnant women engage with technologies (e.g. websites, smartphone apps) and the interface between these tools and medical care, especially for women of lower socioeconomic status. We sought to understand the role of technology in pregnancy through a qualitative study with women enrolled in the Women, Infants and Children (WIC) program.

METHODS: We recruited pregnant women ages 18 and older who owned a smartphone at a WIC clinic in central Pennsylvania. Four focus groups were conducted with a total of 25 women. The focus group guide included questions about the positive experiences and challenges women encountered during their current pregnancy, sources of information, and whether they used their smartphones or other technology for pregnancy-related information. Sessions were audiotaped and transcribed. Two members of the research team independently analyzed each transcript, using a thematic analysis approach. Themes related to the topics discussed were identified, for which there was full agreement.

RESULTS: Three major themes emerged. First, the prenatal visit structure was not patient-centered. Women commented that the first visit occurs too late, with too few

visits early in pregnancy, when women had the most questions for their doctors: "...They expected me to wait 13 weeks until I had a conversation with my doctor." "I know we can't change the healthcare system... but on your first appointment, they say, 'We'll see you in 8 weeks...' and uh... That's 2 months! What am I going to do?" Even when women did see their doctor, the materials they received were viewed as unhelpful: "Today they gave me a whole bag of pamphlets and flyers and didn't explain or go over them with me... and now I have to go home and try to go through them, while I have a kid running around... and when you're a new mom, that's overwhelming." Second, women turned to technology to fill gaps, including using Google and smartphone applications (i.e. Babycenter): "I found myself using Dr. Google, because I couldn't get an appointment until I was 14 weeks. They just wouldn't see me." Turning to technology was viewed to be a generational approach: "It's interesting cause I think that the generation before us counted a lot on our mom and our sisters to give advice. And now it's technology..." Lastly, women reported that technology, although frequently used, was not without limitations: "...so sometimes you can Google something, like when I was having my round ligament pain for the first time... some things that came up were terrifying... you want to go to the ER right away! You definitely have to be careful and smart about your Google searches."

CONCLUSIONS: The current prenatal care visit structure is not patient-centered in that it does not allow women to seek advice when they want it the most. A generational shift has occurred, resulting in pregnant women turning to the Internet to fill this gap, which requires significant skills to navigate for useful information. Until systems-based changes are made to the prenatal care visit structure, primary care providers may be called on to assist our patients early in pregnancy seek the information they want and to become better consumers of pregnancy-related information on the Internet.

CAN AN IN-HOSPITAL CARE TRANSITION INTERVENTION IMPROVE PATIENT EXPERIENCE IN THE SAFETY NET? A RANDOMIZED CONTROLLED TRIAL *Brian Chan¹; L. E. Goldman¹; Urmimala Sarkar¹; Michelle Schneidermann²; Jeffrey Critchfield²; Margot Kushel¹. ¹UCSF/SFGH, San Francisco, CA; ²UCSF/SFGH, San Francisco, CA. (Tracking ID #1937181)*

BACKGROUND: Patient experience measures are important markers of quality, as evidenced by use of the Hospital Consumer Assessment of Healthcare Provider Scores (HCAHPS) and Care Transitions Measures (CTM-3) for hospital value-based purchasing reimbursement. Patient experience scores are lower in safety-net hospitals than non safety-net hospitals; this gap is widening. We assessed the effect of a nurse-led, language concordant, hospital-based care transition intervention on patient experience in older adults hospitalized at a safety-net hospital.

METHODS: We randomized, and stratified by language (English, Spanish or Chinese), 700 inpatients age 55 and older who were inpatients at an academic urban safety-net hospital. The intervention consisted of usual care and 1) inpatient visits by a language concordant nurse that provided individualized post-hospitalization education and 2) post-discharge phone calls by a nurse practitioner to reinforce the care plan and to address acute complaints. Language concordant research assistants, blinded to randomization group, measured HCAHPS nursing, physician, medication, and discharge information domains and CTM-3 scores at 30 days after hospital discharge.

RESULTS: Of 685 participants who survived to 30 days, 90 % ($n=617$) completed follow-up research interviews. Mean age was 66 years; 24 % were African American; 19 % were White; 32 % were Asian and 19 % Latino. Over half (61 %) of interviews were conducted in English, 24 % in Chinese and 15 % in Spanish. Over a third of participants noted limited English proficiency, and 51 % met criteria for low health literacy. Study nurses spent an average of 157 min with the intervention participants. There were no statistically significant differences in mean HCAHP domain scores and CTM-3 scores between the intervention and control groups (Table 1); no significant differences were seen between groups when results were stratified by language.

CONCLUSIONS: The failure of a language concordant nurse-led intervention to improve patient experience scores suggests that these measures are difficult to improve using hospital-based interventions. Thus, caution should be exercised when linking hospital-based reimbursement to improved HCAHPS and CTM scores. Further work is necessary to identify interventions that can improve patient experience and care transitions measures.

Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) Mean Domain and Care Transitions Measure (CTM-3) Scores assessed at 30 days

CAN PARTICIPATION IN COMMUNITY ENGAGEMENT ACTIVITIES REDUCE DISTRUST IN MEDICAL RESEARCHERS AMONG DIVERSE COMMUNITIES: RESULTS FROM THE COMMUNITY ENGAGEMENT AND RESEARCH PROGRAM OF THE UCLA CTSI Nazleen Bharmal¹; Li-Jung Liang¹; Sitaram Vangala¹; Stefanie D. Vassar¹; Ibrahima Sankare¹; Loretta Jones²; Keith C. Norris¹; Martin F. Shapiro¹; Arleen Brown¹. ¹UCLA, Los Angeles, CA; ²Healthy African American Families II, Los Angeles, CA. (*Tracking ID #1938942*)

BACKGROUND: Racial/ethnic minorities are not adequately represented in medical research studies. One explanation, supported by scientific literature, is that distrust in research and the medical community may impede recruitment of racial/ethnic minorities into medical research studies. Among the goals of the UCLA Clinical and Translational Science Institute's Community Engagement and Research Program (CERP) are to enhance the community's trust in health research by promoting knowledge sharing between community and academia and strengthening both community and academic infrastructure for sustainable partnered research. To achieve these goals, the CERP has sponsored or co-sponsored a series of large symposia and smaller workshops on clinical research, public health topics, and community engagement. To assess levels of trust among community members who participate in CERP events, we surveyed attendees at every event held over a 14 month period. **METHODS:** Between June 2012 and August 2013, participants at CERP events were asked to respond to four survey items: 1) "If a medical researcher asked you to participate in a medical research study, you trust that he/she would provide you with a full explanation of the study," 2) "A medical researcher would not ask you to participate in a research study if he/she thought it would harm you," 3) "If you participate in a medical research study, you trust that the medical researcher will make sure that you fully understand the consent form before you sign it," and 4) "If you, or people in your community, choose to participate in medical research, do you feel that the medical researcher will always try to protect you from unnecessary risk?" The written items were self-administered in English or Spanish at the end of each event. The response choices, distributed across a 4 point Likert scale, were dichotomized as "strongly agree/agree" vs. "disagree/strongly disagree/don't know." We developed a distrust index with a score ranging from 0 to 4 as our main outcome measure. Only participants who responded to at least three of the four questions were assigned a distrust index score. Data from events was aggregated by the quarter of the year during which the event occurred. We compared distrust scores across all quarters using linear mixed-effects regression model, adjusted for participant's demographic characteristics and accounting for heterogeneity of variance across types of community event. We present the estimated difference between the distrust index scores using model contrast for 2012 Q2 vs. 2013 Q3.

RESULTS: Over 14 Months, we administered 531 surveys; 468 respondents answered at least three of the four questions (response rate 88 %) at nine CTSI/CERP community conferences/workshops. The majority of participants were female (76 %); 49 % were ages 50 years or older; 13 % had a high school education or less; and 53 % were African American, 20 % Latino, 12 % White, 11 % Asian/Pacific Islander, and 4 % other race/ethnicity. The mean distrust score over the timeframe of CTSI/CERP workshops was 1.22 (standard deviation 1.29). The adjusted estimated mean distrust index score (± standard error) decreased from 2.19 ± 0.30 in 2012 Q2 to 1.05 ± 0.26 in 2013 Q3 ($p=0.0035$). The estimated change in the distrust index score for African Americans from 2012 Q2 (mean ± SE: 2.34 ± 0.32) to 2013 Q3 (0.82 ± 0.26) was significant ($p=0.0002$), but did not reach statistical significance for Latinos (1.56 ± 0.77 vs. 0.69 ± 0.30 , $p=0.30$), Whites (2.54 ± 0.56 vs. 2.93 ± 0.54 , $p=0.62$), and Asians (0.90 ± 0.62 vs. 1.23 ± 0.37 , $p=0.65$).

CONCLUSIONS: The multivariable analyses suggest that CTSI/CERP efforts to increase community engagement in research have been associated with a decrease in distrust in health research, especially among African American participants. These findings are observational and represent ecologic associations; thus our results may be biased by secular trends. Additional qualitative work is needed to better understand reasons for change in levels of distrust over time in these diverse communities as a result of the CTSI/CERP.

CAN THYROID BREAK YOUR HEART? ROLE OF THYROID IN TAKOTSUBO CARDIOMYOPATHY: A SINGLE CENTER RETROSPECTIVE STUDY Sourabh Aggarwal; Vishal Gupta. Western Michigan University School of Medicine, Kalamazoo, MI. (*Tracking ID #1940273*)

BACKGROUND: Takotsubo cardiomyopathy (TC) is a transient systolic dysfunction of the apical and/or mid segments of the left ventricle that mimics myocardial infarction (MI) but in the absence of obstructive coronary artery disease. The exact etiology of TC is unclear. Few isolated case reports have described association of TC with hyperthyroid state. The exact association of thyroid status and TC has never been studied so far.

METHODS: This was a single center retrospective study. All the patients diagnosed with TC between January 2006 and December 2012 at our hospital were identified retrospectively. Mayo's revised criteria for TC was used to confirm the diagnosis. Baseline parameters including demographic profile, cardiac markers, thyroid studies, angiographic and echocardiographic findings were extracted and analysed using SPSSv19.0.

RESULTS: Seventy eight patient were identified as diagnosed with TC with 72 females (92.3 %) and six males (7.6 %) with mean age of 66.33 ± 13.37 years (range 23–91). Stressful event precipitating TC was identified only in 19 patients (24.36 %) at the time of admission. Twenty seven patients (34.61 %) had history of hypothyroidism and 25 patients (31.05 %) were on levothyroxine replacement. Thyroid profile was available for 44 patients at the time of admission and five patients (11.36 %) were found to be in a hyperthyroid state based on low TSH and/or high freeT4. During a mean follow up of 2.8 ± 1.5 years, five patients (5.13 %) had episodes of recurrence. Mean length of stay (mLOS) was 4.4 ± 3.9 days (Median 3 days, Range 1–23 days). Both TSH level and ejection fraction had significant independent negative correlation with mLOS ($p<0.05$).

CONCLUSIONS: Thyroid status/thyroid hormone replacement may have a significant role in the pathogenesis of TC. In this first retrospective study describing the association of TC with thyroid status, precipitating stress was identifiable in only 24 % patients whereas 35 % of the patients had a history of hypothyroidism with majority on levothyroxine replacement. Additionally, TSH level had an independent negative correlation with mLOS.

CARE FRAGMENTATION AND SURVIVAL FOR PATIENTS WITH STAGE III COLON CANCER Tanvir Hussain^{1,2}; Hsien-Yen Chang²; Christine M. Veenstra³; Craig E. Pollack^{1,2}. ¹Johns Hopkins University School of Medicine, Baltimore, MD; ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ³University of Michigan Health Systems, Ann Arbor, MI. (*Tracking ID #1939909*)

BACKGROUND: Cancer care can be complex and fragmented, spanning many settings and providers. Though the Institute of Medicine cites fragmentation as a priority for improving cancer care, little is known about aspects of fragmentation that affect cancer outcomes. We examine two features which may have different implications for improving care delivery: receiving surgical and medical oncologic care from providers affiliated with different hospitals; and receiving care from a surgeon-oncologist pair who infrequently shares patients with one another. We focus on stage III colon cancer patients as guidelines recommend both surgery and chemotherapy.

METHODS: Patients with stage III colon cancer diagnosed between 2000 and 2005 were identified from SEER-Medicare data. Patients were assigned to their operative surgeon and the medical oncologist who billed for the plurality of their visits in the year following diagnosis. Surgeons and oncologists were linked to the hospital where they billed most for inpatient care. Patients were classified as experiencing "hospital fragmentation" if their surgeon and oncologist were assigned to different hospitals (versus the same hospital). We determined the number of patients each surgeon-oncologist pair shared; patients were classified as having "high patient-sharing" physicians if their oncologist and surgeon shared many patients (top quartile of the shared patients distribution versus lower three). Patient-sharing has been validated as a measure of collaboration and information exchange between physicians. Our primary outcome was all cause mortality (censor date 12/31/2007). Secondary outcomes included timely receipt of chemotherapy (9 months of diagnosis) and cost of care [total claims using MEDPAR (Part A), NCH (Part B), and Outsa files] in the 12 months following diagnosis. We used Cox proportional hazard and regression models, adjusted for patient demographics, socioeconomic status, comorbidities, SEER site; surgeon's yearly procedure volume, oncologist patient panel size; and hospital characteristics (volume; NCI, for-profit, and academic status). Generalized estimating equations and robust standard errors were used to account for hierarchical data and clustering.

RESULTS: Our sample included 7443 patients. Median survival was 3.04 years. One-third ($N=2471$) received care from surgeons and oncologists associated with different hospitals. No difference in morality was associated with hospital fragmentation (adjusted HR=1.00, 95 % CI: 0.93–1.07). We observed an increased risk of death among patients whose surgeons and medical oncologists shared few patients (lower three quartiles of shared patients) compared to those whose doctors were in the top quartile (HR=1.15, 1.06–1.25). No statistical interaction between the two predictors was noted in the final model (Wald's test, $p=0.324$). Neither hospital fragmentation nor patient-sharing predicted timely receipt of chemotherapy or 12 month costs of care.

CONCLUSIONS: Receiving care from physicians associated with the same hospital did not improve survival for stage III colon cancer patients, whereas receiving care from physicians sharing many patients with another did. These results suggest that efforts to improve care fragmentation need to examine the informal relationships between physicians that may be reflected by patient-sharing. Further, cancer survival, quality, and costs may not be improved by delivery redesign which addresses fragmentation solely by consolidating options for care to one institution.

CAUSES OF SHORT-TERM HOSPITAL MEDICINE READMISSIONS AT AN ACADEMIC MEDICAL CENTER Kenton Smitherman; Brian Clay; Leslie Martin-Armstrong. UC San Diego Medical Center, San Diego, CA. (Tracking ID #1927644)

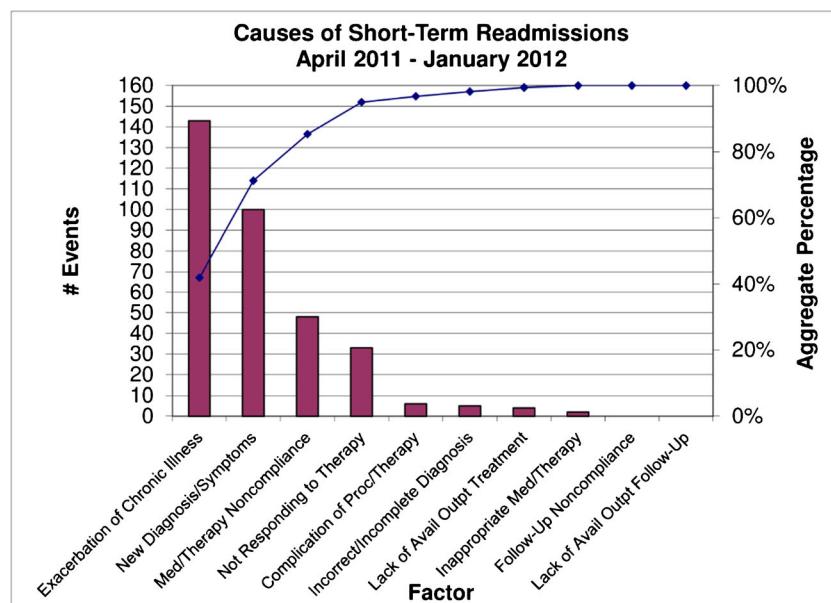

BACKGROUND: Health care continues to undergo significant changes. With the recent creation of the Hospital Readmission Reduction Program (HRRP) by the Centers for Medicare and Medicaid Services (CMS), financial penalties are being

assessed to hospitals with high 30-day readmission rates for certain patient groups. Investigating reasons for readmissions could be important in identifying possible patterns and areas for improvement. The objective of this study was to identify the primary contributing cause for each of 341 short-term readmissions (within 7 days of discharge) to ten hospital medicine services at an academic medical center over the ten-month period from 4/1/2011 through 1/31/2012.

METHODS: The UC San Diego Health System includes two hospitals with a combined capacity of 552 beds. Use of a full-spectrum inpatient electronic medical record (EMR) began on February 27, 2011 (a system-wide outpatient EMR was already in place). During the period of April 2011 through January 2012, there were 5,789 admissions to the hospital medicine services. From this total, 341 were readmissions within 7 days. These readmission cases were retrospectively reviewed by two members of the Division of Hospital Medicine to determine the primary factor causing each patient's readmission. Patient, health system, and physician factors were considered. Patient factors included: (a) exacerbation of chronic illness, (b) new/separate diagnosis, (c) noncompliance with medication or other therapy, (d) noncompliance with outpatient follow up, and (e) patient not responding to reasonable medication or other therapeutic plan. Health system factors were: (a) lack of timely available outpatient follow up appointment, and (b) inability to provide medication or other therapy in the outpatient setting or at a lower level of care. Physician factors included: (a) discharge with inappropriate medications or therapy, (b) incorrect or incomplete diagnosis (excluding cases when further workup in the outpatient setting was planned), and (c) complication of a procedure or therapy instituted during the preceding hospitalization.

RESULTS: Case review showed that most (95 %) short-term readmissions resulted from patient factors: 42 % of cases were due to exacerbations of chronic illness, 29 % were due to new or separate diagnoses, none were shown to be due to noncompliance with follow up (these readmissions were within 7 days of discharge), and 10 % were due to patients not responding to reasonable medication or other therapy. The health system factor of inability to provide medication or other therapy in the outpatient setting or at a lower level of care was deemed the primary cause of readmission in 1 % of cases. Importantly, physician factors were the primary cause of readmission in 13, or 4 %, of the cases: 2 readmissions were due to discharge with inappropriate medications or therapy, 5 readmissions were due to incorrect or incomplete diagnosis, and 6 readmissions were the result of a complication of a procedure or therapy instituted during the preceding hospitalization. Additionally, in this 341 case cohort, 16 % of the readmission cases involved patients with chronic liver disease, and 8 % of the cases involved patients who were homeless.

CONCLUSIONS: Most short-term readmissions to our hospital medicine services are due to patient factors. Health system and physician factors were identified as causes of readmissions in only 5 % of cases. Penalizing hospitals with higher readmission rates may not be a proper tool for decreasing hospital readmissions within 7 days of discharge.

CHALLENGES TO INCREASING ACCESS AND CONTINUITY IN A LARGE ACADEMIC MEDICAL CENTER IMPLEMENTING PCMH Claire Robinson¹; Molly Harrod¹; Jane Forman¹; Ann-Marie Rosland^{1,2}; Adam Tremblay^{1,2}; Eve A. Kerr^{1,2}. ¹VA Ann Arbor Health Care System, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI. (*Tracking ID #1937578*)

BACKGROUND: A core goal of the patient-centered medical home (PCMH) model is to increase timely access to primary care while maintaining patient-provider continuity. While definitions of access vary, it is often operationalized as receiving a same-day appointment with the patient's usual provider. For example, the Department of Veterans Affairs (VA) has implemented a national performance measure examining receipt of same-day appointments with the patient's usual primary care provider (PCP). Large academic primary care clinics face unique challenges in providing prompt access to a patient's usual provider, particularly because many of these clinics are staffed by providers and residents who are in the clinic only a few hours each week ('part-time providers'). We examined factors affecting efforts to increase prompt access and provider continuity in a large VA academic medical center that was in the process of implementing PCMH. Among the medical center's 78 PCPs, 59 were available in clinic half-time or less. We have previously shown that part-time providers at this medical center were less likely to meet the national access measure.

METHODS: We conducted 20 semi-structured interviews with primary care staff (physicians, residents, registered nurses, licensed practical nurses, and clerks), roughly one and a half years into PCMH implementation. We also observed more than 25 h of coaching sessions designed to help newly formed primary care teams redesign their delivery processes to improve their access and continuity measures. We coded interview transcripts and coaching observation field notes with descriptive, non-hierarchical, grounded codes that emerged from the data and developed findings via group consensus.

RESULTS: We conducted 20 semi-structured interviews with primary care staff (physicians, residents, registered nurses, licensed practical nurses, and clerks), roughly one and a half years into PCMH implementation. We also observed more than 25 h of coaching sessions designed to help newly formed primary care teams redesign their delivery processes to improve their access and continuity measures. We coded interview transcripts and coaching observation field notes with descriptive, non-hierarchical, grounded codes that emerged from the data and developed findings via group consensus.

CONCLUSIONS: The large number of part-time primary care providers and residents combined with the large volume of patients made same-day access with the patient's usual PCP challenging. Increased flexibility to schedule non face-to-face visits during part-time PCP's non-clinical duties could help improve access. However, strategies that promote a team approach to access are likely the only long-term solution if we are to improve access while continuing to support providers who choose or need to work part-time. More information is needed on patient needs and preferences for prompt access and continuity in academic environments, so these new strategies can be tailored to patient-centered goals.

CHARACTERISTICS OF PERSISTENT EMERGENCY DEPARTMENT HIGH UTILIZERS IN A LARGE PRIMARY CARE PRACTICE-BASED RESEARCH NETWORK Andrew S. Hwang¹; Shan W. Liu²; Carine Yelbi³; Jeffrey M. Ashburner³; Wei He³; Brandon Auerbach³; Steven J. Atlas³; Clemens S. Hong³. ¹Tufts University School of Medicine, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Massachusetts General Hospital, Boston, MA. (*Tracking ID #1934654*)

BACKGROUND: A small percentage of high-utilizing patients account for a disproportionate share of emergency department (ED) visits. Understanding the characteristics of persistent high-utilizers may allow for more effective design of interventions to reduce ED utilization and costs.

METHODS: We performed a cohort analysis to study ED high-utilizers among 161,707 patients receiving care in a large primary care practice-based research network (PBRN) between 2005 and 2007. We identified all PBRN patients who visited the ED ≥4 times in 2007, and divided them into 2 groups: 1) patients who also made ≥4 ED visits between 2005 and 2006 (persistent users) and 2) patients who made <4 ED visits between 2005 and 2006 (non-persistent users). We compared the following characteristics in the two groups: demographic characteristics, chronic conditions, behavioral health problems, count of electronic medication prescriptions (e-prescriptions), and past healthcare utilization (between 2005 and 2007). We used

Poisson regression models to assess the association between persistent ED high-utilization and subsequent ED visits and hospitalizations over 5 years (2008–2012) using a "change-in-estimate" strategy, where we included potential covariates (marriage status, insurance, language, chronic conditions, behavioral health problems, count of e-prescriptions, and past healthcare utilization) in the models if they altered the incidence rate ratio (RR) by >5 %.

RESULTS: Among 697 patients with ≥4 ED visits in 2007, 276 (40 %) were persistent users. Compared to non-persistent users, persistent users were significantly ($p<0.01$ for all) more likely to be unmarried (80 % vs. 70 %) and English speaking (93 % vs. 87 %), have non-commercial insurance (81 % vs. 68 %), or have a diagnosis of coronary artery disease (26 % vs. 17 %), chronic obstructive pulmonary disease (49 % vs. 38 %), congestive heart failure (50 % vs. 40 %), chronic pain (18 % vs. 10 %), depression (16 % vs. 8 %), bipolar disorder (18 % vs. 11 %), psychosis (44 % vs. 27 %), or alcohol- (34 % vs. 17 %) or drug-related problems (37 % vs. 21 %). Persistent users also received a higher total number of e-prescriptions over 3 years (53 vs. 40) and were more likely to be e-prescribed narcotics (88 % vs. 77 %), benzodiazepines (83 % vs. 69 %), anti-psychotics (55 % vs. 36 %), and medications for depression/anxiety (64 % vs. 50 %) or smoking cessation (24 % vs. 16 %). Compared to non-persistent users, persistent users had higher rates of missed primary care appointments (19 % vs. 14 %), and higher unadjusted rates of acute care utilization (2,685 vs. 1,134 ED visits/1,000 patients/year and 1,822 vs. 934 admissions/1,000 patients/year) in the prior 3 years (2005–2007). Compared to non-persistent users, persistent users also had higher unadjusted rates of acute care utilization (2,030 vs. 1,483 ED visits/1,000 patients/year and 892 vs. 440 admissions/1,000 patients/year) over the subsequent 5 years. Adjusting for prior ED visits and hospitalizations, compared to non-persistent users, persistent users had a higher rate of subsequent hospitalization (adjusted RR 1.33 [1.08–1.65]), but not a higher rate of subsequent ED visits (adjusted RR 1.31 [0.93–1.84]). Including all covariates in the models changed the overall effects by less than 4 % for both outcomes without changing effect direction or significance.

CONCLUSIONS: Compared to non-persistent ED high-utilizing patients, persistent ED high-utilizing patients are more medically and psychosocially complex and have a higher risk of future hospitalization. Persistent ED high-utilizers represent an important target for intervention to improve quality and reduce costs. Such efforts will likely require intensive, multidisciplinary, care management approaches.

CHARACTERIZATION AND LACK OF PLANNING FOR ADVANCED LIFE EVENTS AMONG OLDER ADULTS Lee Lindquist¹; Priya Sunkara¹; Vanessa Ramirez-Zohfeld¹; Chris Forcucci²; Megan Huisingh-Scheetz³; Kenzie A. Cameron¹. ¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Aging and In-Home Services, Fort Wayne, IN; ³University of Chicago, Chicago, IL. (*Tracking ID #1939204*)

BACKGROUND: Despite older adults' wish to remain independent in their own homes, critical health and life events occur that impede their ability to do so. A lack of information exists on what these advanced life events (ALE) entail and the advanced planning older adults perceive is necessary.

METHODS: We conducted focus groups with older adults living in community and independent living facilities in rural, suburban, and urban locales. Subjects were asked to discuss their future living plans and events/experiences that might impact their ability to remain in their own home. Focus group questions also elicited if subjects had planned for, discussed with others (e.g. spouse, offspring), or acted on these plans if one of these advanced life events occurred to them. Content analysis and constant comparative analysis was used to analyze the results.

RESULTS: Across all sites, 68 older adults participated in the focus groups with a mean age of 73.9 years (SD=6.53); 50 (73.5 %) were female. Analysis revealed older adults perceived several major advanced life events impacted a senior's ability to remain in their own home: 1) Hospitalization or Serious Illness, 2) Functional Loss 3) Cognitive loss, 4) Spousal death. Subjects voiced experiences with each of these events in multiple forms (e.g. self, spouse, friend, relative). However, very few perceived these events would occur to them, "I've decided I'm not going to get Alzheimer's!" Planning for these events were almost non-existent as many older adult subjects felt that they were too sick or too healthy to look forward. "I'm on borrowed time. So I'm not going to worry about where I'm going to go for my old age because I don't think I'm going to have one." "The new 70 is the old 58!" A number of seniors also felt that offspring would handle it for them although, many subjects stated that they had not discussed current or future needs with their offspring. While many subjects voiced that they had completed end-of-life documentation, including powers of attorney, living wills, obituary/funeral requests, there was

a lack of advanced planning for life events that have a high likelihood of occurring to seniors.

CONCLUSIONS: Helping seniors to create plans for Advanced Life Events (e.g. hospitalization, cognitive loss, functional loss) is important as it provides seniors a voice in their future while including key stakeholders (e.g. offspring, spouse). It is well known that these ALEs have a high propensity for occurring with age. Ongoing research will create and test a planning tool that will assist older adults in being prepared for their needs during these events. By planning for—instead of reacting to—ALEs, older adults may be able to remain in their own homes safer and longer.

CHILDREN: A BARRIER TO MATERNAL HEALTH CARE UTILIZATION?

Christina Pham²; Johannes R. Kratz¹; Danny McCormick². ¹Massachusetts General Hospital, Cambridge, MA; ²Harvard Medical School/Cambridge Health Alliance, Cambridge, MA. (*Tracking ID #1936573*)

BACKGROUND: Prior studies have demonstrated that women with children are at higher risk for obesity, metabolic syndrome, cardiovascular disease, depression, and all-cause mortality than women without children. No prior studies have examined the impact of having a young child on a mother's utilization of primary, specialty and preventive care that could mediate these disparities.

METHODS: We analyzed cumulative data from 5 years (2008–2012) of the National Health Interview Survey (NHIS). The NHIS is a representative nationwide sample of households conducted annually by the Centers for Disease Control and Prevention (CDC) through face-to-face in home interviews. The study sample included women age 60 or younger who answered the Family, Person, and Sample Adult surveys (57,746). The NHIS collects data on the number of children under the age of 18 at home, age, income, race/ethnicity, education level, employment status, and health insurance. The primary outcome of this study was having a visit to a primary care

physician in the preceding year. Secondary outcomes included visits to a medical specialist or Ob/Gyn in the past year as well as basic health preventative care such as blood pressure checks, cholesterol checks, tetanus shots, mammograms, and Pap smears in the past year. The primary predictor variable was having one or more children under the age of 18 in the home. A total of 27,918 (48.4 %) patients had children under the age of 18; 29,828 (51.6 %) did not. We used multivariable logistic regression models to test associations between predictor and outcome variables while controlling for age, income, race/ethnicity, education level, employment status, and health insurance.

RESULTS: The mean age of the patients was 36.3 and 42.3 for patients with and without children. When adjusted for age, income, race, educational level, employment status, and health insurance, patients who had children under the age of 18 had a 12 % lower odds of having a PCP visit in the preceding year (OR=0.88 [95 % CI, 0.85–0.92]; $P<0.001$) and a 27 % lower odds of having seen a medical specialist (OR=0.73 [95 % CI, 0.70–0.76]; $P<0.001$) in the past year. Patients with children under the age of 18 also had a lower odds of receiving basic health screening such as blood pressure checks (OR=0.90 [95 % CI, 0.83–0.97]; $P=0.009$), cholesterol checks (OR=0.91 [95 % CI, 0.86–0.96]; $P=0.003$), tetanus shots (OR=0.94 [95 % CI, 0.90–0.97]; $P=0.001$), and mammograms (OR=0.85 [95 % CI, 0.79–0.92]; $P<0.001$). In contrast, women with children had a higher odds of visiting an Ob/Gyn (OR=1.22 [95 % CI, 1.18–1.27]; $P<0.001$) and of having received a Pap smear (OR=1.29 [95 % CI, 1.22–1.37]; $P<0.001$) in the past year. Decreased health care utilization was not a function of cost of care: patients with children had a lower odds of reporting needing medical care but not receiving it because of cost (OR=0.72 [95 % CI, 0.68–0.77]; $P<0.001$).

CONCLUSIONS: Women with children younger than 18 years old are less likely to engage in their own primary care and receive important preventive care than women without young children. Current health care delivery system models may not be optimally structured to meet the needs of women with children.

CHOOSING WISELY: DO PHYSICIANS AND PATIENTS AGREE ON WHAT CONSTITUTES HIGH-VALUE MEDICAL CARE? Ana Sofia Warner¹; Neel Shah^{1,3}; Abraham Nick Morse¹; Eliyahu Lehmann²; Rie Maurer²; Zoe Moyer²; Lisa Lehmann^{1,2}. ¹Harvard Medical School, Boston, MA; ²Brigham and Women's Hospital, Boston, MA; ³Beth Israel Deaconess Medical Center, Boston, MA. (*Tracking ID #1938226*)

BACKGROUND: Healthcare delivery systems focus on the concept of value delivery as a way of optimizing patient experience and outcomes while containing

costs. Value, patient health outcomes per dollar spent, is a concept that providers, patients and policymakers embrace. Although the Choosing Wisely campaign targets physicians and patients to promote high-value care, there is little data on whether there is concordance between physicians' and patients' interpretation of value, particularly for care that has been identified as wasteful, such as unindicated imaging and antibiotic use.

METHODS: To assess physicians' and patients' perceptions of the value of care we conducted a cross-sectional survey of 201 primary care patients and 150 primary care physicians at three academic medical centers. The first vignette described a patient

with symptoms of a tension headache who is concerned about a brain tumor, but initially denied imaging. The second vignette described a patient with 3 days of symptoms consistent with a viral infection who requests and is denied antibiotics. Respondents rated the care provided in each vignette on a 5-point Likert scale (see Table 1). Descriptive statistics were used to describe frequencies. Chi-square and Fisher's exact tests were used to compare proportions between patients and physicians. Univariate regression analysis was used to assess predictors of patients' rating care as high value. Multivariable regression analysis is ongoing.

RESULTS: The response rate was 63 % (201/319) for patients and 53 % (150/283) for physicians. Among patients, 37 % were men, 63 % were white. Physicians more often reported that imaging for a tension headache represented low-value care than patients (77 % vs. 38 %, $p<0.001$), and more often reported that denying antibiotics for a viral infection represented high-value care (95 %, vs. 66 %, $p<0.001$). Patients improved their rating of care after they were told about the potential harms of radiation, and after receiving information about potential side effects and reasons for

not providing antibiotics or imaging (15 % increase in positive ratings for both scenarios). Patients who were concerned about receiving too few tests, treatments and medications were less likely to give a high rating to Part 1 of the headache vignette (OR 0.42 (0.23–0.78) $p<0.006$), while patients who rated their own health higher were more likely to rate it favorably ($p<0.01$). Patients who had seen their physicians more often were more likely to rate Part 1 of the URI vignette highly ($p<0.03$). More educated and white patients were more likely to rate Part 1 of both vignettes highly ($p<0.01$).

CONCLUSIONS: There is significant disagreement between physicians' and patients' perceptions of the value of care. Patients are more likely to favorably rate care withholding antibiotics than care withholding imaging. Patients are likely to improve their rating of care if they are informed about potential side effects, reasons for not providing antibiotics or imaging, or national guidelines consistent with their doctor's care. Addressing these topics in clinical settings will be critical to our ability to contain healthcare costs and deliver high value care.

CLASSIFICATION OF THEMES HIGHLIGHTS BOTH VARIABILITY AND CONSISTENCY IN PHYSICIAN APPROACHES TO PROFESSIONAL DILEMMAS

Elizabeth C. Bernabeo¹; Shiphra Ginsburg²; Eric Holmboe¹. ¹American Board of Internal Medicine, Philadelphia, PA; ²University of Toronto, Toronto, ON, Canada. (Tracking ID #1940171)

BACKGROUND: Professionalism is grounded in a dynamic system comprised of elements at the individual, social, and societal level. In this view, a physician's professional behavior is dependent on their personal characteristics, yet also influenced by situational and contextual phenomena arising during learning and practice. Identifying and reflecting on situational context may be difficult for physicians, particularly for physicians in real time professional dilemmas or for whom certain responses have become a personal style or habit.

METHODS: As part of an initiative to develop a self-directed approach to assessment of professionalism, we asked a random sample of general internists and specialists in outpatient and inpatient settings ($N=366$) to complete an anonymous web-based survey addressing physician approaches to typical professional challenges. The survey prompted physicians to rate the likelihood of their responding in stated ways, and to rate the importance of a set of contextual factors in their decision making. Physicians also responded to open ended questions prompting alternative responses, additional factors that guided those responses, and what kind of new learning or impact the activity had on themselves personally.

RESULTS: The overall response rate was 132/366 (36.1 %). Qualitative analysis of the open ended comments revealed several themes around which physicians approach professional dilemmas. Physicians were guided by issues of patient welfare (e.g. "I tend to come down on the side of what is best for the patient"), how much they like the patient (e.g. "Decisions are influenced by the level of the relationship with the patient"), policy, ethics, or legal issues (e.g. "I am worried about litigation"), and principles, values or rules (e.g. "I follow my own rules"). We further identified several personal styles or habits of physicians in responding to professional

dilemmas: lenient (e.g. "I am too eager to please"), avoidant (e.g. "I have a great concern about the hassle factor"), and inconsistent (e.g. "I am not consistent with certain patients or behaviors").

CONCLUSIONS: Physicians were able to reflect on personal approaches and factors listed on the survey, as well as those that were not. The classification of themes that guide physician decisions in professional dilemmas is important, and suggests that despite variability in responses, physicians think about professionalism in systematic and complex ways. Helping physicians explore and identify with their personal reactions to professional dilemmas in a deliberate way can help promote mindfulness and renew interest and commitment to professionalism in practice. Self awareness and reflection are infrequent in medical practice, yet may be powerful agents of change for physicians.

CLASSIFYING PATIENT STATEMENTS ABOUT UNCONTROLLED PAIN IN PRIMARY CARE

Stephen G. Henry¹; Richard L. Kravitz¹; Robert A. Bell².

¹University of California Davis, Sacramento, CA; ²University of California Davis, Davis, CA. (Tracking ID #1938853)

BACKGROUND: Physicians frequently cite patient requests for opioids as one reason that visits involving patients on opioids are often frustrating. Past research in this area has focused on "difficult" visits or patients in specialty pain clinics. Little is known about how patients on opioids actually discuss uncontrolled pain during routine primary care visits.

METHODS: Data were derived by coding transcripts of routine primary care visits that were recorded as part of a clinical trial that compared two interventions designed to facilitate patient discussion of depression symptoms. First, we read transcripts to identify patients on chronic opioids (i.e. taking at least 1 dose/day for >90 days). Second, we iteratively reviewed transcripts to develop and apply a coding system to identify strategies patients used to express poorly controlled pain. Our final coding system was adapted from Street's system for coding patient participation and comprised four types of patient statements: *concerns* (statements expressing negative

emotions about pain), *questions, requests for action* (e.g. referral), and *assertive statements*.

RESULTS: We identified 26 eligible transcripts that included patients on opioids for chronic pain. Patient concerns were the most common statement type ($n=84$) followed by questions ($n=32$), requests for action ($n=22$) and assertive statements ($n=16$). Approximately 28 % ($n=43$) of statements related to pain and suffering in general, 20 % ($n=31$) pertained to pain-related functional impairment, 29 % ($n=44$) were about non-opioid pain treatments, 19 % ($n=29$) related to opioids, and 5 % ($n=7$) concerned the underlying pain diagnosis. One patient requested a change from methadone to oxycodone after the physician suggested this change. All other requests for opioid prescriptions involved refills of patients' existing opioid prescriptions. No direct requests for higher opioid doses were observed.

CONCLUSIONS: Patient were more likely to mention uncontrolled pain indirectly (i.e., through statements of concern and/or questions) rather than through direct requests for action or assertive statements. Statements about opioids comprised a minority of patient statements about uncontrolled pain. Contrary to conventional wisdom, direct patient requests for higher opioid doses appear uncommon in routine primary care visits involving patients on opioids for chronic pain.

CLINICAL CHARACTERISTICS OF PATIENTS ADMITTED FOR ACUTE EXACERBATION OF COPD THAT PREDICT SHORTER LENGTH OF STAY

Matthew Cerasale¹; Khalil Mroue²; Juan Cesar Fernandez Castillo¹; Jennifer Swiderek³; David Paje¹. ¹Henry Ford Hospital, Detroit, MI; ²Wayne State University School of Medicine, Detroit, MI; ³Henry Ford Hospital, Detroit, MI. (Tracking ID #1940337)

BACKGROUND: Chronic Obstructive Pulmonary Disease (COPD) exacerbation is a common clinical condition that may lead to frequent hospitalization. However, identifying which patients would be appropriate for a short stay in an observation unit rather than an inpatient admission has not been well established. The aim of this study was to determine which patient characteristics and clinical findings are associated

with hospitalizations of <48 h, and thus can be used to guide referral to the observation unit.

METHODS: The study is based on a retrospective review of the medical records of patients who were primarily hospitalized for acute exacerbation of COPD to an 805-bed teaching hospital. Patients were excluded if they were admitted directly to the intensive care unit. Demographic data, baseline history and clinical findings in the emergency department and upon arrival to a hospital unit were abstracted. The occurrence of all-cause death, readmission and revisit to the emergency department within 30 days were also recorded. The clinical characteristics of patients who stayed <48 h were compared to those who stayed longer using independent T-tests for continuous variables and Chi-squared test for categorical variables.

RESULTS: The medical records of 181 patients who were primarily hospitalized for acute exacerbation of COPD between 2009 and 2013 were reviewed. There were 68 (38 %) patients who stayed <48 h (mean length of stay [LOS], 1.63 ± 0.62 days) and 113 (62 %) patients who stayed longer (mean LOS, 3.82 ± 1.99 days). Both groups were similar in terms of age, sex, and racial distribution. They were also similar with regards to smoking status, prior use of inhaled steroids and anticholinergics, intubation within the past year, and hospital admission in the past year. Compared to patients who stayed longer, patients who stayed <48 h had faster initial respiratory rate in the emergency department (23.82 ± 6.05 /min vs. 21.42 ± 4.00 /min, $p=0.002$) and they had higher initial hemoglobin (13.26 ± 1.44 g/dL vs. 12.53 ± 1.89 g/dL, $p=0.007$). The rest of the initial clinical findings in the emergency department and upon admission were similar in both groups. The rates of 30-day outcomes were also comparable: revisit to the emergency department within 30 days (22 % vs. 15 %, $p=0.3197$), inpatient readmission (18 % vs. 14 %, $p=0.6801$) and death from all causes (0 % vs. 2 %, $p=0.7083$).

CONCLUSIONS: A significant proportion of patients who are admitted for acute exacerbations of COPD stay less than 48 h. There are no clinically significant differences in baseline characteristics and in initial clinical findings between patients who stay longer and those who stay less than 48 h. Clinical outcomes were also similar in both groups.

Table 1. Baseline Characteristics of Patients Hospitalized for Acute Exacerbation of Chronic Obstructive Pulmonary Disease

Baseline Characteristic	Length of Stay		p-value
	< 48 hours N=68	≥ 48 hours N=113	
Age (mean ± SD)	60.38±12.49	63.70±13.36	0.1

CLINICAL EXCELLENCE IN HOSPITAL MEDICINE: INSIGHT GLEANED THROUGH OBSERVATION Susrutha Kotwal; Eric Howell; Haruka Torok; Regina Landis; Scott Wright. Johns Hopkins Bayview Medical Center, Baltimore, MD. (Tracking ID #1925957)

BACKGROUND: As of July 2010, there were more than 30,000 hospitalists in the United States. The quality of care rendered by hospitalists is not uniform. Although patient satisfaction metrics like Press Ganey attempt to measure service excellence, no empiric research has been performed to characterize or define clinical excellence in hospital medicine.

METHODS: The Chiefs of Hospital Medicine at five different hospitals were emailed and asked to identify the “clinically excellent” hospitalists within their groups. The named hospitalists were invited to participate in the study; those agreeable would be shadowed during routine clinical care of patients. A data extraction sheet was developed and pilot tested to focus the observer’s attention on elements believed to be associated with clinical excellence. Detailed field notes, both quantitative and qualitative, were collected during the observation.

RESULTS: A total of 26 hospitalists were shadowed as they took care of patients. The average age of the physicians was 38 years and their average experience in hospital medicine was 6 years. Each hospitalist was observed for an average of 5 h and they were observed with a mean of seven patients (total number of patient encounters observed = 197). On average, the physicians spent 11 min with each patient; patients were examined for a mean of 100 s. In terms of balance of dialogue, these respected providers spoke on average 71 % of the time during the discourse. The frequency of certain select desirable behaviors observed were as follows: starting encounters with an “open ended” question (76 %); integrating non-medical conversation to connect with patient (30 %); displaying empathy during the encounters (27 %). Each encounter was given a global rating and 14 % were judged to be “clinically excellent”. Several reasons that encounters were judged not to be “clinically excellent” were the lack of non-medical conversation used to connect with patients (70 % of the encounters), doctor neglected to wash hands prior to entering room (24 % of the encounters), doctor did not uncover/disrobe the body part being examined (39 %), and failing to ask permission prior to examining the patient (36 %).

CONCLUSIONS: This study represents a first step in trying to characterize clinical excellence in Hospital Medicine, using both qualitative and quantitative data. Because hospitalists spend only a small amount of time with patients, relative to the time spent in indirect patient care, it is imperative that we make the most of this caring time and strive for clinical excellence consistently during every encounter.

CLINICAL IMPACT OF MEDICAL ASSISTANT HEALTH COACHING IN LOW-INCOME PATIENTS WITH UNCONTROLLED DIABETES, HYPERTENSION, AND HYPERLIPIDEMIA: A RANDOMIZED CONTROLLED TRIAL David Thom; Rachel Willard-Grace; Danielle Hessler; Denise DeVore; Camille Prado; Thomas Bodenheimer; Ellen Chen. University of California, San Francisco, San Francisco, CA. (*Tracking ID #1925738*)

BACKGROUND: Medical assistants, part of one of the fastest growing allied health professions, are more likely than clinicians to be culturally and linguistically concordant with patients. Medical assistants trained in health coaching could provide an important resource as members of the primary care team. Previous studies of medical assistant health coaching programs found positive trends in clinical outcomes such as hemoglobin A1c but were not designed as randomized trials, lacked power to find statistically significant differences, and focused on a single condition such as diabetes or hypertension. We conducted a randomized controlled trial to test the effectiveness of clinic-based medical assistant health coaching versus usual care to improve clinical outcomes among low-income patients with uncontrolled type 2 diabetes, hypertension, and/or hyperlipidemia over 12 months.

METHODS: The Health Coaching in Primary Care enrolled low-income patients with uncontrolled diabetes (hemoglobin A1C (HbA1C) > 8.0 %), hyperlipidemia (LDL > 130 mg/dL or > 100 mg/dL if diabetic), and/or hypertension (SBP > 140 mmHg) from two safety-net clinics. Patients were randomized to receive usual care or health coaching from a medical assistant who completed health coach training. The primary outcome was a composite measure of being at goal (defined as HbA1c < 8.0 %; LDL < 130 mg/dL or < 100 mg/dL if diabetic; and SBP < 140 mmHg) for at least one of the conditions uncontrolled at enrollment. Secondary outcomes were meeting all possible goals and meeting each goal separately.

RESULTS: Of 654 patients determined to be eligible, 441 (67 %) were enrolled; approximately three-quarters from one clinic. Clinical outcome measures at 12 months were available for 94 % (132/144) of patients enrolled with uncontrolled diabetes, 95 % (156/165) of patients enrolled with uncontrolled hypertension, and 83 % (169/203) for patients enrolled with uncontrolled hyperlipidemia. There were no significant differences in participant characteristics by study arm (Table 1). Participants in the health coaching arm were more likely than participants in the usual care arm to achieve both the primary composite measure of one of their clinical goals and the secondary composite measure of reaching all of their clinical goals (Table 2). Almost twice the number of participants in the health coaching arm achieved the goal of HbA1c ≤ 8.0 %. At the largest study site, participants in the health coaching arm were more likely to achieve the specific LDL cholesterol goal compared to usual care (41.8 % vs. 25.4 %, difference 16.4 %, CI 1 %–32 %). There was no significant difference in the proportion of patients who met the treatment goal for hypertension.

CONCLUSIONS: Medical assistants serving as in-clinic health coaches can improve glycemic and cardiovascular health outcomes over usual care for low-income patients with uncontrolled diabetes, hypertension and/or hyperlipidemia

Table 1. Participant characteristics (% or mean (sd))

	Usual care arm (n=217)	Health coaching arm (n=224)

CMS PAYMENT REFORM AND THE INCIDENCE OF HOSPITAL-ACQUIRED PULMONARY EMBOLISM OR DEEP VEIN THROMBOSIS Risha Gidwani^{1,2}; Jay Bhattacharya³. ¹Veterans Health Administration, Menlo Park, CA; ²Stanford University, Stanford, CA; ³Stanford University, Stanford, CA. (*Tracking ID #1938121*)

BACKGROUND: The Centers for Medicare & Medicaid Services (CMS) has historically provided larger reimbursement to hospitals for inpatient stays in which a patient complication developed post-admission (a hospital-acquired condition). This manner of reimbursement financially rewarded hospitals that may have provided poor-quality care to their patients. In October 2008, CMS stopped reimbursing hospitals for the marginal cost of treating certain preventable hospital-acquired conditions. We evaluated whether CMS’s refusal to pay for hospital-acquired pulmonary embolism (PE) or deep vein thrombosis (DVT) resulted in a lower incidence of these conditions.

METHODS: This analysis employed difference-in-difference regression modeling. Difference-in-difference modeling is a quasi-experimental approach used when it is infeasible to conduct a randomized controlled trial, and when there is one group that is exposed to the intervention, another group that is unexposed to the intervention, and a single start date to the intervention. Comparing pre-post data in the exposed group to pre-post data in the unexposed group serves to remove biases that may be due to systematic differences across the unexposed and exposed groups and well as biases that may be due to larger trends in the environment. In this analysis, the intervention is CMS payment reform, the exposed group is Medicare patients receiving hip or knee surgery, the unexposed group is non-Medicare patients receiving hip or knee surgery, and the outcome of interest is the incidence proportion of PE or DVT. We limited the cohort to Medicare patients aged 65–69 and non-Medicare patients aged 60–64 to minimize the impact of age on developing PE or DVT. A hierarchical regression model was used to account for correlation between discharges within a single hospital. The model was populated using 2007–2009 data from the Nationwide Inpatient Sample, an all-payer database of inpatient discharges in the United States.

RESULTS: There were 136,634 encounters for hip or knee replacement surgery from 2007 to 2009 in patients aged 60–69. At baseline, PE/DVT occurred in 0.81 % of all hip or

knee replacement surgeries for Medicare patients aged 65–69. After adjusting for race, sex, hospital region, teaching hospital status, elective admission, rural hospital status, and median household income quartile for patient zip code, the CMS policy change was associated with a 32 % reduction, or a 0.26 percentage point reduction, in the incidence proportion of hip or knee encounters with PE or DVT. The incidence of PE or DVT in these orthopedic encounters increased from the pre-intervention to the post-intervention period for non-Medicare patients aged 60–64, while it declined in that same period for Medicare patients aged 65–69. Results were robust to changes in model specification.

CONCLUSIONS: As the U.S. healthcare system increasingly moves from fee-for-service to fee-for-value reimbursement, it becomes important to evaluate whether fee-for-value-based reimbursement has a desired effect. Our administrative-data based analysis of CMS hospital-payment reform indicates payment modification had the desired effect of reducing hospital-acquired PE or DVT amongst patients with hip or knee replacement surgeries. After controlling for other variables, the policy change was independently associated with a 32 % reduction in the incidence of hospital-acquired PE or DVT. While regression models indicate the 0.26 percentage point reduction was statistically significant, it remains the purview of policy makers and clinicians to decide whether a reduction in the incidence of these conditions from 0.81 % to 0.55 % is clinically significant. To our knowledge, this represents the first analysis of the effect of CMS payment reform on the incidence of hospital-acquired pulmonary embolism or deep vein thrombosis.

COGNITIVE REFLECTION AND ANTIBIOTIC PRESCRIBING FOR ACUTE RESPIRATORY INFECTIONS Dwan Pineros¹; Jason N. Doctor⁶; Mark W. Friedberg⁵; Daniella Meeker⁴; Yelena Kleynner³; Jeffrey A. Linder^{1,2}. ¹Brigham and Women's Hospital, Boston, MA; ²Harvard Medical School, Boston, MA; ³Partners HealthCare System, Boston, MA; ⁴RAND, Santa Monica, CA; ⁵RAND, Boston, MA; ⁶University of Southern California, Los Angeles, CA. (Tracking ID #1938790)

BACKGROUND: Clinicians frequently prescribe inappropriate antibiotics for acute respiratory infections (ARIs). One contributor to inappropriate antibiotic prescribing may be a tendency toward quick, automatic thinking by clinicians.

METHODS: The Cognitive Reflection Test (CRT) has three questions with intuitive but incorrect answers that respondents tend to reach if they do not consider the question carefully (i.e., incorrect answers that quick, automatic thinking produces). The CRT is scored from 0 to 3, representing the number of correct answers. We administered the CRT to 139 primary care clinicians in June 2013. From billing data and the electronic health record between June 2012 and June 2013, we calculated clinician-level antibiotic prescribing rates for ARIs in 3 categories: all ARIs, antibiotic-appropriate ARIs (e.g., pneumonia, streptococcal pharyngitis, or sinusitis), and non-antibiotic-appropriate ARIs (e.g., colds or acute bronchitis). We used ANOVA to compare CRT scores with antibiotic prescribing rates.

RESULTS: Thirty-three clinicians (24 %) scored 0 points on the CRT; 27 (19 %) scored 1; 45 (32 %) scored 2; and 34 (24 %) scored 3. Antibiotic prescribing rates were 28 % for all ARIs, 50 % for antibiotic-appropriate ARIs, and 17 % for non-antibiotic-appropriate ARIs. For all ARIs, the antibiotic prescribing rates for CRT scores of 0, 1, 2, and 3 were 33 %, 25 %, 26 %, and 29 %, respectively ($p=0.23$). For antibiotic-appropriate ARIs, the antibiotic prescribing rates for CRT scores of 0, 1, 2, and 3 were 51 %, 50 %, 50 %, and 50 %, respectively ($p=0.99$). For non-antibiotic-appropriate diagnoses, the antibiotic prescribing rates for CRT scores of 0, 1, 2, and 3 were 23 %, 14 %, 14 %, and 17 % ($p=0.01$).

CONCLUSIONS: Clinicians who exhibit less reflective thinking may have higher antibiotic prescribing rates for non-antibiotic-appropriate diagnoses, compared to those who are more likely to think reflectively. It is possible that differences in clinicians' cognitive reflection could contribute to other variations in care.

COLORECTAL CANCER SCREENING RATES 5 YEARS AFTER SWITCHING TO A HIGH-DEDUCTIBLE HEALTH PLAN, OVERALL AND AMONG LOWER-INCOME MEMBERS James F. Wharam¹; Bruce E. Landon²; Robert LeCates¹; Fang Zhang¹; Steve Soumerai¹; Dennis Ross-Degnan¹. ¹Harvard Medical School, Boston, MA; ²Harvard Medical School, Boston, MA. (Tracking ID #1940079)

BACKGROUND: The ACA is expected to cause a "seismic shift" in high-deductible health plan (HDHP) enrollment. Colorectal cancer (CRC) screening improves mortality but the increasing prevalence of HDHPs could reduce screening rates, especially among the poor. To protect against this, the ACA requires that health insurers cover CRC screening with no out-of-pocket costs. We studied HDHPs at a large national insurer that similarly has provided generous coverage of CRC screening tests over the last 8 years. No published studies have examined long-term CRC screening patterns after transition to HDHPs or long-term effects on the poor.

METHODS: We studied administrative claims of 28,877 HDHP members age 50–64 insured through a large national insurer between 2004 and 2011. We analyzed screening rates for 1 year before and up to 5 years after their employers mandated a switch from

traditional plans to HDHPs, compared with rates among 57,748 contemporaneous propensity score matched controls whose employers chose to remain in traditional plans. Our measure was screening with any of FOBT, flexible sigmoidoscopy, double-contrast barium enema, or colonoscopy. We considered members who received these tests screened for the next 1, 5, 10, and 10 years, respectively. We subtracted monthly screening rates of the control group from those of the HDHP group to generate a before-after difference trend, then used Joinpoint analysis to determine whether there was a statistically significant inflection point after the HDHP transition. We stratified plots and analyses by geocoded poverty status and fit a linear trend line to the baseline difference trend to generate a predicted 5-year screening rate. We fit a second-order polynomial trend line to the follow-up rates to estimate an observed 5-year screening rate.

RESULTS: CRC screening rates in the overall HDHP group relative to the control group trended down beginning in the fourth month of the first follow-up year, an estimated -0.176% per month trend change ($p<0.0001$). Both lower- and higher-income HDHP members followed a similar pattern (Figures 1 and 2). HDHP members from lower-income neighborhoods experienced an estimated 2.9 % absolute decrease in CRC screening rates after 5 years (Figure 1), while members from higher-income neighborhoods experienced an estimated 4.3 % absolute reduction (Figure 2).

CONCLUSIONS: HDHPs were associated with reduced CRC screening over 5 years, but the reduction was not greater among members from lower-income neighborhoods. Fully covering CRC screening under HDHPs might protect lower-income members to some degree from substantial reductions in screening. However, health plans and policymakers should consider strategies to broadly promote CRC screening among HDHP members.

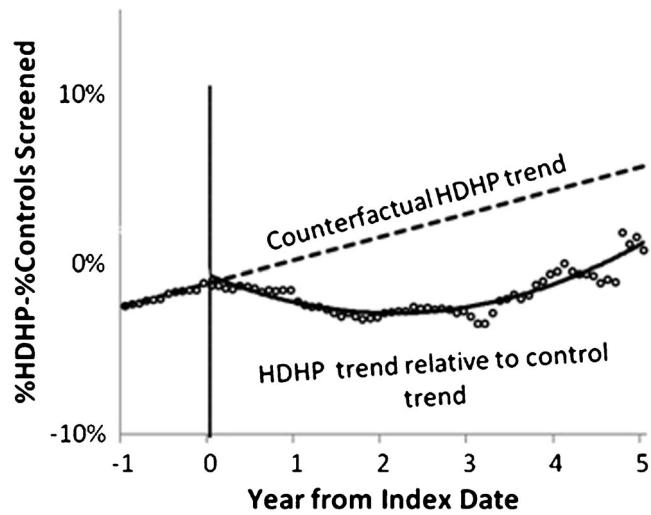

Figure 1. Difference in monthly colorectal cancer screening status between higher-income high-deductible and traditional plan members, showing counterfactual trend predicted by the baseline trend and the fitted follow-up trend.

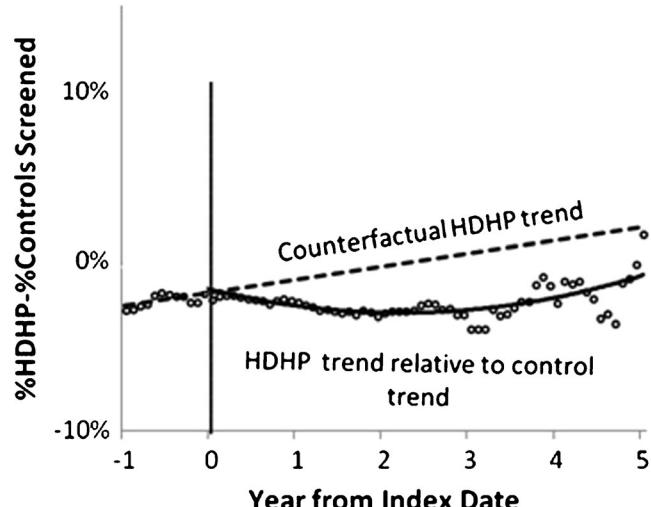

Figure 2. Difference in monthly colorectal cancer screening status between lower-income high-deductible and traditional plan members, showing counterfactual trend predicted by the baseline trend and the fitted follow-up trend.

COMMERCIAL WEIGHT LOSS PROGRAMS - WHICH ONES WORK? A SYSTEMATIC REVIEW Ruchi Srivastava¹; Kimberly Gudzune¹; Zoobia Chaudhry¹; Ambereen K. Mehta¹; David Jacobs². ¹Johns Hopkins, Baltimore, MD; ²University of Maryland, Baltimore, MD. (*Tracking ID #1935829*)

BACKGROUND: Commercial weight loss programs are popular among overweight adults, yet a 2005 review found little evidence to support their effectiveness. New studies have since tested these programs. We aimed to determine the weight loss benefits among popular commercial weight loss programs.

METHODS: We selected five programs based on expert recommendations and Internet popularity. We searched MEDLINE from 1/2002 to 6/2013. We included randomized controlled trials (RCTs) among adults that were ≥ 12 weeks and compared a commercial program to usual care (UC) or lifestyle counseling. We also included trials from the prior review that met these criteria. Paired investigators screened results to assess eligibility, then abstracted data on study design, population characteristics, and weight. We synthesized data qualitatively by program.

RESULTS: Overall, we included 27 RCTs. Weight Watchers (WW): As compared to UC, WW groups had 2.2–10 % greater mean percent weight loss at all time points (8 RCTs). There were inconsistent effects when comparing WW to counseling (2 RCTs). Atkins: As compared to counseling, Atkins groups had 0.8–6.2 % greater mean percent weight loss at 3–6 months (6 RCTs); however, there were no significant between group differences at 12 months or beyond. Jenny Craig (JC): One RCT compared JC to UC, where JC resulted in 7.5 % and 6.4 % greater mean percent weight loss at 6 and 12 months, respectively. Slim-Fast (SF): As compared to UC, SF groups had 6.3–9.7 % greater mean percent weight loss at 3–6 months (4 RCTs). There were inconsistent effects when comparing SF to counseling (3 RCTs). Nutrisystem: One RCT compared Nutrisystem to UC, where Nutrisystem resulted in 6.8 % greater mean percent weight loss at 6 months.

CONCLUSIONS: While commercial weight loss programs can help patients lose weight, these programs may not be superior to counseling. Clinicians may consider these programs when clinic-based options are unavailable.

COMMUNICATION FROM URGENT CARE CENTERS TO EMERGENCY DEPARTMENTS Rebekah Gardner^{1,2}; Esther Choo¹; Stefan Gravenstein^{4,2}; Rosa Baier^{2,3}. ¹Alpert Medical School of Brown University, Providence, RI; ²Healthcentric Advisors, Providence, RI; ³Brown University School of Public Health, Providence, RI; ⁴Case Western Reserve University, Cleveland, OH. (*Tracking ID #1942530*)

BACKGROUND: Care transitions occur when patients move from one healthcare setting or provider to another (e.g., when a hospital patient is discharged). Although successful transitions require timely, accurate and sufficient communication of clinical information, such communication is inconsistent and there are few established guidelines outside of the hospital setting. Consistent, high-quality communication is particularly important during and after visits to urgent care centers (UCCs). However, our review of the medical literature revealed no prior investigation on the quality and consistency of communication from UCCs to emergency departments (EDs). Our aim was to assess the quality, consistency and effectiveness of healthcare communication between UCCs and EDs during care transitions.

METHODS: We administered a short anonymous survey to a convenience sample of emergency medicine physicians in Rhode Island. We contacted department chairs at the state's 13 acute-care hospitals and asked them to distribute the electronic survey to their emergency medicine physicians (MDs or DOs in active practice). The survey asked practitioners to characterize the frequency and completeness of the information they receive from UCCs. We used descriptive statistics to characterize survey respondents, their perceptions about UCC to ED information transfer and their preferences for future communication. We also conducted a qualitative analysis of open-ended questions.

RESULTS: Eleven (84.6 %) ED chairs agreed to distribute the survey. Approximately half (48.7 %) of the 199 emergency medicine physicians at these 11 hospitals responded. Most were attending physicians (62.1 %) and had ≥ 10 years of experience in the ED (55.7 %). Overall, respondents' perceptions of the consistency, relevancy and usefulness of the information they receive

from UCCs varies widely. For example, despite expressing strong preferences to receive this type of information, respondents report receiving reason for referral 72.0 % of cases and a copy of the chart in 60.6% of cases. Receipt of contact information (52.3 %) and phone calls to the ED (42.0 %) are lower. Conversely, respondents report rarely communicating ED findings back to UCCs (16.7 %). Comments reveal frustration with poor information transfer, particularly when the UCC clinicians are unavailable, and a desire to standardize or formalize communication expectations.

CONCLUSIONS: These data highlight a very real disconnect between the communication and information that emergency medicine physicians believe is necessary for providing care and the information that they receive from UCCs. Additionally, the ED providers' nearly universal lack of communication back to the urgent care center following treatment of the admitted patient suggests the absence of a closed communication loop between these care settings. Our findings speak to the importance of establishing communication standards and of including UCCs in ongoing initiatives to improve patient care transitions and experiences.

COMMUNITY COLLEGE PATHWAYS TO MEDICAL SCHOOL: EXPLORING THE EXPERIENCES OF LATINO STUDENTS Efrain Talamantes¹; Carol Mangione^{2,3}; Karla Gonzalez³; Gery Ryan⁴; Alejandro Jimenez⁵; Fabio R. Gonzalez⁶; Seira Greenwood⁷; Gerardo Moreno^{2,8}. ¹Department of Veteran Affairs and the University of California, Los Angeles, Los Angeles, CA; ²University of California, Los Angeles, Los Angeles, CA; ³University of California, UCLA, Los Angeles, CA; ⁴RAND Health, Santa Monica, CA; ⁵University of California, San Francisco, San Francisco, CA; ⁶San Jose City College, San Jose, CA; ⁷University of California, Los Angeles, Los Angeles, CA; ⁸University of California, Los Angeles, Los Angeles, CA. (*Tracking ID #1940189*)

BACKGROUND: The community college is an essential pathway to medical school for Latino and low-income students, and contributes to a diverse physician workforce. There has been an increase in community college enrollment for the last several decades. The objective of this study was to explore the facilitators and barriers Latino pre-medical students face when they attend a community college.

METHODS: Participants included 48 Latino pre-medical students who were enrolled at or previously attended a California community college, and 20 stakeholders who directly advise and support these students. We conducted five focus groups (4 of undergraduate students who were currently enrolled or previously attended a community college, and 1 of medical school students who attended a community college) and 20 semi-structured interviews with counselors, advisors, and teachers based at the community college, and medical school admissions staff and faculty from several California medical schools. Focus groups and interviews were digitally audiotaped, transcribed, and reviewed independently by two coders. Standard qualitative content-analysis methods were used to identify major themes and a third investigator adjudicated disagreements.

RESULTS: Results revealed the following major facilitator themes 1) pre-medical enrichment programs 2) pre-medical specific advising 3) Latino physician mentors and 4) family support for pursuing a pre-medical education. Major barrier themes included: 1) a perception that college was not affordable 2) poor high school academic preparation 3) lack of family support and responsibilities that compete with time to study and 4) limited counseling or advising. The financial burden of attending a community college required many students to take low-paying jobs to pay for tuition, books, housing, and transportation, while taking rigorous science coursework. Enrichment programs such as Math Engineering Science Achievement (MESA) play an important role in providing community college students with academic tutorials and advising, but are not readily accessible to students because of capacity constraints and stringent financial verification requirements. Stakeholders also indicate the need for a more comprehensive and sustainable pre-medical enrichment programs that include financial support and pre-medical counseling for low-income students, many of whom were the first in their family to attend college.

CONCLUSIONS: This is the first qualitative study that explores the role the community college as a pathway to medical school for Latino pre-medical students. We identified a number of potentially mutable barriers for premedical students who attend community college. Enrichment programs and policies that decrease the financial burden of pursuing higher education potentially can mitigate many of these barriers. The significant growth in the number of Latinos at the community college pursuing premedical education represents an important part of the pipeline to increase the diversity of the physician workforce.

COMMUNITY COLLEGE PATHWAYS: IMPROVING THE U.S. PHYSICIAN WORKFORCE PIPELINE Efrain Talamantes¹; Carol Mangione^{2,3}; Karla Gonzalez²; Alejandro Jimenez⁴; Fabio R. Gonzalez⁵; Gerardo Moreno^{2,6}. ¹Department of Veteran Affairs and the University of California, Los Angeles, Los Angeles, CA; ²University of California, Los Angeles, Los Angeles, CA; ³University of California, UCLA, Los Angeles, CA; ⁴University of California, San Francisco, San Francisco, CA; ⁵San Jose City College, San Jose, CA; ⁶University of California, Los Angeles, Los Angeles, CA. (*Tracking ID #1939846*)

BACKGROUND: Diversity in the physician workforce increases healthcare access for underserved populations, improves culturally and linguistically appropriate care, and better prepares all physicians to serve the needs of a diverse population. How we can achieve that diversity, however, is not well understood. One answer may lie in where students attain the undergraduate training they need before entering medical school. There are no studies that clarify how or if the undergraduate pathway contributes to a diverse physician workforce that is interested in serving underserved communities. Furthermore, the Community College (CC) as a pathway to medical school has not been explored at all.

METHODS: We performed a cross-sectional analyses of the 2012 Association of American Medical Colleges matriculant and applicant files, and the Matriculating School Questionnaire to assess bivariate associations between student characteristics and participation in a CC pathway. We also estimate the association between participation in a CC pathway and acceptance to medical school, intention to practice in underserved areas or work primarily with minority populations using multivariate logistic regression to adjust for confounders.

RESULTS: One third of applicants ($N=40,491$) and matriculants ($N=17,518$) to U.S. allopathic medical schools used a CC. A higher proportion of Latino matriculants used the CC pathways (34 % vs. 27 %, $P<0.001$), compared to Whites. Matriculants who attended a CC after graduating from high school and before transferring to a 4-year university were more likely to have parents without a college education (34 % vs. 13.4 %, $P<0.001$), had lower odds of acceptance into medical school (adjusted odds ratio [AOR]=0.68, 95 % CI 0.61 to 0.75, $P<0.05$) and higher odds (AOR=1.26, 95 % CI 1.04 to 1.53, $P<0.05$) of intentions to practice in underserved communities, compared to medical students who never attended a CC, after adjusting for covariates.

CONCLUSIONS: The CC pathways are essential for underrepresented minorities and students who have intentions to practice in underserved communities. While many recruitment and outreach efforts are strictly targeted at 4-year universities, there may be ample opportunities to support students pursuing careers in medicine that use the community college pathways and nurture their desire to ultimately practice medicine in an underserved community.

COMMUNITY HEALTH CENTER PATIENTS' ATTITUDES AND PREFERENCES REGARDING RECEIVING PREVENTIVE SERVICE OUTREACH MESSAGES Tiffany Brown; Shira N. Goldman; Ji Young Lee; Muriel Jean-Jacques; Shreya Shah; Stephen D. Persell. Northwestern University, Feinberg School of Medicine, Chicago, IL. (*Tracking ID #1938151*)

BACKGROUND: As community health centers (CHC) work to improve their quality of care for clinical preventive services, one possible strategy is outreach to patients who are due for certain services. Multiple studies have evaluated outreach for immunizations and cancer screenings among vulnerable populations. This proactive outreach may be particularly beneficial for CHC patients who may be less likely to have regular preventive service visits and for whom preventive services may be a lower priority if limited clinical encounter time is focused on acute and chronic health issues. However, little is known about CHC patients' attitudes towards this type of outreach and how they prefer to be contacted with these messages. Our objective was to understand CHC patients' attitudes and preferences regarding receiving clinical preventive services outreach messages from their CHC. We report interim results from a survey of CHC patients.

METHODS: As part of a larger project evaluating the effectiveness of an outreach intervention to promote the prevention of cardiovascular disease (CVD), we conducted telephone surveys with patients within three CHC systems; two in Chicago, IL and one in Flagstaff, AZ. Patients were eligible if they had been randomized to intervention arm of a randomized controlled trial of mailed and telephone outreach to individuals at increased risk for the development of CVD. Eligibility criteria were: men ≥ 35 and women ≥ 45 years old, a 10-year risk of coronary death or myocardial infarction (based on Framingham Risk Score) of at least 10 %, and a visit to CHC within 6 months prior to randomization. The survey was performed 1 year after the intervention was delivered. The survey assessed patient attitudes towards receiving messages about three preventive services: (1) influenza

vaccination (2) cancer screenings (3) and primary prevention of CVD. In addition, participants were asked how they preferred to be contacted with these messages. Participants responded to Likert items ranging from 1 (strongly disagree) to 5 (strongly agree). Demographic items were also included.

RESULTS: Among eligible subjects with the recruitment protocol for the survey completed, $n=60$ completed interviews (56 % response rate). The majority of participants were male (91.7 %), 48.3 % were black and 38.3 % were white, 68.9 % had a high school degree or higher. Participants expressed agreement with statement that it was a good idea for CHC to let them know when they were due for flu shot (mean 4.3, standard deviation [SD] 1.3), due for cancer screenings (mean 4.7, SD 0.8), and if there were things they could do to lower their risk of developing CVD (mean 4.7, SD 0.7). Patients expressed agreement with wanting to be called by health center staff member (mean 4.1, SD 1.4), and receiving information by mail (mean 4.3, SD 1.3), however they expressed disagreement when asked about receiving a text message (mean 2.5, SD 1.6) or an email message (mean 2.2, SD 1.6). Participants reported strong agreement with preference to come in to discuss recommended services with their provider in person (mean 4.4, SD 1.0).

CONCLUSIONS: CHC patients in our sample report positive attitudes towards receiving outreach messages about their preventive service needs from their clinic. Participants prefer to receive these messages by telephone call or mail as opposed to text message or email. These results may have limited generalizability given specific eligibility criteria and our small, primarily male sample. These data will help inform future outreach efforts to CHC patients to promote important clinical preventive services.

COMPARATIVE EFFECTIVENESS OF A PRACTICE-BASED TRIAL OF BLOOD PRESSURE CONTROL IN BLACKS: IS LESS MORE? Antoinette Schoenthaler¹; Jeanne Teresi²; Leanne Luerassi¹; Stephanie Silver²; Jian Kong²; Taiye Odedosu¹; Gbenga Ogedegbe¹. ¹New York University School of Medicine, New York, NY; ²The Hebrew Home at Riverdale, Riverdale, NY. (*Tracking ID #1929818*)

BACKGROUND: The efficacy of interventions targeted at comprehensive therapeutic lifestyle changes (TLC) is well proven in reducing blood pressure (BP) among patients with hypertension (HTN). However their translation to primary care practices is limited, particularly among black patients with HTN, who share a disproportionately greater burden of HTN-related outcomes. More importantly, the comparative effectiveness of single session TLC interventions on BP reduction in primary care practices is unproven. The aim of this vanguard trial was to evaluate the comparative effectiveness of a practice-based comprehensive lifestyle intervention targeted at recommended TLC, delivered through group-based counseling and motivational interviewing (MINT), versus a single session counseling on lifestyle modification (SSC) in reducing BP at 6 months among low-income, blacks with uncontrolled HTN.

METHODS: A total of 194 black patients were randomized to either the MINT-TLC or SSC group. The comprehensive lifestyle intervention (MINT-TLC) was based on established clinical practice guidelines for prevention and treatment of HTN, which recommends weight loss (if overweight), regular physical activity, limiting and/or reducing sodium and alcohol intake, and eating a low-fat diet that is rich in fruit and vegetables. Patients in the MINT-TLC group attended 10 weekly group classes (intensive phase) focused on TLC; followed by 3 monthly individual MINT sessions (maintenance phase) delivered by trained Health Educators. Patients in the SSC condition received a single 30-minute individual counseling session on therapeutic lifestyle changes at the baseline visit by trained study staff. To match the MINT-TLC group for content of intervention material, those in the SSC group also received print versions of the intervention curriculum that was distributed in the group classes. The primary outcome was change in systolic BP and diastolic BP at 6 months assessed with an automated BP monitor (WatchBP). The average of three BP readings was used as the primary outcome measurement, following standard American Heart Association guidelines. The primary analyses examined systolic and diastolic BP separately based on intent-to-treat. A repeated measures mixed model approach was used to account for continuous primary outcomes collected at three waves (baseline, 3 and 6 months), and clustering within primary care providers. The post-treatment values of continuous outcomes were modeled as functions of baseline values, treatment and the interaction of baseline and treatment.

RESULTS: The mean age of all patients was 57 years, 50 % were women, 69 % had income $<\$20,000$ /year with mean baseline BP 147.4/89.3 mmHg. Average attendance at the group-based classes in the MINT-TLC condition was 50 %; 35 % of patients completed all three individual MINT sessions. There was non-significant reduction in systolic and diastolic BP for the MINT-TLC compared to the SSC group. The net adjusted reduction in systolic BP by 6 months was 12.9 mmHg for the SSC vs.

9.5 mmHg for the MINT-TLC group. The reduction in diastolic BP was 7.6 mmHg for the SSC vs. 7.2 mmHg for the MINT-TLC group.

CONCLUSIONS: Despite the non-significant between-group difference in BP reduction in the intensive group counseling with multiple office visits versus the single counseling session plus educational material both groups exhibited comparable and clinically meaningful BP reduction. Evaluation of the effectiveness of the interventions in a large Phase 3 trial is warranted in this patient population. Trial Registration: Clinicaltrials.gov NCT01070056

COMPARING CLINICIANS' PERCEPTION OF THEIR OWN AND THEIR PEERS' ANTIBIOTIC PRESCRIBING TO ACTUAL ANTIBIOTIC PRESCRIBING FOR ACUTE RESPIRATORY INFECTIONS IN PRIMARY CARE

Harry Reyes Nieva^{1,2}; **Jason N. Doctor**³; **Mark W. Friedberg**^{1,4}; **Caroline Birks**^{2,5}; **Yelena Kleyner**⁶; **Julie Fiskio**¹; **Lynn A. Volk**⁶; **Jeffrey A. Linder**^{1,2}. ¹Brigham and Women, Boston, MA; ²Harvard Medical School, Boston, MA; ³University of Southern California, Los Angeles, CA; ⁴RAND Corporation, Boston, MA; ⁵Massachusetts General Hospital, Boston, MA; ⁶Partners Healthcare System, Boston, MA. (*Tracking ID #1941741*)

BACKGROUND: Primary care clinicians often prescribe inappropriate antibiotics for acute respiratory infections (ARIs). Inappropriate prescribing may be a result of differences in clinicians' perceptions of their own antibiotic prescribing rates, perceptions of their peers' antibiotic prescribing rates, and actual antibiotic prescribing rates.

METHODS: Using a mixed methods approach, we first surveyed 269 primary care clinicians in the Partners Primary Care PBRN about their agreement with antibiotic prescribing guidelines for non-specific upper respiratory infections (URIs), pharyngitis, acute bronchitis, and sinusitis. For each of these diagnoses, the survey asked clinicians to estimate ARI antibiotic prescribing rates for themselves and their peers in five categories: 0 %–20 %, 21 %–40 %, 41 %–60 %, 61 %–80 %, or 81 %–100 %. We then calculated respondents' actual ARI antibiotic prescribing rates between May 2011–April 2012 using billing and electronic health record data and grouped them using the same five antibiotic prescribing rate categories as the survey. We used the Kruskal-Wallis test to compare respondents' estimates of their own antibiotic prescribing rates to that of their peers.

RESULTS: 169 of 269 (63 %) primary care clinicians in 23 practices responded to our survey. Mean respondent age was 49 years, 60 % were women, and 85 % were physicians. We linked respondents to 20,025 ARI visits. Clinicians overwhelmingly agreed with antibiotic treatment guidelines for non-specific upper respiratory infections (100 % of clinicians), pharyngitis (95 %), acute bronchitis (92 %), and sinusitis (98 %). For non-specific URIs, the proportion estimating antibiotic prescribing rates in the five categories (i.e., 0 %–20 %, 21 %–40 %, 41 %–60 %, 61 %–80 %, or 81 %–100 %) for themselves was 72 %, 19 %, 7 %, 2 %, and 0 %, respectively, and for their peers was 37 %, 41 %, 17 %, 5 %, and 0 %, respectively ($p <0.001$). The actual non-specific URI antibiotic prescribing rate was 34 %; 75 % underestimated and 3 % overestimated their own rate. For pharyngitis, the proportion estimating antibiotic prescribing rates in the five categories for themselves was 81 %, 13 %, 2 %, 2 %, and 1 %, respectively, and for their peers was 63 %, 26 %, 8 %, 3 %, 0 %, respectively ($p <0.001$). The actual pharyngitis antibiotic prescribing rate was 59 %; 71 % underestimated and 0 % overestimated their own rate. For acute bronchitis, the proportion estimating antibiotic prescribing rates in the five categories for themselves was 48 %, 31 %, 14 %, 6 %, and 1 %, respectively, and for their peers was 21 %, 40 %, 27 %, 10 %, and 2 %, respectively ($p <0.001$). The actual acute bronchitis antibiotic prescribing rate was 76 %; 76 % underestimated and 1 % overestimated their own rate. For sinusitis, the proportion self-reporting antibiotic prescribing rates in the five categories for themselves was 35 %, 41 %, 19 %, 3 %, and 2 %, respectively, and for their peers was 13 %, 40 %, 33 %, 13 %, 1 %, respectively ($p <0.001$). The actual sinusitis antibiotic prescribing rate was 88 %; 86 % underestimated and 2 % overestimated their own rate.

CONCLUSIONS: Clinicians agree with ARI antibiotic treatment guidelines. Clinicians think their peers prescribe antibiotics at higher rates than themselves. Clinicians' estimates of their own and their peers' prescribing rates are lower than actual prescribing rates. To reduce inappropriate antibiotic prescriptions for ARIs, future interventions might correct clinicians' misperceptions of their own and their peers' antibiotic prescribing rates.

COMPARING WARFARIN ANTICOAGULATION MEASUREMENTS

Zayd A. Razouki^{1,2}; **James Burgess**³; **Shibei Zhao**²; **Adam Rose**^{1,2}. ¹Boston Medical Center, Boston, MA; ²Bedford VA Medical Center, Bedford, MA; ³Boston University School of Public Health, Boston, MA. (*Tracking ID #1932592*)

BACKGROUND: Percent time in therapeutic range (TTR) is a measure of anticoagulation intensity, while INR variability is a measure of anticoagulation stability. Both are valid intermediate measures for warfarin anticoagulation control that predict warfarin associated complications (WAC, i.e. ischemic stroke, major bleeding including fatal bleeding) in patients with atrial fibrillation. However, less is understood about how these two measures complement each other when used together. This study examines how TTR and INR variability predict WAC, and compares them to a composite measure that combines both of them.

METHODS: We included 40,404 patients anticoagulated for atrial fibrillation, age 65+, within the Veterans Health Administration. We used ICD 9 codes to define WAC as our outcome. For each patient, we calculated TTR using Rosendaal's method, INR variability using Fihn's method, and constructed a composite measure (CM) using an equally weighted method, adding standardized TTR to the standardized log-transformation of INR variability. High TTR and low log INR variability represent good anticoagulation. Therefore, we converted the direction of log INR variability to make it consistent with TTR. We divided our sample into quintiles for each measure based on their level of anticoagulation control (i.e. very poor, poor, moderate, good and excellent control). We used Cox regression models to predict WAC; hazard ratios were compared across quintiles of TTR, log INR variability and the intermediate composite measure. The reference group was the quintile of "excellent control"

RESULTS: The composite measure predicted ischemic stroke better than TTR and log INR variability in all quintiles, especially in the first quintile of "very poor control" (HR=2.43 vs. HR=2.10 and HR=1.74, respectively). CM and TTR predicted major bleeding similarly except in the second quintile of "poor anticoagulation" (CM HR=1.57 vs. TTR HR=1.35); but both measures were generally better than log INR variability in all quintiles. CM was superior to both TTR and log INR variability when predicting fatal bleeding across all quintiles, especially in the "very poor control" quintile (HR=3.04 vs. HR=2.49 vs. HR=2.18, respectively) and the moderate control quintile (HR=1.45 vs. HR=1.19 vs. HR=1.19 respectively). We were not able to calculate p values to compare whether differences in hazard ratios were statistically significant because individual patients were not distinctly separated across the three studied measures.

CONCLUSIONS: Our composite measure encompasses two aspects of anticoagulation control, namely intensity and stability. Our findings suggest its usefulness in measuring anticoagulation control. It has an advantage in predicting ischemic stroke and fatal bleeding over TTR and log INR variability but it is only better than the log INR variability in predicting major bleeding.

COMPARISON OF EPIGENETIC VERSUS INTENSIVE CHEMOTHERAPY FOR NEWLY DIAGNOSED ELDERLY ACUTE MYELOID LEUKEMIA PATIENTS ≥60 YEARS OLD

Neha Gupta¹; **Shipra Gandhi**¹; **Austin Miller**²; **Laurie A. Ford**³; **Elizabeth A. Griffiths**³; **James E. Thompson**³; **Meir Wetzel**³; **Eunice Wang**³. ¹University at Buffalo, Buffalo, NY; ²Roswell Park Cancer Center, Buffalo, NY; ³Roswell Park Cancer Center, Buffalo, NY. (*Tracking ID #1938243*)

BACKGROUND: Epigenetic therapy (Epi) with the hypomethylating agents (eg. azacitidine and decitabine) is increasingly being utilized for induction treatment of elderly Acute myeloid leukemia (AML) patients based on studies demonstrating both tolerability and prolonged survival. By contrast, standard intensive chemotherapy (IC) with cytarabine and daunorubicin effectively induces remission in many individuals but is associated with significant toxicity and higher mortality. We compared our institute's experience with Epi vs. IC for the upfront treatment of newly diagnosed AML patients ≥60 years old.

METHODS: We performed a retrospective chart review of 164 patients ≥60 year old with newly diagnosed AML at Roswell Park Cancer Center between 3/2008 and 2/2013. $N=84$ patients received IC, and $n=82$ patients received Epi. Kaplan Meier method, log rank test, and multivariate analysis with cox proportional hazard models were used to assess overall survival (OS) and correlation with covariates.

RESULTS: Baseline patient characteristics demonstrated a difference in median age of patients in each group (IC 67 years vs. Epi 75 years; $p <0.01$). All other factors were comparable. At our center, older AML patients receiving IC had superior complete response at any time point (CRatp) (43 % vs. 21 %; $p <0.01$). IC also resulted in a longer median OS compared to Epi (10.6 vs. 7.9 months; $p = 0.01$). Thirty-day mortality and leukemia-free survival (LFS) were similar across the two groups (IC 10 % vs. Epi 11 %; $p = 0.8$; 11.2 vs. 9.3 months; $p = 0.47$ respectively). Choice of Epi drug (Azacitidine vs. Decitabine) did not impact results. In multivariate Cox regression analysis, older age, higher ECOG score, increased peripheral blasts, and poor-risk cytogenetics were independently associated with inferior survival.

CONCLUSIONS: Our results suggest that IC and Epi represent clinically equivalent approaches for the upfront treatment of older AML patients. In spite of significantly higher complete response (CR) and overall response rate (ORR) in the IC group, our

finding of improved OS following IC vs. Epi was not substantiated in multivariate analysis. This finding suggests that difference in response of two agents in univariate analysis may be explained by the comparatively younger age of patients in the IC group. Leukemia-free survival and 30-day mortality were the same for IC vs. Epi-treated patients, as were all response and survival outcomes in the poor-risk cytogenetics subgroup. These data highlight the growing need for prospective clinical trials to conclusively determine the respective roles of IC vs. Epi therapy in older AML patients.

COMPARISON OF READABILITY OF PATIENT DISCHARGE INSTRUCTIONS WITH AND WITHOUT USE OF DISEASE-SPECIFIC TEMPLATES
Stephanie Mueller; Kyla Giannelli; Robert Boxer; Jeffrey L. Schnipper. Brigham and Women, Boston, MA. (*Tracking ID #1937804*)

BACKGROUND: In the United States, 21–23 % of the adult population have low literacy, and an additional 27 % have low health literacy (difficulty understanding written health education materials). Written materials are commonly used to communicate with patients at time of discharge, but can vary in readability level. We evaluated the association of the use of templated discharge instructions with readability scores of discharge instructions provided to patients at hospital discharge.

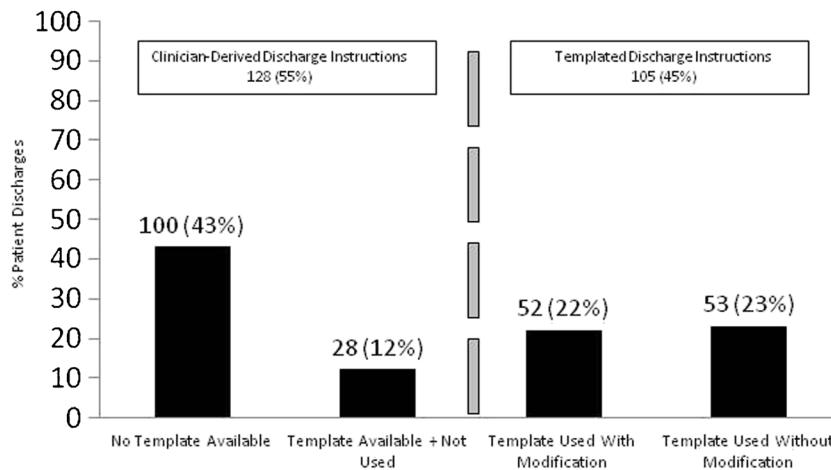

METHODS: We performed a retrospective cohort study of patients discharged from an academic medical center. Data were obtained from electronic medical records. Patients were eligible for inclusion if discharged from any inpatient service to home between October, 2011 and September, 2012, following initiation of a web-based “discharge module,” a quality improvement initiative to improve written communica-

cation at discharge, that included optional use of disease-specific templated discharge instructions. We examined the frequency of use of the templated discharge instructions. We then evaluated readability using two common measures: Flesch-Kincaid Grade Level (FKGL) and Flesch Reading Ease Level (FREL) in discharges that provided templated discharge instructions (with or without modification) vs. discharges that provided clinician-derived discharge instructions (where templated instructions were available and not used or were unavailable for the specific discharge diagnosis).

RESULTS: Of the 233 randomly selected patient discharges, 105 (45.1 %) provided templated discharge instructions and 128 (54.9 %) provided clinician-derived discharge instructions (Figure 1). The mean FKGL of templated discharge instructions was grade 5.6 vs. 7.6 for clinician-derived discharge instructions ($p < 0.001$). The mean FREL of templated discharge instructions was 71 vs. 57.4 for clinician-derived discharge instructions ($p < 0.001$). In subgroup analysis, FKGL of discharge instructions did not differ significantly when templated instructions were modified versus used without modification (5.8 vs. 5.5, $p = 0.15$). FREL of modified templated discharge instructions was 69.1 vs. 72.9 for templated instructions without modification ($p = 0.02$).

CONCLUSIONS: We found that we still lack many disease-specific templated discharge instructions within our “discharge module,” the major reason for clinicians to create discharge instructions themselves. Compared to discharges that used templated instructions, those that did not had significantly lower readability scores (higher FKGL and lower FREL). Modification of templated instructions, which may lead to more customized messages, did not appreciably detract from readability. Our findings suggest that templated instructions are more literacy friendly than clinician-derived discharge instructions.

Figure 1: Use of Disease-Specific Templated Discharge Instructions

CONTINUING MEDICAL EDUCATION (CME) PARTICIPANTS’ USE OF SPECIFIC TYPES OF SOCIAL MEDIA (SM) AND ASSOCIATION WITH ATTITUDES FOR USING SM IN CME Alexander Vengerovsky; Amy T. Wang; Jayawant N. Mandrekar; Nicole P. Sandhu; Christopher M. Wittich; Karen F. Mauck; Thomas J. Beckman. Mayo Clinic, Rochester, MN. (*Tracking ID #1939285*)

BACKGROUND: Most research on social media (SM) in medicine pertains to issues of professionalism. One recent study found that continuing medical education (CME) course participants who use SM tend to be younger and favor the use of SM for enhancing CME learning. However, the potential link between the specific types of SM and participants’ views on using SM for CME remains unknown. Therefore, we determined what categories of SM are used by CME participants, along with the relationship between categories of SM use and favorable attitudes on using SM for CME.

METHODS: This was a cross-sectional survey of 539 participants at a Mayo Clinic Internal Medicine CME course in 2011. The Social Media Use and Perception Instrument (SMUPI) consisted of 10 items (5-point scales), and has been shown to have strong content, internal structure and criterion validity. Participants were surveyed regarding their demographic characteristics and individual use of SM. We also grouped types of SM into

the following categories: professional (LinkedIn, Doximity, or Sermo), social (Facebook, Google+, Myspace, or Twitter), informational (blogs, wikis, podcasts, or StumbleUpon), and media (YouTube, Skype, Picasa, or Flickr). Comparisons of SMUPI scores for users versus non-users of each type of SM, and within categories of SM (professional, social, informational, and media), were calculated using the Wilcoxon Ranked sum test. The threshold for statistical significance was set at $p < 0.05$.

RESULTS: Of 539 CME participants, 327 (response rate = 61 %) completed the survey and 291 (89 %) reported using SM. CME course participants’ had generally favorable attitudes towards SM (Average SMUPI score 3.12). When comparing users and non-users of specific types of SM, higher SMUPI scores existed for users of Facebook (3.42 vs. 3.00, $p < 0.0001$), Google+ (3.50 vs. 3.08, $p < 0.0001$), Twitter (3.74 vs. 3.19, $p = 0.003$), LinkedIn (3.53 vs. 3.18, $p = 0.007$), Wikis (3.38 vs. 3.12, $p = 0.02$), and YouTube (3.32 vs. 3.09, $p = 0.02$). There were no significant SMUPI score differences for users versus non-users of Skype, blogs, podcasts, and Picasa. Finally, higher SMUPI scores were demonstrated for users versus non-users in the SM categories of professional (3.58 vs. 3.17; $p = 0.001$), social (3.37 vs. 2.82; $p < 0.0001$), and informational (3.35 vs. 3.06; $p = 0.008$).

CONCLUSIONS: We are unaware of previous studies on the relationships between types of SM use and favorable attitudes towards utilizing SM for CME learning. Our

results suggest that users of Facebook, Google+, LinkedIn, Twitter, and Wikis had the most positive attitudes regarding the use of SM in CME. Interestingly, these particular types of SM incorporate adult-learning principles of real-time interactivity and adaptability in order to optimize communication and community-building. We suggest that as CME directors increasingly utilize SM, they should focus on incorporating interactive types of SM into their CME courses.

CONTINUITY IN A VA PATIENT-CENTERED MEDICAL HOME REDUCES EMERGENCY DEPARTMENT VISITS Krisda Chaiyachati^{1,2}; Kirsha S. Gordon³; Theodore Long⁴; Ali M. Khan⁶; Forrest Levin^{3,5}; Emily M. Meyer²; Amy C. Justice^{1,2}; Rebecca Brienza^{1,2}. ¹Yale University School of Medicine, New Haven, CT; ²VA Connecticut Healthcare System, West Haven, CT; ³VA Connecticut Healthcare System, West Haven, CT; ⁴Yale University School of Medicine, New Haven, CT; ⁵Evergreen Design, Guilford, CT; ⁶Iora Health, Brooklyn, NY. (*Tracking ID #1922254*)

BACKGROUND: One major goal of the Patient Aligned Care Team (PACT), the VA's Patient-Centered Medical Home (PCMH) model, is to improve continuity of care between patient and provider, partly because poor continuity is believed to contribute to the inappropriate use of healthcare services like the emergency department (ED). Hypothesizing that patients with high continuity of care levels would visit the ED less, we sought to model patient and clinical factors associated with varying continuity levels and assess the association between high levels of continuity and the frequency of ED visits in the year after the initial implementation of PACT teams at Connecticut's West Haven VA (WHVA).

METHODS: We performed a retrospective analysis of patients with established care at the WHVA primary care clinic from March 1, 2011 to February 29, 2012. We defined continuity as a patient seeing their assigned primary care provider (PCP) or trainee—resident physician or nurse practitioner. Using a multivariable regression model we determined the association between continuity and the frequency of ED visits, controlling for demographics, patient assignment to a trainee, comorbidities, having outside insurance, military service period, and distance from the ED. Additional models analyzed individuals who had at least one continuity visit in the study year to determine the impact of levels of continuity on ED utilization.

RESULTS: Veterans meeting inclusion criteria totaled 13,495 individuals with 42,969 total Clinic visits. Among those, 3185 (24 %) used the WHVA ED for 15,458 total ED visits. After controlling for covariates and potential confounders, continuity with an assigned PCP was independently associated with a 46 % reduction in the odds of using the WHVA ED [adjusted odds ratio (AOR) 0.54; 95 % confidence interval (CI): 0.41–0.71]. In the subset of patients having at least one primary care visit with continuity, those with medium (33–50 % of visits) and high continuity (>50 % of visits) levels were 30 % less likely (AOR 0.70; 95 % CI: 0.54–0.92) and 41 % less likely (AOR 0.59; 95 % CI: 0.25–0.76) to use the ED compared to patients with low continuity (<30 % of visits). Controlling for low (<3 visits/year) versus high (≥3 visits/year) primary care users did not significantly alter the impact of continuity on ED utilization. Patients assigned to a trainee were associated with lower ED utilization (AOR 0.78; 95 % CI: 0.69–0.89).

CONCLUSIONS: Improved continuity of care between patients and providers, including trainees, is associated with decreased ED utilization within the WHVA's PACT system. To our knowledge, this is the first detailed analysis of continuity within a large PCMH model and assessment of the association between continuity and ED utilization. As outpatient centers and health systems adapt PCMH models to their specific setting, understanding the impact of patient-centered care indicators, like continuity, on healthcare utilization patterns and patient outcomes will be important for understanding PCMH components that may ultimately reduce health system costs.

CONTINUITY VISITS - A MODEL TO IMPROVE RELATIONAL CONTINUITY BETWEEN PATIENTS AND THEIR LONGITUDINAL PHYSICIANS DURING ACUTE HOSPITAL ADMISSIONS Ryan Thompson; Chrisanne Sikora; Maria Veo; Keith Jennings; Timothy Ferris. Massachusetts General Hospital, Boston, MA. (*Tracking ID #1941793*)

BACKGROUND: With the rise of hospital medicine, and professional pressures facing ambulatory-based physicians, fewer patients are seeing the longitudinal physicians they know best when hospitalized. Research has shown that a majority of hospitalized patients feel they receive better care and experience higher levels of trust when cared for by physicians they have known over time. To address this decline in "relational continuity," we began a pilot program to incentivize physicians identified as having a longitudinal relationship with a patient to make a "Continuity Visit" during the patient's hospital admission. A secondary aim of the program is facilitate stronger clinical collaboration between hospital and ambulatory physicians based on their unique knowledge of the patient.

METHODS: A Continuity Visit is a brief one-time inpatient visit by a patient's longitudinal physician with the patient and inpatient care team. Physicians eligible to participate include primary care physicians (PCPs), specialist physicians, and hospitalist physicians (for patients readmitted within 30 days). We provide a small reimbursement to physicians who make a Continuity Visit, and document their visit in the medical record. Physicians are ineligible to participate if they are actively involved in the patient's current admission, as determined by billing data. PCPs at our institution have received automated electronic notifications of their patients' Emergency Department visits and hospital admissions for many years. We developed a parallel notification system for specialist physicians by using electronic billing data and an algorithm that identifies longitudinal relationships between patients and specialists. We also began sending hospitalists automated notifications of their 30-day patient readmissions. These electronic "continuity notifications" contain the patient's admitting diagnosis and hospital location, and a brief outline of the Continuity Visit program, including instructions on how to make and bill for a Continuity Visit. We tracked departmental variation in the number of Continuity Visits made since the launch of the program, and administered an anonymous survey to participating physicians regarding the perceived value of Continuity Visits to their patients and colleagues, and regarding their professional satisfaction with Continuity Visits.

RESULTS: Since the program's launch in January 2012, 4164 hospitalized patients received a Continuity Visit from a physician with whom they have a longitudinal relationship. Specialists from 12 different departments made and billed for 2916 of these visits (70 %), PCP's 1100 visits (26 %), and hospitalists 148 visits (4 %). Specialties with the highest volume of Continuity Visits included oncology, obstetrics, and cardiology. Comparing the first quarters of 2012 and 2013, the number of Continuity Visits increased by approximately two-fold among specialists, two-fold among PCPs, and four-fold among hospitalists. We surveyed physicians who made a Continuity Visit to one or more patients during a 3 month period (July–September 2013; n=182). Of 106 respondents (58 %), 52 were specialists, 43 were PCPs, and 8 were hospitalists. Ninety-seven percent of respondents felt that their Continuity Visit was useful to the patient visited (59 % highly useful, 38 % moderately useful; see Table 1) Eighty percent felt their Continuity Visit was useful to the patient's inpatient attending physician (37 % highly useful, 43 % moderately useful). Lastly, 96 % of physicians reported personal and/or clinical satisfaction from making the Continuity Visit (61 % highly satisfied, 35 % mostly satisfied; see Table 2).

CONCLUSIONS: Continuity Visits to hospitalized patients by their longitudinal physicians can facilitate stronger relational continuity between patients and physicians, improve collaboration between inpatient and ambulatory physicians, and improve information transfers across transitions of care. We found participating physicians to be highly satisfied with the Continuity Visit model. Further analysis is needed to assess whether the involvement of longitudinal physicians through Continuity Visits has impact on clinical and quality outcomes, including hospital length of stay, readmission rates, and standardized patient experience.

Reasons for Physician-Perceived Usefulness of their Continuity Visit to the Patient Visited (n=106)

The patient viewed your visit as an expression of interest in his or her well-being, even though you had no direct clinical responsibility for the care being provided during the hospitalization.	97.1 %
The patient viewed your visit as a "welcome surprise". Though the patient did not expect to see you, s/he was happy to know you were following up on his or her care.	53.4 %
The patient seemed neutral about your visit—h/she expressed neither positive nor negative reaction to your presence.	0.0 %
The patient seemed to view your visit as intrusive, and your involvement in the hospitalization as neither asked for nor desired.	0.0 %

* Respondents could check more than one response option

Reasons for Physician-Reported Satisfaction with Continuity Visits (n=106)

You were able to informally share clinical insight and information that improved the attending physician's care of this patient.	61.2 %
You believe that the collaborative relationship between you and the patient was enhanced by the Continuity Visit.	84.5 %
The Continuity Visit you made will improve the transition of care for this patient to the outpatient setting.	55.3 %
You are unsure if the care or treatment of this patient will be affected, positively or negatively, by the Continuity Visit.	8.7 %
You felt the time and effort required to make a Continuity Visit to this patient was not well spent.	1.9 %

* Respondents could check more than one response option

CONTRACEPTIVE USE IN WOMEN HAVING BARIATRIC SURGERY
 Rachel S. Casas; Iris Tong; Ghada Bourjeily. Warren Alpert Medical School of Brown University, Providence, RI. (*Tracking ID #1936953*)

BACKGROUND: Contraceptive counseling in women undergoing bariatric surgery is crucial due to the increased risk of adverse pregnancy and fetal outcomes in the 1 to 2 years following surgery. Women are typically advised to avoid pregnancy during this time period. Oral contraceptive pills (OCPs) are commonly used in the post surgical population, but their effectiveness may be limited by malabsorption. Intrauterine devices (IUDs) and surgical sterilization are the most effective contraceptive options for women not desiring future pregnancy. The aim of this study is to determine if women undergoing bariatric surgery are using and counseled about appropriate contraceptive options.

METHODS: A 36 question survey was sent electronically to pre- and post-surgical patients at the Center for Bariatric Surgery at the Miriam Hospital in Providence, Rhode Island. The survey consisted of questions about demographic data, contraceptive choices, and contraceptive counseling from healthcare providers. The survey did not include any questions containing patient identifying information. Included patients were aged between 18 and 44 years, sexually active with men, pre-menopausal, and lacked a history of hysterectomy or premature ovarian failure.

RESULTS: A total of 35 women completed the survey and met inclusion criteria. Overall, 30 participants (86 %) were counseled about contraceptives and 28 participants (80 %) were counseled to avoid pregnancy in the 1 to 2 years following surgery. Of the 21 women who had bariatric surgery within the last 2 years, 14 women (67 %) were using contraception, and seven women (33 %) were not. Among the seven contraceptive non-users post bariatric surgery, all were counseled to avoid pregnancy 1 to 2 years post surgery, six were counseled about contraceptive choices, and five did not desire pregnancy. Reasons stated for contraceptive nonuse in this subgroup included side effects and lack of regular partner. Of the 21 women who had bariatric surgery within the last 2 years, 11 (52 %) were using OCPs, three (14 %) were using male condoms, two (10 %) were using IUDs, and many women were using multiple forms of birth control. The majority of women chose their contraceptive methods based upon ease of use, ease of accessibility, and recommendation of healthcare provider. No pregnancy was reported following surgery.

CONCLUSIONS: While the majority of women undergoing bariatric surgery were using and counseled about contraceptives, many post surgical women were using less effective forms of contraception. Continued contraceptive counseling with a focus on the most effective methods, the IUD or sterilization for women not desiring future pregnancy, is needed in this population.

COORDINATING CANCER CARE: WHAT ORGANIZATIONS DO TO DELIVER HIGH-QUALITY BREAST CANCER CARE. A FUZZY SET QUALITATIVE COMPARISON ANALYSIS Nina A. Bickell¹; Alexandra Moss²; Ann S. McClearney². ¹Mount Sinai School of Medicine, New York, NY; ²The Ohio State University, Columbus, OH. (*Tracking ID #1938688*)

BACKGROUND: Underuse of adjuvant breast cancer treatments delivered by different specialists may be worsened by fragmented care and improved by effective coordination. To improve care coordination and adjuvant treatment delivery, we assessed approaches to coordinate cancer care at hospitals serving predominantly minority breast cancer patients, hospitals historically at higher risk for poorer quality.

METHODS: We interviewed 89 key informants ($n=58$ clinical; $n=16$ administrative; $n=12$ clerical; $n=3$ other) from 11 inner-city hospitals with high volumes of minority breast cancer patients to better understand how organizational characteristics might impact coordination of care, implementation and success of the T & F innovation. We used standard techniques to code the data from the key informant interviews and then used fuzzy set Qualitative Comparative Analysis (fsQCA) as the analytical method. For these results we focused our analyses on five conditions that had particular impact on successful implementation of the T&F innovation: handoffs; organizational attention to clinic patients; no-shows; patient-centeredness; and integrated EHRs. We then divided the hospitals into three outcome groups (<10 % underuse, 10–20 % underuse, >20 % underuse), and calibrated each of the conditions for six-value fsQCA using fuzzy set QCA methods.

RESULTS: Five organizational factors appeared particularly salient with respect to impacting coordination of adjuvant breast cancer care. First, with respect to tracking no-shows, the better sites had some way of keeping track of which no-shows actually came back and which no-shows needed to be contacted again; further, this tracking process was someone's designated job. How organizations managed handoffs in care

was also important. Handoffs at the better sites included an exchange of clinical information (e.g., doctors speaking directly to other doctors) as well as a clerical transfer of responsibility (clerks making appointments for patients with other specialties). Handoffs at the less good sites included one or none of these elements. Another key organizational factor involved the level of attention organizations paid to clinic patients. While some sites tolerated hectic, understaffed, and ineffective clinics, the better sites did not. A fifth critical factor was whether sites had an integrated EHR. We found that all the better sites had fully implemented and integrated EHRs, where providers could see what is going on with their patient in other specialties. Some sites had multiple EHRs leaving physicians unable to access needed treatment information. Finally, organizations that appeared to have a culture of patient-centeredness also appeared to have better quality of care. In our study, most of the good sites had a clear focus on trying to make things easy for the patient/the attitude that the hospital works for the patient and not the other way around.

CONCLUSIONS: As care coordination across sites and specialties is encouraged by federal law and regulation, specialty care silos and rigid communication systems still pose barriers to change. Our results suggest that organizational factors can have an important role impacting care coordination for breast cancer care, and highlight five mechanisms that may be truly critical with respect to ensuring good coordination and quality of breast cancer care.

CORRELATES OF SEXUAL SATISFACTION IN MIDLIFE WOMEN: COMMUNICATION IS KEY Holly N. Thomas^{1,2}; Rachel Hess¹. ¹University of Pittsburgh, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA. (*Tracking ID #1935614*)

BACKGROUND: Sex is an essential component of quality of life. While most studies of sex in women focus on sexual dysfunction, sexual satisfaction is just as important. Characteristics related to sexual satisfaction in women are not well-defined and likely change with aging. We used a population-based cohort of midlife and older women to define factors related to sexual satisfaction.

METHODS: The National Survey of Midlife Development in the United States (MIDUS) is a nationally representative cohort study of adults ages 28 to 84. Self-administered questionnaires collected information regarding demographics, psychosocial factors, and physical and mental health. The second wave (2004–2006) included questions about sex. Sexual satisfaction was assessed by: "How would you rate the sexual aspect of your life these days?" with a 0 (worst) to 10 (best) visual analog scale. Women who reported any sexual activity in the prior 6 months were included in the primary analyses. Descriptive statistics were used to compare sexually active and inactive women. Post-stratification weights based on race, age, and education status were used to adjust percentages to the general population. Univariable ordered logistic regression was used to assess the relationship between (1) sociodemographics, (2) relationship characteristics, and (3) physical and mental health of the woman and her partner, and the outcome (sexual satisfaction). Significant ($p<0.05$) variables were entered into a multivariable model.

RESULTS: Of the 2647 women in MIDUS, 1345 (63.6 %) were sexually active in the prior 6 months and 531 did not answer the questions regarding sex. The proportion of sexually active women decreased with age. However, among those married or living with a partner, 81.8 % were sexually active overall, and 56.7 % of women 65 and older were sexually active (Table 1). In the multivariable model, better communication with partner, higher frequency of sex, better self-rated mental health, earlier menopausal status, lack of dyspareunia, and no use of antidepressants were related to higher sexual satisfaction at the $p<0.05$ level (Table 2). At $p\leq0.002$, only communication and frequency of sex were significant (Bonferroni adjustment for multiple comparisons).

CONCLUSIONS: As long as they have a partner, a large proportion of women are sexually active in midlife and beyond. Neither age nor physical health is significantly related to sexual satisfaction in midlife women. Women who report better communication with their partners have higher sexual satisfaction. Providers caring for women should not assume that sexual satisfaction declines with aging. Improving communication with one's partner may be a key target in the treatment of sexual problems in women.

Proportion of sexually active women in MIDUS (if married or cohabitating)

Age	N	%	Weighted %
39 or less	169	97.7	96.0
40–49	414	92.4	90.4
50–59	370	86.7	87.6
60–69	221	71.5	69.4
70–79	72	48.7	42.6
80 or above	11	44.0	36.8

COST EFFECTIVENESS COMPARISON OF SCREENING STRATEGIES FOR LATENT TUBERCULOSIS INFECTION AMONG BACILLUS CALMETTE-GUERIN VACCINATED HEALTH CARE WORKERS

Mehrshid Kiazand^{1,2}; Noor Khan^{1,2}; Kenneth J. Smith^{2,3}. ¹UPMC Mercy, Pittsburgh, PA; ²University of Pittsburgh School of Medicine, Pittsburgh, PA; ³UPMC, Pittsburgh, PA. (Tracking ID #1906127)

BACKGROUND: The interferon- gamma release assay (IGRA) is recommended as an alternative to the tuberculin skin test (TST) to detect latent tuberculosis infection (LTBI). IGRA is the preferred test for Bacillus Calmette- Guerin (BCG) vaccine recipients. Despite recommendations, TST is frequently used in many institutions to screen for LTBI, regardless of previous BCG vaccination. We evaluated the cost-effectiveness of alternative strategies for LTBI detection among BCG vaccinated health care workers.

METHODS: We have designed a decision tree to compare three screening strategies in BCG recipients; (1) TST alone; (2) IGRA alone and (3) TST, if positive, then IGRA. In the base case, we assume that LTBI prevalence (assessed by TST among foreign born U.S. residents) is 18 %. In BCG vaccinated populations TST sensitivity and specificity is 71 % and 56 %, while IGRA sensitivity and specificity is 76 % and 96 %. Sixty-three percent of health care workers will accept isoniazid (INH) for LTBI treatment. The cost of TST is \$9.79 and IGRA is \$33.67. The cost of INH treatment for 9 months is \$508.95 and the average cost of managing INH related hepatitis (4 % risk) is \$539.74.

RESULTS: In the base case, the IGRA alone strategy cost \$23.62 more per person than TST followed by IGRA (\$88.87 vs. \$62.55), but IGRA alone increased the LTBI absolute detection and treatment rate by 2.5 % (8.6 % vs. 6.1 %). Thus compared to TST then IGRA, IGRA alone cost \$1053 per case detected and treated. Compared to IGRA alone, the TST alone strategy is dominated, costing more (\$168.89 vs. \$88.87, due to more false positives receiving INH) with fewer cases detected and treated. Compared to TST then IGRA, TST alone costs more than \$5500 per case. IGRA alone dominates TST alone if IGRA testing costs less than \$120. TST alone is no longer dominated and costs less than \$1000 per case, if 10 % or less of health care workers agree to INH treatment. Model results were robust to variation of other parameter values.

CONCLUSIONS: TST alone to detect LTBI in BCG vaccinated populations will likely cost more than other strategies and detect fewer cases than an IGRA alone strategy. However, IGRA alone costs more than \$1000 per additional case detected and treated compared to TST then IGRA. It is unclear if this cost is acceptable to

payers. Although not strongly recommended, IGRA after a positive TST may be more economically reasonable than other strategies in BCG recipients and worthy of future study.

COST-EFFECTIVENESS OF DECISION SUPPORT STRATEGIES FOR SAFELY REDUCING ANTIBIOTIC USE IN ACUTE BRONCHITIS

Constantinos I. Michaelidis¹; Melissa S. Kern²; Kenneth J. Smith³. ¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²Geisinger Health System, Danville, PA; ³University of Pittsburgh School of Medicine, Pittsburgh, PA. (Tracking ID #1929178)

BACKGROUND: A recent clinical trial suggests that printed (PDS) and computer decision support (CDS) strategies can safely reduce antibiotic use in management of acute bronchitis compared to usual care (UC). Yet, little is known about the cost-effectiveness of these strategies. We evaluate the cost-effectiveness of PDS and CDS strategies in safely reducing antibiotic use in management of acute bronchitis.

METHODS: We developed a clinical trial based cost-effectiveness analysis comparing three strategies for acute bronchitis management: UC, PDS and CDS. We assumed a societal perspective, 5 year program duration and 30 day time horizon after each office visit. Our cohort was the U.S. population aged 13–64 years presenting with acute bronchitis in an ambulatory setting. The primary differences between the three strategies were the added intervention costs and reduced likelihood of antibiotic use in the PDS and CDS strategies relative to the UC strategy. Estimated per patient program implementation costs in year 1 were \$1.07 in the PDS strategy and \$18.11 in the CDS strategy. We performed a base case cost effectiveness analysis and one-way and probabilistic sensitivity analyses in which the primary outcome was the societal cost per antibiotic safely avoided. We assumed that the societal willingness-to-pay (WTP) threshold was \$43 per antibiotic safely avoided based on prior estimates of the downstream hidden societal costs of antibiotic resistance attributable to each ambulatory antibiotic prescription.

RESULTS: In the base case analysis, the PDS strategy dominated both the UC and CDS strategies, with lesser total costs (PDS: \$2,614, UC: \$2,629, CDS: \$2,635) and fewer antibiotic prescriptions (PDS: 3.79, UC: 4.60, CDS: 3.95 antibiotic prescriptions) per patient over 5 years. In one-way sensitivity analyses, the PDS strategy dominated the UC strategy across all tested parameter values except when antibiotics reduced the duration of work loss by ≥0.1 days (base case: 0.0 days) or cost ≤\$10 (base case: \$30). The PDS strategy dominated the CDS strategy across all tested parameter values except when the adjusted odds of antibiotic use during the intervention period relative to baseline was ≥0.64 in the PDS strategy (base case: 0.57) or ≤0.57 in the CDS strategy (base case: 0.64). The PDS strategy cost less than the societal WTP threshold (\$43 per antibiotic safely avoided) across all tested parameter values except when antibiotics reduced the duration of work loss by ≥0.5 days (base case: 0.0 days). The analysis was not sensitive to variation in the costs of physician education or patient educational brochures in the PDS and CDS strategies, posters in the PDS strategy or electronic medical programming in the CDS strategy. In a probabilistic sensitivity analysis, varying all parameters simultaneously, the probability of the PDS strategy being preferred at a societal WTP threshold of \$43 per antibiotic safely avoided was 66.4 %. The PDS strategy was preferred across all thresholds from \$0–\$100 per antibiotic safely avoided.

CONCLUSIONS: A printed decision support strategy to safely reduce antibiotic use in ambulatory management of acute bronchitis is likely to be less costly and more effective than usual care and computer decision support strategies. This analysis suggests that even a modestly effective intervention to safely reduce antibiotic prescribing can be economically reasonable when implementation costs are low.

CT SCAN OVERUSE IN FREQUENTLY ADMITTED MEDICAL PATIENTS

Mina Owlia; Gregory M. Bump; Franziska Jovin; Christopher Deible; Marion Hughes; Lan Yu. University of Pittsburgh Medical Center-Oakland, Pittsburgh, PA. (Tracking ID #1903461)

BACKGROUND: Computed Tomography (CT) is an overused diagnostic tool. Clinicians may have limited understanding of how often CT scans lack clinically important findings. We describe the frequency of CT scan use in patients with frequent medical hospitalizations as well as the frequency of clinically important findings identified on these examinations.

METHODS: We retrospectively reviewed all CT scans done in 130 patients with greater than 7 admissions to medical services between January 1, 2011 and Dec 31, 2011 within an integrated health care system. We calculated the number of CT scans performed, the anatomic site of imaging, the source of ordering (emergency department, inpatient floor, or intensive care unit) and scored all CT scans using a

novel scoring system on a 0–4 scale based on the severity of radiographic findings. Higher scores signified more clinically important findings with a score of 0 representing a normal study, a score of 1 showing minimal abnormalities with no need for follow up, score of 2 showing minor abnormalities which likely require followup, a score of 3 showing major abnormalities likely to affect management, and a score of 4 representing a critical or emergent finding.

RESULTS: A total of 795 CT scans were performed with a mean of 6.7 ($\pm SD$ 5.8) CT scans per patient. Abdominal/Pelvis (39 %), chest (30 %), and head (22 %) CT scans were the most frequently obtained. The most common site of CT scan ordering (53.7 %) was the inpatient floors. Head CTs had the lowest rate of clinically

significant findings (4 %), compared to 38.3 % of chest CTs and 31.5 % of abdominal/pelvis CTs (Table 1).

CONCLUSIONS: Patients with frequent medical admissions undergo multiple CT scans that infrequently show findings that change clinical management. In particular, head CTs are rarely associated with significant findings and should be ordered less frequently. Inter-disciplinary measures should be advocated by hospitalists, emergency department physicians, and radiologists to decrease unnecessary imaging in this population.

Distribution and frequency of reconciled scan scores based on type of CT scan

Scan by modality	Mean # CT scan (SD) per patient	Median \$ CT scans per patient	Scores	0 (n=90)	1 (n=360)	2 (n=126)	3 (n=200)	4 (n=19)	Total N (%)
Head CT	2.9 +/- 4.2	1		64 (37.2)	95 (55.2)	6 (3.5)	3 (1.7)	4 (2.3)	172 (21..6)

CULTURAL COMPETENCE AND PERCEPTIONS OF COMMUNITY HEALTH WORKERS' EFFECTIVENESS FOR IMPROVING HYPERTENSION OUTCOMES AND REDUCING HEALTH DISPARITIES Meta Mobula¹; Mekam T. Okoye¹; L. Ebony Boulware²; Kathryn A. Carson^{1,3}; Jill A. Marsteller³; Lisa A. Cooper^{1,3}. ¹Johns Hopkins University School of Medicine, Baltimore, MD; ²Duke University School of Medicine, Durham, NC; ³Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (Tracking ID #1938515)

BACKGROUND: Community Health Worker (CHW) interventions improve hypertension control among ethnic minorities, but health professionals' perceptions of their effectiveness may impede integration of CHWs into health care delivery systems. Health professionals' cultural competency has also been identified as a potential strategy to improve health outcomes of patients from diverse social groups. We explored the association between provider and staff self-reported cultural competency and preparedness to deliver cross-cultural care with attitudes towards effectiveness of CHWs in reducing health care disparities and improving clinical outcomes.

METHODS: We administered a questionnaire to providers (physicians and nurse practitioners) and clinical staff (nurses, medical assistants and others) from six urban primary care practices in Maryland to assess their self-reported cultural competence; preparedness to deliver cross-cultural care; and perceptions of a proposed CHW intervention. Cultural competence was assessed in three domains: motivation to learn about other cultures, cultural behavior and power and assimilation. We quantified the associations of cultural competence and preparedness with attitudes towards the effectiveness of CHWs using logistic regression adjusting for respondent age, race, gender, provider/staff status and years at the practice.

RESULTS: We contacted 200 providers and clinical staff, and 119 (60 %) participated. Providers and staff reporting more cultural motivation had higher odds of perceiving CHWs as helpful for improving patient outcomes (OR=2.56, 95 % CI=1.32–4.96) and reducing health disparities (OR=10.05, 95 % CI=3.55–28.44). Those reporting more frequent culturally competent behaviors also had higher odds of believing CHWs would help improve patient outcomes (OR=1.96, 95 % CI=1.02–3.76) and reduce health disparities (OR=3.59, 95 % CI=1.62–7.99). Providers' attitudes towards power and assimilation for socially disadvantaged groups were not associated with their perceptions of CHWs. Cultural preparedness was associated with providers' perceived utility of CHWs in reducing health disparities (OR=2.32, 95 % CI=1.20–4.47), but not significantly associated with improving health outcomes (OR=1.72, 95 % CI=0.88–3.35).

CONCLUSIONS: Providers and staff with higher self-assessed cultural motivation, culturally competent behaviors, and cultural preparedness have more positive expectations of CHW interventions to reduce health disparities. The group that self-assesses as more culturally competent may know more about specific challenges faced by underserved patients and thus be more likely to see advantages of involving CHWs to overcome those challenges. Cultural competence training for providers and staff may complement the use of CHWs and support their effective integration into primary care clinics that are seeking to improve health outcomes and reduce disparities.

CULTURAL TAILORING OF STROKE RISK FACTOR REDUCTION AND WALKING PROMOTION COMMUNITY INTERVENTION FOR SOUTH ASIAN OLDER ADULT IMMIGRANTS Nazleen Bharmal¹; Brian S. Mittman²; Raina Shah³; Catherine Sarkisian^{2,1}. ¹UCLA, Los Angeles, CA; ²V.A. Greater Los Angeles Healthcare System, Los Angeles, CA; ³University of California, Irvine, Irvine, CA. (Tracking ID #1933529)

BACKGROUND: South Asians are people with origins from India, Pakistan, Bangladesh, Nepal, and Sri Lanka. They are among the fastest growing U.S. immigrant groups. Epidemiological studies in Western countries have documented disproportionately high prevalence and mortality rates of coronary heart disease and stroke, with much of the excess stroke mortality in South Asians attributed to physical inactivity. Our objectives were to culturally-tailor an existing stroke risk factor reduction/walking promotion intervention and assess the feasibility of implementing the proposed intervention in senior centers for South Asians.

METHODS: We used community-based participatory research (CBPR) and implementation science methods to collect and analyze data from a community advisory board (CAB), focus groups, and stakeholder interviews in an iterative fashion. Community partners included a South Asian community-based organization (CBO) and two senior centers located near ethnic enclaves of low-income, recently immigrated South Asians. The theoretically-grounded intervention curriculum was designed as part of a NIH/NINDS-funded RCT and incorporated elements of moderated small group discussions, scenarios, didactics, goal-setting and reflection over eight sessions. CAB members reviewed the initial curriculum and provided input on the curriculum approach, content, context, and language based on the ecological validity and community-based developmental models to cultural adaptation. Using CAB input on the curriculum, we conducted three focus groups of Hindi-speaking South Asian older adults to identify knowledge and awareness of stroke risk factors and barriers and facilitators to walking. Focus group audio recordings were translated into English and transcribed. Using content analysis, CAB members reviewed the focus group transcripts and generated themes of stroke awareness and walking beliefs, as well as potential curriculum modifications to address these beliefs. We also interviewed key stakeholders to identify general and site-specific factors associated with greater likely effectiveness of the proposed intervention.

RESULTS: During the initial review, CAB members recommended changes to the intervention curriculum to be better received by South Asian seniors (Table 1). The 33 focus group participants had a mean age of 72.8 years. Most were male (55 %), had at least a college degree from India (65 %), had lived in the U.S. for less than 20 years (56 %), and were mostly or very comfortable speaking English (58 %). Participants had been diagnosed with stroke (19 %), hypertension (64 %), and hyperlipidemia (44 %), and engaged in walking (67 %) or yoga (33 %) for physical activity. Themes identified by CAB members from the focus groups to address in the intervention are presented in Table 2. CAB members recommended having 15–20 min of group walking after each small group session. Stakeholder interviews confirmed enthusiasm from both senior centers as intervention sites, CBO interns as potential session moderators, and CBO willingness to provide resources for participant recruitment and follow-up. Two barriers identified were the diversity of South Asian languages

spoken by potential participants and participants' lack of experience in engaging in a long-term intervention, as opposed to a one-time workshop.

CONCLUSIONS: Community-based participatory approaches are effective ways to integrate evidence-based interventions that are systematically and culturally consistent into existing community infrastructure. We found this CBPR approach led to concrete and substantive input on content and delivery, while still allowing for the fidelity of the intervention. Our community-academic partnership resulted in interest about the topic of healthy aging, strong enthusiasm and leadership in shaping the culturally-tailored intervention, and excitement about its implementation by the community partners, CAB, and potential participants. Our next step will be to conduct a pilot intervention in one senior center with the goal of increasing walking steps and beliefs that physical activity is an important part of healthy aging that can reduce stroke risk.

Stroke Awareness	Walking Beliefs and Behaviors
<ul style="list-style-type: none"> • Need for more information as to the nature of stroke, why it occurs (genetic risk?), and what to do if someone is having a stroke • Stroke knowledge is gained from friends and family, as opposed to healthcare providers • Ayurvedic and alternative medicine play a role in stroke prevention and treatment 	<ul style="list-style-type: none"> • Walking groups that have a walking "leader" was suggested to increase opportunities for social network as most seniors felt socially isolated • Incentives should address social aspects of the activity, such as "chai" and biscuits at workshops or after walking • There appears to be two extremes: people who walk regularly versus those who are not physically active. This difference impacts walking acceptability and understanding benefits • Barriers included family obligations for childcare (grandchildren), not a priority, idea of "being selfish" is novel in culture, knee pain, weather. Housework commonly seen as a form of moderate physical activity. • Facilitators included personal stories of how walking prevented more severe disease and/or medical interventions

CURRENT PRACTICES AND OPPORTUNITIES IN A RESIDENT CLINIC REGARDING THE CARE OF OLDER ADULTS WITH MULTIMORBIDITY

Nancy Schoenborn; Cynthia M. Boyd; Matthew McNabney; Anushree Ray; Danelle Cayea. Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #1936991)

BACKGROUND: Multimorbidity (2 or more chronic conditions) is a common problem that affects more than half of all older adults. Multimorbidity is associated with higher mortality, disability, institutionalization, decreased quality of life, and higher rates of adverse effects from treatments or interventions. Guiding Principles for the care of older adults with multimorbidity were developed and published by the American Geriatrics Society. Clinicians report inadequate training in caring for older adults with multimorbidity but it is not clear what opportunities arise in clinical encounters to apply the Guiding Principles and how clinicians currently practice

regarding the Guiding Principles. Our study explores the current practices and opportunities for improvement in a resident clinic regarding the care of older adults with multimorbidity.

METHODS: In this qualitative study, we audio-recorded clinic visits between residents and patients who were ≥65 years old and with ≥2 chronic medical conditions in the General Internal Medicine resident clinic at Johns Hopkins Bayview Medical Center. We explored the resident-patient discussions related to the five domains of the Guiding Principles: Patient Preferences; Interpreting the Evidence; Prognosis; Clinical Feasibility; and Optimizing Therapies and Care Plan. The recordings were transcribed, coded and analyzed using the grounded theory approach, generating themes and sub-themes.

RESULTS: We have recorded visits between 17 residents (6 PGY1s, 6 PGY2s, 5 PGY3s) and 26 patients. Each resident had 1–4 recorded visits. Each patient was recorded once. Patients' mean age was 74.1 years, with on average 3.5 comorbidities, 12.7 medications, and mean self-rated health score of 68 on the EuroQol visual analog scale. All visits included discussions that were thematically related to the content of at least one of the Guiding Principles, most often Patient Preferences, Clinical Feasibility, and Optimizing Therapies and Care Plan; discussions related to the other two Guiding Principles were less frequent with very rare discussion related to Prognosis: a) The discussions related to Patient Preferences often included patients' opinions about decisions such as whether to pursue medication changes, procedures, or specialist referrals, but were not often associated with discussions about the expected benefits and harms of these decisions. b) Discussions related to Interpreting the Evidence occurred infrequently, and did not often include consideration of the applicability of the evidence in the context of multimorbidity. c) The discussions related to Clinical Feasibility often considered treatment complexity and feasibility in the context of medications compared to other treatment modalities. d) The discussions related to Optimizing Therapies and Care Plan more frequently involved specific diseases than the interactions among multiple conditions or their treatments. e) A number of opportunities to incorporate Guiding Principles as prompted by patients or patients' medical conditions were missed by residents.

CONCLUSIONS: During clinic visits with older patients with multimorbidity at a resident clinic, discussions related to some of the Guiding Principles occurred more frequently than others. Medical content of the visits and patient prompts provided regular opportunity to incorporate the Guiding Principles but were not always acted upon, suggesting room for improvement. We will implement an innovative curriculum to teach how to better incorporate elements of the Guiding Principles into clinical visits.

DANCE YOUR WAY TO BETTER HEALTH: EFFECTS OF TANGO DANCE ON MILD COGNITIVE IMPAIRMENT IN OLDEST OLD ADULTS

Teresa Ingram¹; Madeleine E. Hackney². ¹Emory, Atlanta, GA; ²Emory, Atlanta, GA. (Tracking ID #1941542)

BACKGROUND: With the baby boomer generation in the United States, our elderly population will increase exponentially over the course of the next 30 years. Many oldest-old adults have sensory, motor, and cognitive impairments leading to reduced independence and social isolation. Not only does cognitive impairment causes decline in quality of life, but it also increases morbidity and mortality risk and carries a huge burden on the healthcare economics. Our purpose is to determine the effects of a 12 week course of Tango-adapted dance classes vs. group educational sessions on the cognitive performance in an oldest-old adult population with Mild Cognitive Impairment (MCI).

METHODS: Participants were assigned to 20, 90-min lessons in Tango or Education that took place at six different senior independent living communities. Only one site offered Education; while tango was offered at the other sites. Participants were assessed on the following measures of cognition: Trail Making Test (TMT), with parts A and B, Montreal Cognitive Assessment (MoCA), Timed Up and Go Cognitive, and Brooks Spatial Memory Test prior to and after intervention. Errors and number correct were evaluated.

RESULTS: 74 participants enrolled in the original study (Tango, $n=52$; Education, $n=12$). For this analysis, criteria for exclusion included anyone under age 80 and completion of less than 5 education or dance sessions which yielded a study population of 41 (Tango, $n=32$, Education, $n=9$). Within the tango group, there was improvement in Timed Up and Go Cognitive scores (pre-intervention average 19.4, post-intervention average 18.1, change average score of 1.29; p -value 0.07). Timed Up and Go score alone did not improve significantly within the Dance group (change average of 0.75, p -value of 0.37). There was no significant improvement in Timed Up and Go Cognitive scores in the Education group. Alternatively, Brooks spatial scores improved significantly within the Education group (pre-intervention average 59.5, post-intervention average 70.8; p -value 0.007) compared to Dance group (p -value

0.05). There were no statistically significant differences with in MoCA or TMT scores with either intervention.

CONCLUSIONS: Although the Timed Up and Go Cognitive scores within the Dance therapy group were not statistically significant, an improvement within the dual tasking/cognitive portion was evidenced by non-improvement within the motor aspect of the test (Timed and Go). There may be a role for dance and/or exercise in helping to maintain or improve MCI in oldest old adults. It is unclear why there were no improvements within the MOCA or Trail Making Tests which are tests of executive functioning. Further investigation of benefits of educational classes on the effects of spatial memory will be studied. This study is unique because of the focus on adapted Tango as well as having a population group over the age of 80. Limitations include low power, especially in the education group, and significant dropout rate. Also participant knowledge of class assignment could lead to potential bias. Larger population studies that also look into the effect of co-morbidities on test performance is warranted.

DEATH AMONG PATIENTS HOSPITALIZED WITH PNEUMONIA; IMPLICATIONS FOR HOSPITAL OUTCOME MEASURES Mihaela S. Stefan^{1,3}; Michael B. Rothberg²; Randa Jaber¹; Jane Garb¹; Janice Fitzgerald¹; Peter K. Lindenauer^{1,3}. ¹Baystate Medical Center, Springfield, MA; ²Cleveland Clinic, Cleveland, OH; ³Tufts University School of Medicine, Boston, MA. (*Tracking ID #1936240*)

BACKGROUND: Risk-standardized mortality rates are used to assess the quality of care for patients hospitalized with pneumonia, and were recently added to Medicare's Value Based Purchasing. The measure includes patients regardless of advanced directives (unless the patient is already in hospice) and those with terminal illnesses for whom pneumonia may play only a minor role in their death. The objective of this study was to assess the proportion of patients included in the CMS pneumonia mortality measure for whom pneumonia was a major contributor to death. In addition, we compared the intensity of care during hospitalization including admission to intensive care unit (ICU) and ventilation management for patients for whom pneumonia was a major contributor to death and those for whom it was not.

METHODS: Retrospective, chart review of adults who died with a principal diagnosis of pneumonia between January 2008 and December 2012 in three hospitals in Western Massachusetts. Determination of pneumonia as a major or minor contributor in the patient death was assessed by two reviewers who used a standardized abstraction form. Results were compared and discussed until the agreement reached 100 % (for a total of 57 charts); thereafter charts were assessed independent by each reviewer. Pneumonia was considered to have been a minor determinant if at admission patient had advanced comorbidities which may have been the major contributor to death (e.g. metastatic cancer). Patients' characteristics, comorbidities, ventilation management and advance directives were collected and compared between the two groups of patients.

RESULTS: We included 204 pneumonia deaths from three hospitals; 169 from a large academic center and 35 from 2 community hospitals. For the first 30 charts reviewed, inter-rater k agreement coefficient was 0.35. Discrepancies between the reviewers were resolved through discussion; agreement then rose to a k of 0.63 for the next 12 cases and to a k of 1.0 for the next 15 cases. The median age of the study population was 78.5 years, 46 % were male, 98 % had at least one major co-morbidity and majority were white (87 %). During hospitalization, 24 % were intubated and 25 % died in the intensive care unit. Pneumonia was considered to have played a minor role in patients' death in 167 (80 %) cases. Overall, 51 % of cases had a do-not-resuscitate order (DNR) at admission and 25 % at the time of death. Of those who had their code status changed during hospitalization, the change to DNR or comfort care was made on the day of death in 41 % of the cases.. Compared with patients for whom pneumonia was a major reason to death, patients for whom pneumonia was a minor contributor to death were slightly younger, had more advanced comorbidities (100 % vs 86 %); were less likely to be admitted to ICU (28 % vs 42) and to be mechanically ventilated (22 % vs. 32 %); were less likely to have mechanical ventilator withdrawn before death (78 % vs. 92 %) and were more likely to expire on the medical ward (76 % vs. 53 %).

CONCLUSIONS: Only a small fraction of deaths included in the pneumonia mortality measure are the direct result of pneumonia. The majority of patients who die are frail elderly with advanced non-modifiable conditions, most of whom decide to forego aggressive care at some point during their admission. The deaths of these patients do not necessarily reflect the quality of pneumonia care received. Only half of these patients had DNR orders on admission, and many initially received aggressive care, suggesting opportunities for discussion of end of life care before hospitalization.

DECADE-LONG TRENDS IN MORTALITY AMONG PATIENTS WITH AND WITHOUT DIABETES AT AN ACADEMIC MEDICAL CENTER IN AN ERA OF IMPROVED GLYCEMIC CONTROL Neel M. Butala¹; Benjamin K. Johnson³; James F. Dziura^{3,1}; Janis E. Bozzo²; Silvio Inzucchi¹; Thomas Balcezak^{1,2}; Leora I. Horwitz^{1,2}. ¹Yale School of Medicine, New Haven, CT; ²Yale-New Haven Hospital, New Haven, CT; ³Yale Center for Analytic Sciences, New Haven, CT. (*Tracking ID #1937226*)

BACKGROUND: Given the increasing prevalence of diabetes, historically worse outcomes for patients with diabetes when hospitalized, and recent trends toward improving glycemic control in both inpatient and outpatient settings, it is important to understand whether the mortality risk of diabetes during hospitalization has changed over the last decade. The objective of this study was to determine 10-year trends in in-hospital mortality for patients with versus without diabetes and to examine the potential impact of inpatient and outpatient glucose control.

METHODS: We conducted a serial cross-sectional observational study of all adult non-obstetric patients with an inpatient admission between Jan 1, 2000 and Dec 31, 2010 at a major urban medical center. The primary exposure of interest was a diagnosis of diabetes mellitus and the main outcome was in-hospital mortality. Additionally, we looked at measures of inpatient glycemic control (percentage of days with glucose below 70, glucose above 299, and glucose between 70 and 179, and standard deviation of glucose measurements) and hemoglobin A1c, which served as a measure of outpatient glucose control and a proxy for severity of diabetes. We constructed multivariate logistic regression models including time from start of study until admission in years, whether an individual had diabetes, and the interaction between time and diabetes status as well as age, sex, race, payer, diagnosis and comorbidities while stratifying by whether the hospitalization included an intensive care unit (ICU) stay. We then restricted our sample to ICU patients with diabetes and determined the relation between the measures of glucose control and changes in mortality over time using logistic regression.

RESULTS: We included 322,938 patient admissions, of which 54,645 (16.9 %) were ICU patients. 76,758 patients (23.8 %) had diabetes: 26.3 % of ICU patients and 23.2 % of non-ICU patients. Among ICU patients with diabetes, measures of inpatient control were available for 91.5 % and hemoglobin A1c for 34.7 %. The overall mortality rate was 2.4 %, representing 2.7 % of patients with diabetes and 2.2 % of patients without diabetes. However, raw mortality for patients with diabetes decreased from 3.6 % in 2000 to 2.2 % in 2010 while mortality for patients without diabetes decreased from 2.4 to 2.3 % during this interval. Among ICU patients, the 7.8 % reduction in the odds of mortality in each successive year for patients with diabetes (OR=0.923; 95 % CI: 0.906, 0.940) was significantly greater than the 2.6 % yearly reduction for those without diabetes (OR=0.974; 0.963, 0.985; $p<0.001$ for interaction). However, among non-ICU patients, the 9.6 % reduction in odds of mortality for patients with diabetes (OR=0.904; 0.879, 0.929) was not significantly different from the 7.5 % reduction for those without diabetes (OR=0.925; 0.909, 0.940). Among ICU patients with diabetes, a significant decline in mortality persisted after adjustment for measures of inpatient and outpatient glucose control.

CONCLUSIONS: Patients with diabetes in the ICU have experienced a disproportionate reduction in in-hospital mortality that cannot be explained by the quality of inpatient or outpatient glucose control. While improved glycemic control may have other benefits, it does not appear to impact in-hospital mortality. Potential explanations for this interesting trend include improved cardiovascular risk management or advances in therapies for diseases that disproportionately affect diabetics (e.g. coronary stents).

DEEP VEIN THROMBOSIS BELOW THE KNEE: DO WE TREAT AND SHOULD WE TREAT? Anita Pudusseri; Raji Shameem; Robert E. Graham. Lenox Hill Hospital, New York, NY. (*Tracking ID #1910852*)

BACKGROUND: Below knee DVT is rarely associated with progression to pulmonary embolism (PE). However, patients often receive treatment with novel oral anti-coagulants, with a notable consequence of anti-coagulation being increased risk of bleeding. The current Guidelines for Anti-Thrombotic therapy from Chest 2012 (based upon observational studies and expert opinion) recommend that patients with acute isolated distal DVT of the leg and severe symptoms or risk factors for extension require initial anticoagulation over serial imaging of the deep veins.

METHODS: This was a retrospective review of patients that presented to a community hospital from June 1, 2012 to June 30, 2012 requiring a lower extremity venous doppler for any reason. Information was gathered using the Synapse database. The location of the DVT, which exact vein, the reason for the study, which department, whether the patient was treated and with what form of treatment were all collected. Patients already on anti-coagulation at the time of diagnosis were excluded,

including but not limited to atrial fibrillation, stroke prevention, pulmonary embolism, and acute coronary syndrome.

RESULTS: Forty-five patients with lower extremity DVT were included. Of the 45 patients, 28 patients were from the medicine department, 3 from orthopedics, 2 from cardiology and surgery, 1 from obstetrics and 9 from other departments. 80 % (36/45) of patients were treated with anti-coagulation for DVT. Most patients were treated with heparin to warfarin bridge (36 %; 13/36) or enoxaparin to warfarin bridge (42 %; 15/36). Five patients were treated with enoxaparin alone, one patient was treated with heparin to fondaparinux sodium bridge and three patients were treated with warfarin alone. Of the three patients that were not treated with anti-coagulation, one patient had a known DVT and had repeat ultrasound imaging. The other two patients had intramuscular vein thrombosis and thus were not treated. Two of the 45 patients had adverse events of clinically significant bleeding.

CONCLUSIONS: A large majority of our patients were treated with anti-coagulation for a below knee DVT despite the known low risk of progression to PE. Given this data we plan on conducting a prospective study examining the management of a new diagnosis of below knee DVT. One of the outcomes studied will be to determine the extension of DVTs over a period of time using serial imaging.

DEFICITS IN THE TRANSFER OF ADVANCE CARE PLANNING INFORMATION FOR PATIENTS DISCHARGED FROM HOSPITALS TO NURSING HOMES *Peggy Leung^{2,1}; Clarke Low¹; Anne M. Walling^{1,2}; Neil Wenger^{1,2}*

¹University of California, Los Angeles, Los Angeles, CA; ²David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA. (*Tracking ID #1939638*)

BACKGROUND: Prognostic discussions and decisions about aggressiveness of care made in the hospital are often lost when patients transition to nursing facilities. For patients with serious illness and particularly for those for whom decisions have been made not to use cardiopulmonary resuscitation (CPR) and other burdensome treatments, Physician Orders for Life-Sustaining Treatment (POLST) is a legal document that translates patient end-of-life treatment preferences into actionable medical orders that are preserved across venues of care. This tool is widely used in hospitals and nursing homes across California. We aimed to investigate how often patients with do not resuscitate (DNR) orders were discharged from the hospital to a nursing facility without adequate transmission of this information across facilities.

METHODS: We identified all adult discharges from two hospitals to a skilled nursing facility over a three month period in 2013. We developed a medical record abstraction instrument that identified a patient's resuscitation status during hospitalization and at discharge and whether this was communicated to the nursing home in the discharge summary and whether a POLST was completed. In cases where there was discrepancy between the resuscitation status at discharge and the information communicated, we explored the reasons for the difference.

RESULTS: Of 461 patient discharges (449 unique patients), 347 (75.3 %) patients were "full code" at time of transfer, 89 (19.3 %) patients had a DNR status at the time of transfer, and for 25 (5.4 %) patients there was no "code status" documented on transfer. Of the 347 patients who were full code, 65 (18.7 %) had a POLST indicating this at discharge. Of the 89 patients who had a DNR order at the time of transfer, 29 (32.7 %) had a valid POLST on transfer that contained this information. An additional 23 patients had POLST forms on transfer that were inconsistent with resuscitation decisions at discharge: 13 patients with a "full code" status had a POLST that indicated DNR, five patients with a DNR status on transfer had a POLST that indicated CPR, and five patients had POLST forms with other content inconsistent with decisions made on discharge.

CONCLUSIONS: At two hospitals in one health system, detailed evaluation of medical records for patients discharged to nursing homes demonstrated that even among patients for whom a DNR order was in place at time of transfer, less than one third had POLST documentation of this preference. In the studied hospitals, efforts are needed to improve the transition of resuscitation information from hospital to nursing home.

DEFINING APPROPRIATE USE OF ACID SUPPRESSION AMONG MEDICAL INPATIENTS *Matt Pappas¹; Sanjay Jolly²; Sandeep Vijan¹*. ¹University of Michigan Health System, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI. (*Tracking ID #1936603*)

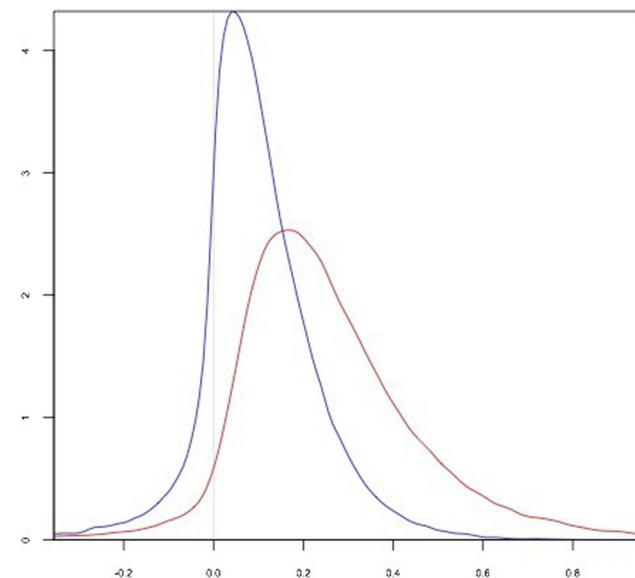

BACKGROUND: Proton pump inhibitors (PPIs) are commonly used among medical inpatients, with some studies suggesting that as many as half of all inpatients receive PPIs. Routine use of PPIs is common for symptom relief and, in higher risk patients, to reduce the risk of upper GI bleeding (UGIB). Recent evidence has suggested that

PPIs increase the risk of nosocomial infections, including healthcare associated pneumonia (HCAP) and Clostridium difficile infection (CDI). We sought to examine the balance between risks and benefits of PPI use among medical inpatients in various categories of risks of UGIB, HCAP, and CDI.

METHODS: We created a microsimulation model to estimate the risks of UGIB, HCAP, and CDI among medical inpatients. Risks of each of these conditions were generated using published risk models. We then modeled changes in risk associated with PPI use for each of these outcomes, basing our estimates on meta-analyses and observational studies. We examined the overall impact of PPI use on inpatient mortality, including both population level risk and individual thresholds at which PPI use would be beneficial (through reduction in UGIB risk) or harmful (through increases in HCAP and CDI). We examined several scenarios to account for heterogeneity in the strength of the evidence for the causal relationship between PPIs and our modeled outcomes, and conducted both one-way and multivariate sensitivity analyses (using second order Monte Carlo simulation) across all parameters in the model.

RESULTS: In our first scenario, where PPI use was causally linked with changes in risks of all three outcomes (UGIB, HCAP, and CDI), we found that PPI use led to an increase in mortality in over 95 % of hospitalized patients. In our second scenario, with no causal association between PPI use and CDI, we found that PPI use led to an increase in mortality in 86 % of hospitalized patients. Sensitivity analyses showed that even with a low odds ratio for HCAP, PPI use led to increased mortality in 91 % of cases (assuming a causal link with CDI) or 68 % of cases (no causal link with CDI). We then examined percentiles of probabilities for HCAP, CDI, and UGIB to see if we could identify particular cases where benefit from PPI use was likely. However, only at extremes of the distribution were we able to identify patients who may benefit. For example, we modeled a patient at the 10th percentile for probability of HCAP, case fatality of HCAP, risk of CDI, and case fatality of CDI, but at the 90th percentile risk of UGIB risk and fatality. In such a patient, PPIs were neutral, with benefit in about half of such patients and harm in the other half.

CONCLUSIONS: Our study suggests that for the vast majority of medical inpatients, use of PPIs likely leads to an increase in short-term mortality. Even in patients at particularly high risk of UGIB, only those at the very lowest risk of HCAP and CDI should be considered for prophylactic PPI use. Indeed, our estimates suggest that withholding PPI therapy should be considered for most patients upon admission, with the exception of those who are at very high risk of or are hospitalized for UGIB. There are several limitations to our analysis. First, we are reliant on published estimates of the effect of PPI on HCAP, CDI, and UGIB, and for some outcomes, particularly CDI, there remains some controversy on the causality of the observed association. Second, we did not model additional outcomes such as length of stay; however, given the balance of risks and benefits we found, this is more likely to accentuate than alter our finding that PPIs generally lead to harm. Finally, we did not model specific settings such as the ICU or surgical patients. Overall, our findings suggest that PPI use should be avoided in the vast majority of medical inpatients.

Density plot of change in mortality for 100,000 simulations of 100-patient cohorts, assuming increased risk of CDI with acid suppression (red) and no increased risk of CDI (blue).

DELAYS IN ENTERING ABNORMAL TEMPERATURES INTO THE ELECTRONIC MEDICAL RECORD Alvin Rajkomar; S. Ryan R. Greysen. University of California, San Francisco, San Francisco, CA. (*Tracking ID #1939063*)

BACKGROUND: Newly abnormal vital signs in hospitalized patients often spur additional diagnostic testing and treatment, like evaluation for sepsis in a patient with a fever. Delays between measuring and recording temperatures in the electronic medical record (EMR), functions often performed by nursing staff, can delay timely recognition of conditions like sepsis, especially as clinicians and electronic surveillance tools use EMR data for monitoring. We sought to characterize the frequency and duration of these delays of entering temperature data into the EMR.

METHODS: We identified all temperature readings from adult inpatients admitted to UCSF Medical Center from June 1, 2012 to Dec 5, 2013. For each temperature reading, the location of the patient and the identity of the nurse who took the temperature were obtained. The delay was calculated by the difference between the computer-generated timestamp when the temperature was entered into the EMR and the nurse-generated time of when the vital sign was physically taken. Fever was

defined as a temperature greater or equal to 100.4° Fahrenheit. We used descriptive statistics and t-tests to analyze trends in entering temperature values.

RESULTS: There were over 1.3 million temperature readings throughout the study period. The mean delay was 42.6 min for all readings (range: 0 to 720 min, standard deviation: 75.8 min). There were 66,434 readings with a fever, and the mean delay was statistically lower at 36.6 min ($p < 0.001$). Interestingly, the delay was higher for patients with a new versus a persistent fever: of the 19,619 readings of a new fever, defined as the prior recorded temperature being below 100.4, the mean entry time was 42.3 min. Of the 46,815 readings of a persistent fever, defined as the prior temperature also indicating a fever, the mean delay was lower at 34.2 min. The delay was not only different between different nursing units but also between different nurses within a unit (Figure 1).

CONCLUSIONS: The average delay between obtaining a temperature and entering it into the EMR is greater than 40 min for newly febrile patients, and there is significant variation in delays between nursing units and individual nurses. Hospitals must consider new ways to promote timely entry of data into the EMR if they hope to capitalize on the advent of new sensors and the promise of using big data for real-time electronic surveillance of hospitalized patients.

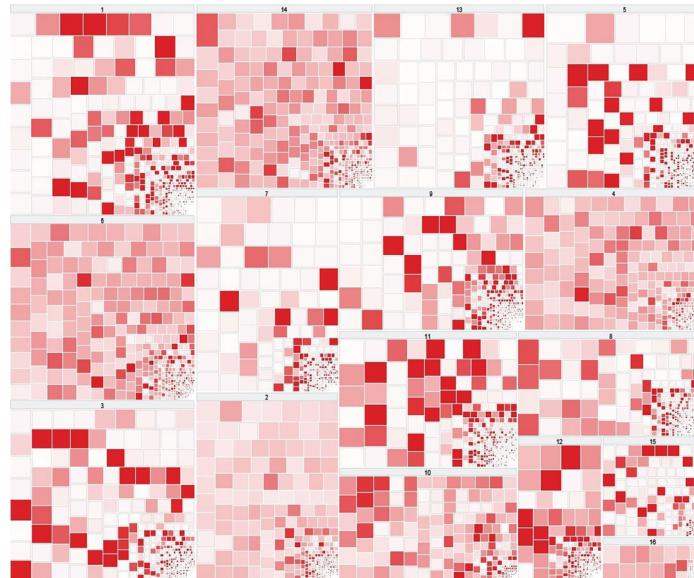

Figure 1: Median Delay in Entering Temperature into the EMR Each large, numbered rectangle represents a nursing unit, and every colored box represents an individual nurse within that unit. The color of the box is proportional to the median delay in entering temperature data into the EMR by that individual nurse. White indicates a median delay of zero minutes and red indicates a median delay of 60 min or more.

DELIVERING VIDEO PATIENT EDUCATION FROM THE EHR: PROMISES AND PITFALLS Shira N. Goldman¹; Tiffany Brown¹; Stephen D. Persell¹; Alpa Patel²; Crystal T. Doan¹; Kenzie A. Cameron¹. ¹Northwestern University, Chicago, IL; ²Northwestern Medical Faculty Foundation, Chicago, IL. (*Tracking ID #1926289*)

BACKGROUND: Alerts triggered by content in patients' electronic health records (EHR) are used regularly to prompt providers to improve the quality of care. These alerts can be leveraged to deliver educational content to specific patients at the point of care. We implemented an alert for licensed practical nurses (LPNs) and medical assistants (MAs), prompting them to show an educational video to patients eligible for pneumococcal vaccination (PnVx) while patients waited for their primary care provider (PCP) to enter the exam room. We report on lessons learned from this implementation.

METHODS: The PnVx educational video Best Practice Alert (BPA) was implemented in a large general internal medicine practice at an academic medical center using the Epic EHR. We designed and built the alert using a team of computer programmers, technical support specialists, and clinical and communication experts. We validated the decision rules to ensure the alert only triggered for patients eligible for PnVx who had no documentation of vaccination receipt or refusal in the EHR. PCPs provided consent for their patient panels to be included in this feasibility study. We trained LPNs and MAs to

launch the video from within the EHR when the alert appeared, and the PnVx BPA was then activated practice-wide. After 3 months, nurses were invited to participate in individual interviews and PCPs were sent a web-based survey. Patients were asked to participate in a telephone survey to assess their perceptions toward being shown a video at the point-of-care, as well as their thoughts on pneumonia, pneumococcal vaccination (on a Likert scale where 1 = Strongly Disagree and 5 = Strongly Agree).

RESULTS: We encountered technical barriers to successful implementation. These included hardware problems such as the need for uniform monitor resolution and lack of sound capability, and software problems, including failure of the video to function across multiple operating systems. Additionally, to retain the security of Epic and account for the fact that LPNs and MAs had varied workflows within the EHR, the BPA required several decision points, which corresponded to mouse clicks. Upon completion of patient intake, the LPN/MA would secure the patient's record and launch the video in an external browser. Despite these challenges, overall feedback to the alert was positive. Patients ($n=32$) perceived the video as easy to understand ($M=4.71$, $sd=0.81$) and informative ($M=4.46$, $sd=0.58$). PCPs ($n=30$) did not perceive a negative impact on their workflow, nor did they believe the addition of the alert and video delayed the rooming process. LPNs and MAs ($n=10$) had varying responses to the addition of this activity to their workflow; some perceived it to be a minor task benefitting patients, while others reported that it was overly complicated and bothersome.

CONCLUSIONS: At a site using multiple provider-directed alerts, implementing a clinical decision support-triggered patient education video identified unanticipated obstacles. While many of the technical challenges were surmountable, encouraging nurses to act on the alert remains challenging. Challenges include the fact that numerous steps are required to launch the video and the absence of a clinic-wide incentive or policy supporting this effort. Although many nurses responded positively, others did not perceive point-of-care patient education as essential for improving patient care. Further research is needed to determine the best ways to involve the

entire medical team in patient care and assess the impact of this point-of-care intervention on uptake of vaccination and other preventive health services.

DENTAL REFERRALS IN A FEDERALLY QUALIFIED HEALTH CENTER: THE LINK BETWEEN ORAL AND SYSTEMIC HEALTH Lanna Little; James F. Hanley; Garry Souffrant. University of Texas Health Science Center San Antonio, San Antonio, TX. (*Tracking ID #1939712*)

BACKGROUND: Oral health and systemic health are intricately connected. The Federally Qualified Health Centers (FQHCs) are uniquely positioned to treat both oral and systemic health as they provide comprehensive medical and dental care. The path for most patients to see the dentist is a referral from a primary care physician. Although the dental referral may be an important link between medical and dental health care, most physicians have little insight on how to optimize this process. Little research has been conducted to characterize the referral process and referral population.

METHODS: Chart review was performed, identifying 420 adult patients who have been seen in the past two years at the FQHC and have received a referral to the dentist. Comorbidities and demographics were recorded for each subject, as was information regarding the dental referral. Data was analyzed using SPSS.

RESULTS: The most common reason for referral was pain, which was cited in 58 % of referrals. In about 40 % of dental referral patients, some sort of dental emergency was reported (pain, abscessed tooth or loose tooth). About one third of patients indicated that seeking dental referral was their primary reason for coming to the clinic. Most patients received only the referral but no treatment by the physician. Only half saw the dentist and half of those were diagnosed with some degree of periodontal disease. Patients with acute complaints such as dental pain or abscess were more likely to see the dentist than those referred for diabetes mellitus. Out of everyone who sought dental referral, 10 % were subsequently screened for and diagnosed with a new condition (diabetes or dyslipidemia).

CONCLUSIONS: Although dental referrals were common in our FQHC and dental pathology was frequent, most physicians provided little treatment prior to the dental visit. Most physicians have both limited experiences and limited knowledge of the management of dental urgencies/emergencies. Implementation of inter-professional education in medical school or primary care residencies could equip physicians to treat the patient properly until they see a dentist, and could also facilitate the referral process. It may be appropriate for FQHCs to develop inter-professional guidelines for physicians and dentists concerning the management of these patients. While dental care is often considered discretionary, urgent dental problems significantly impact patients' quality of life and poor dental hygiene may impact management of many chronic diseases. Having periodontal disease treated may positively affect these patients' systemic health. This is especially important for patients with diabetes mellitus. Lastly, it is important to take dental pain patients seriously and use their visit as an opportunity to perform the indicated health screenings.

DEPRESSION IS ASSOCIATED WITH CLINICAL INERTIA IN MANAGEMENT OF HYPERTENSION IN THE PRIMARY CARE SETTING Nathalie Moise¹; Karina Davison^{1,2}; William Chaplin^{1,3}; Steven Shea^{1,4}; Ian M. Kronish¹.

¹Columbia University Medical Center, New York, NY; ²Columbia University Medical Center, New York, NY; ³St. John's University, Queens, NY; ⁴Columbia University, New York, NY. (*Tracking ID #1926816*)

BACKGROUND: Depression is a known risk factor for poor prognosis among patients with cardiovascular disease. Numerous biological and behavioral mechanisms have been proposed. However, few studies have investigated the association between depression and 'clinical inertia', or lack of treatment intensification in individuals not at evidence-based goals for care. To address this gap, we assessed whether a diagnosis of depression is associated with clinical inertia in patients with uncontrolled hypertension.

METHODS: A convenience sample of 28 attending primary care providers (PCP) and 158 patients with uncontrolled hypertension was enrolled from two inner-city, academic-hospital based clinics. Eligibility criteria were age ≥ 18 years, prescribed ≥ 1 blood pressure (BP) medications, and BP $\geq 140/90$ mmHg (or $\geq 130/80$ mmHg if diabetic or with chronic kidney disease) on at least two consecutive scheduled visits with one's PCP. Clinical inertia was defined as lack of (1) medication intensification (2) specialist referral or (3) secondary hypertension work-up. Depression diagnosis was based on PCP documentation in the electronic chart. Multilevel modeling accounting for clustering of participants within PCP was conducted to assess the risk of clinical inertia in depressed patients while adjusting for known predictors of clinical inertia. Sensitivity analyses were performed that (1) excluded visits with

documentation of at least one controlled clinic or home BP (2) accounted for medication adherence counseling by PCP and (3) excluded diabetics with systolic BP (SBP) ≤ 140 mmHg.

RESULTS: The mean age (SD) of patients was 64.5 (8.8) years; 74.1 % were women, 79.1 % were Hispanic, 44.9 % was diagnosed with depression and 61.2 % had diabetes. On average, participants had a prior visit SBP of 158.7 (15.7) mmHg, current visit SBP of 154.6 (16.7) mmHg, were taking 2.5 (1.1) BP medications and had 5.3 (2.3) problems addressed during the visit. Clinical inertia was more common amongst depressed than non-depressed patients (70 % vs. 51 %; $p=0.015$). Depression diagnosis was associated with clinical inertia in both the adjusted and unadjusted multilevel analyses (RR=1.40; 95%CI, 1.11–1.74; $p=0.004$; adjusted relative risk [ARR]=1.49; 95%CI, 1.06–2.10; $p=0.021$). The relationship remained after excluding those with at least one documented home or clinic visit SBP below goal (ARR=1.74; 95%CI, 1.07–2.83; $p=0.025$), adjusting for adherence counseling (ARR=1.49; 95 % CI, 1.10–2.04; $p=0.010$) and excluding diabetics with SBP ≤ 140 mmHg (ARR=1.49; 95 % CI, 0.99–2.23 $p=0.057$).

CONCLUSIONS: Amongst patients with uncontrolled hypertension, clinical inertia was more likely in those with a diagnosis of depression; this may be one mechanism by which depressed patients have worse cardiovascular outcomes. Research has shown that patients with mental illness receive less intensive medical care, such as coronary revascularization; our study extends this literature by demonstrating differences in clinician behavior with respect to cardiovascular risk factor management in this population. Future studies should explore underlying processes affecting clinician treatment practices. In the meantime, PCPs should be cautious about undertreating cardiovascular risk factors among patients identified as having depression.

DERIVATION OF ICD-10 CODE LISTS FOR NOVEL PATIENT SAFETY INDICATORS William A. Ghali; Danielle Southern; Hude Quan. University of Calgary, Calgary, AB, Canada. (*Tracking ID #1896442*)

BACKGROUND: Health data coded using the International Classification of Diseases have been widely used to identify the occurrence of adverse events that may be linked to suboptimal safety and quality of care. Some countries record 'diagnosis timing indicators', which allow data users to distinguish whether a coded diagnosis or event was present at time of admission as opposed to one that occurred after admission. Using this diagnosis-timing data element, we undertook a multistep process to produce novel patient safety indicators (PSIs).

METHODS: We queried 2,416,413 records in the Canadian national Discharge Abstract Database (DAD) for April 1, 2009 through March 31, 2010. All listed diagnosis codes were compiled, and 2,613 unique diagnoses were found to have a type '2' diagnosis designation, indicating that the diagnosis was not present at time of admission and thus arose after admission. Next, we asked an international panel of experts in patient safety and quality of care to participate in a Modified Delphi review process in which they undertook a two-phase review of all of the identified codes, to determine (using a 9-point scale) the subset of post-admission diagnoses that are highly likely to have a strong link quality of care and/or patient safety. The subset of identified codes were then grouped into clinically-related subgroups, and the frequency of events was determined in a database of all hospitalizations records from the province of Alberta, Canada.

RESULTS: Of the 2,613 diagnosis codes recorded at least once in Canadian data as a diagnosis arising after admission, 640 codes were judged by the expert panel to have a strong link to quality of care and patient safety. These codes were then reviewed by a second group of experts in patient safety to create summary PSI code groupings. These included: a single global PSI for 'any adverse event'; a smaller grouping of codes for 'serious adverse event threatening to life or vital organs'; and then a number ($n=17$) of other specific code groupings for specific types of events such as 'cardiac complications', 'respiratory complications', 'hospital-acquired infections', and 'venous thromboembolic events'. The annual event rates in Alberta provincial data for the global PSI of 'any adverse event' ranged from 4.5 % in 2005 to 5.6 % in 2011. The event rate for the 'serious adverse event' indicator was 0.8 %. The event rates for the other specific indicators ranged from a high of 2.0 % for 'Hemorrhagic Events' to a low of 0.03 % for the 'obstetrical complications affecting fetus' PSI.

CONCLUSIONS: The methodological work presented here utilizes the unique potential of diagnosis-timing indicators to produce a clinically-relevant listing of diagnosis codes that can be used to create novel PSIs that overcome some of the shortcomings of existing PSI systems. The resulting work has great potential to inform future approaches to health system monitoring, adverse event surveillance, and quality/safety improvement.

DESCRIBING THE STRUCTURE AND PATTERNS IN THE PHYSICIAN-PATIENT INTERACTION Harry B. Burke¹; Dorothy Becher¹; Patrick G. O'Malley¹; Jeffrey L. Jackson²; Ronald W. Gimbel¹. ¹Uniformed Services University of the Health Sciences, Bethesda, MD; ²Zablocki VAMC, Milwaukee, WI. (*Tracking ID #1937588*)

BACKGROUND: Although there is an extensive literature describing the semantics of physician-patient interactions, i.e., judgments regarding the meaning of participants' words and individual utterances, little is known about the interactional structures that constitute the physician-patient encounter. Structural units are the categories of verbal interactions that the participants use to achieve their goals (categories are described below). We hypothesized that these structural units would occur in a systematic manner across interactions.

METHODS: The unit of analysis was not the word or the utterance; it was the structural unit. Twenty audio-recorded established (rather than new) patient primary care outpatient physician-patient interactions were coded into structural units in terms of their interactional categories. A structural unit is composed of adjacent sequential utterances of the physician and patient that, taken together, meet one of the eight defined structural categories. The same type of structural unit could occur at various times throughout the interaction and at each occurrence the unit was coded and its location noted. Eight categories of interactional units were sufficient to describe the interactions: NEW, discussing a new medical problem; EXT, discussing an existing medical problem; WEL, discussing wellness and screening; REV, reviewing what had happened to the patient since the last visit including labs and medications; ADM performing administrative tasks such as ordering tests and prescriptions and filling our forms; SUM, summarizing the interaction; AGR, participant agreement; and SOC, discussing social topics.

RESULTS: We coded all pairs of adjacent units. There were 462 pairs across the 20 interactions. The inter-rater category agreement was 94 %. For most pairs we set a threshold of occurrence at 10 %. This analysis focused on the NEW and EXT units. The table below shows the relative frequency of the adjacent unit pairs. Relative frequency is the pair frequency divided by the overall frequency of the target unit. In terms of all the interactional pairs, NEW occurred in 10 % and EXT occurred in 27 % of the pairs. The arrow designates the order of occurrence of the adjacent units. PRIOR TO NEW.....Relative freq.....SUBSEQUENT TO NEW.....Relative freq.
 NEW⇒NEW.....0.06.....NEW⇒NEW.....0.06
 EXT⇒NEW.....0.15.....NEW⇒EXT.....0.29
 REV⇒NEW.....0.33.....NEW⇒EXT.....0.29
 ADM⇒NEW.....0.10.....NEW⇒ADM.....0.08
 SOC⇒NEW.....0.21.....NEW⇒SOC.....0.20
 PRIOR TO EXT.....Relative freq.....SUBSEQUENT TO EXT.....Relative freq NEW⇒EXT.....0.11.....EXT⇒NEW.....0.06
 EXT⇒EXT.....0.34.....EXT⇒EXT.....0.34
 REV⇒EXT.....0.21.....EXT⇒REV.....0.21
 ADM⇒EXT.....0.16.....EXT⇒ADM.....0.23
 SOC⇒EXT.....0.14.....EXT⇒SPC.....0.10

It was rare for a new medical problem to be adjacent to a new medical problem (NEW⇒NEW=0.06), but common for an existing medical problem to be adjacent to an existing medical problem (EXT⇒EXT=0.34). Reviews (REV) occurred with the same frequency before and after new problems (NEW), 33 %, 29 % and existing problems (EXT), 21 %, 21 %. Likewise, social topics (SOC) occurred with the same frequency before and after new problems (NEW), 21 %, 20 % and existing problems (EXT), 14 %, 10 %. There was an inverse relationship between new and existing problems in terms of the occurrence of adjacent reviews and social topics.

CONCLUSIONS: Structural units can describe physician-patient interactions. They appear to occur in a systematic manner and they can assist us in understanding of how physicians and patients interact to achieve their goals for the interaction.

DETERMINANTS OF HOSPITAL READMISSIONS AMONG LOW INCOME AND MINORITY OLDER ADULTS Ugochi K. Ohuabunwa^{1,2}; Jonathan Flacker^{1,2}; Queenie E. Jordan². ¹Emory University, Atlanta, GA; ²Grady Hospital, Atlanta, GA. (*Tracking ID #1942171*)

BACKGROUND: Low income and minority seniors constitute a vulnerable group during care transitions. Determinants of failure in transitions of care and rehospitalization in minority and low income populations have not been well defined. Understanding these determinants and consideration of the specific needs of this group of patients is essential in designing a transitional care model that will be effective in this patient population.

METHODS: We evaluated Medicare beneficiaries who were frequently hospitalized at our 953 bed safety net hospital from January to December 2010 by secondary data analysis of hospital administrative data to determine risk factors associated with repeated hospitalizations.

RESULTS: A total of 3790 patients were admitted during this period accounting for 4933 admissions. We classified all patients ($n=189$) admitted 2 or more times in a 6 month period as high risk. Our unadjusted all cause readmission rate was 25 %. Factors found to be significantly associated with readmission were female gender (60 %), African American race (94 %), age >75 year, patients residing in the Zip Code areas 30318, 30310 and 30311. The most common presenting diagnoses were congestive heart failure, psychoses, chronic obstructive pulmonary disease, septicemia and renal failure.

CONCLUSIONS: Definition of these determinants will form a basis for further needs assessment and the design of a transitional care model that will be effective in this patient population.

DETERMINING THE ACADEMIC HOSPITALIST SAFE CENSUS: RESULTS FROM A PHYSICIAN SURVEY AND HOSPITALIST SERVICE ANALYSIS Amy Baughman^{2,1}; Warren Chuang¹; Denisa Gace¹; Daniel P. Hunt¹. ¹Massachusetts General Hospital, Boston, MA; ²Brigham and Women's Hospital, Boston, MA. (*Tracking ID #1940088*)

BACKGROUND: Finding the appropriate patient-to-physician ratio is critical for optimizing patient care and physician satisfaction and productivity. Current literature in this area to guide hospitalist models of care is limited. However, it is well established that excessive patient responsibilities and work load can result in worse patient outcomes as well as increased physician burnout and dissatisfaction. Our hospitalist group has grown considerably which enabled our group to study the impact of higher census. In 2009, our service cared for 22 to 68 patients each day; by 2012, we cared for 54 to 127 patients. Despite hiring more staff, the individual physician census also increased. This challenged even our most experienced hospitalists to round on patients and complete discharges and admissions within their twelve-hour shift. When establishing a safe census, programs must consider regionalization of patients, ancillary staff or resident availability, case-mix index and physician characteristics. On our non-regionalized service, an individual hospitalist cares for patients scattered across several floors and buildings. On our regionalized service, however, the complexity of patients is higher. All of our physicians work without ancillary staff such as nurse practitioners or residents and significant physician time is required for administrative tasks, consultant and patient communication, and EHR documentation. Our goal was to determine how many patients a hospitalist physician at a tertiary academic medical center can safely care for during a typical 12 h shift.

METHODS: We describe a survey based method for identifying an optimal and safe census among hospitalists at our tertiary academic medical center. This assessment occurred in 2012 as a quality improvement initiative to gather feedback in several areas including optimal work flow and physician satisfaction. We also separately analyzed the impact of physician census on in-patient quality metrics including hospital readmission rates, length of stay and pre-noon discharges from 2010 to 2013. We then evaluated whether results from the physician survey were consistent with our quality metric outcomes.

RESULTS: Survey results showed that patient census was the most important factor contributing to physician satisfaction ($n=35$, Response Rate = 85 %). In that year, daily physician census varied from a low of six to a high of 14. We found that 92 % of physicians felt that the ideal patient-to-physician ratio was 10 or less for providing the highest quality of care. For half of physicians, the maximum patient number for safe care was 12; however the other half reported lower values of 10 or 11 patients. We reviewed monthly readmission rates, length of stay and pre-noon discharge rates from 2010 to 2013 for our hospitalist group. During this time, the monthly physician census ranged from 8.6 to 11.8 patients. We found that the readmission rate was slightly higher when the physician census was more than 11 (P value<0.05). Average length of stay and the percentage of pre-noon discharges did not change significantly with higher physician census.

CONCLUSIONS: Surveying physicians is a simple and effective method for identifying safe patient-to-physician ratios. For hospitalists at large tertiary medical centers with similar patient complexity, a safe census of ten is ideal for providing the highest quality of in-patient care. Evaluation of readmission rates, a crude measure of quality, supported this finding as readmission rates increased when census increased to more than 11.

DEVELOPING PATIENT-CENTERED DEFINITIONS AND RATINGS OF ENABLING SERVICES Robin Clarke¹; Anne Escaron¹; Rosy Chang Weir²; Petra Stanton³. ¹University of California, Los Angeles, Los Angeles, CA; ²Association of Asian Pacific Community Health Organizations, Oakland, CA; ³California Primary Care Association, Sacramento, CA. (*Tracking ID #1938362*)

BACKGROUND: Community Health Centers (CHCs) are safety net practices that have a long history of delivering non-medical or "enabling" services intended to reduce the social barriers to care faced by their low-income patients. Enabling services include providing transportation, performing community outreach, and delivering case management. The implementation of the Affordable Care Act offers new opportunities to

reimburse these patient-centered services, but limited evidence exists to guide CHCs and other providers in deploying effective services. We sought to begin to address this evidence gap by developing a research framework for analyzing this field of health care services and by starting the initial evaluation of these services.

METHODS: We adapted the RAND/UCLA modified Delphi method typically used to assess appropriateness of medical interventions. Using a community-partnered research team, we had three phases to our project. In the first phase, we used a literature review and an in-person meeting of 17 CHC patients and providers to define broad categories of services, discrete enabling services, and the variable levels of intensity by which a service can be delivered. An example of an intensity variable is: Health education delivered by a licensed personnel vs. by a non-licensed community member. In the second phase, we convened an expert panel composed of 13 CHC patients, providers, community patient advocates, and policy-makers. This panel used the validated RAND/UCLA 1–9 scale and iterative rounds of ratings to rate each enabling service as ineffective, equivocally effective, or effective. Effectiveness was defined as the degree by which a service increases a patient's access to, use of, and understanding of his or her medical care. In the last phase, we analyzed the ratings to identify the panel's recommendations by calculating each service's median effectiveness rating and the level of agreement or disagreement amongst the panelists. We used a Friedman test and a subsequent Wilcoxon Signed Rank test to determine whether effectiveness varied based on level of intensity.

RESULTS: The literature search identified 40 peer-reviewed articles that tested the effectiveness of enabling services. Based on these articles and their own knowledge, the patients and providers in the first group defined six categories: health education & supportive counseling; case management; outreach; interpretation; transportation; and financial counseling & eligibility assistance. Within these categories, 112 unique services were described, of which the expert panel elected to rate 77. Each of these services had between 1 and 4 levels of intensity at which it could be delivered resulting in a total of 181 unique service-variable combinations being rated by the expert panel. Health education & supportive counseling had the lowest median effectiveness rating as a category at 6.6 (out of 9) and outreach the highest at 7.5. Within each category, we identified the services that had a median effectiveness of 8–9 (or 9 for outreach) as the most highly recommended services. Twenty-four services across all categories met this threshold. Lastly, we found that the variable level of intensity had a significant effect on a service's rated level of effectiveness for some but not all services. For example, licensed professionals were rated significantly higher for developing care plans, whereas community health workers were equally effective in executing that care plan.

CONCLUSIONS: Because of their heterogeneity and the difficulty testing them against clear outcomes, enabling services make up a relatively understudied field of healthcare. In this study, our community-academic research team brought together two patient and stakeholder panels to define three constructs – six broad categories, 112 granular-level services, and various service intensity variables—as a framework for evaluating the effectiveness of these services. While not exhaustive, this list can serve as an important, initial classification scheme to guide further research. For providers and policy-makers, the list of most highly recommended services is the first report of its kind to provide guidance about priority services based on the perspectives of underserved patients and their representatives. In addition, by rating at the level of the service intensity, we identified opportunities to target resources to services where they are most needed to improve effectiveness. In many cases, the highest level of intensity did not necessarily increase perceived effectiveness. This study was limited by the dearth of literature suitable for the expert panel and the small number of experts used to create the recommendations. Nevertheless, given the potential that enabling services have for reducing social barriers to care, the categorization and ratings developed by this study provide a useful framework for further studying these services.

DEVELOPMENT AND APPLICATION OF A CLASSIFICATION SCHEME FOR CARE COORDINATION ACTIVITIES IN AN ACADEMIC PRIMARY CARE SYSTEM Nazleen Bharmal¹; Robin Clarke¹; Paul Di Capua¹; Indu Gupta¹; Brian Doyle¹; Aliza Ali²; Asad Malim³; Brian S. Mittman^{4,5}. ¹UCLA, Los Angeles, CA; ²Lake Erie College of Osteopathic Medicine, Bradenton, FL; ³College of Science and Health, Charles R. Drew University, Los Angeles, CA; ⁴VA Greater Los Angeles Healthcare System, Los Angeles, CA; ⁵Kaiser Permanente Southern California, Los Angeles, CA. (Tracking ID #1939165)

BACKGROUND: Primary care redesign aims to improve patient experience, improve health, and reduce costs. One opportunity to transform practice care delivery is to introduce supports to enhance primary care team effectiveness. In the field of care coordination, the RN-based case manager model is defined and well-understood; care managers may have a specific group of patients with chronic conditions for whom they develop individualized care plans and/or train in self-management skills. However, one of the limitations of the limited-panel, high-utilizer care manager model is that it may only touch on a small percentage of patients. In our large health system comprised of 28 primary care clinics throughout Los Angeles County, we embedded non-licensed care coordinators (CC) into clinics to integrate with primary care teams.

CCs would act as PCP extenders, assess patients' care needs, coordinate patients' care with other providers and settings, and connect patients to community resources and social services. To better describe and ultimately analyze the role of CCs in our health system, we developed and applied a classification scheme to categorize CC activities.

METHODS: The first five general internal medicine practices to incorporate a CC were included in the study. CC encounters were defined as any activity performed by a CC that (a) contributed to the development and/or implementation of a plan of care for a patient or family and (b) was documented by the CC in an online Patient Care Coordination System (PCCS) database established to track CC activities. A classification scheme to broadly categorize CC activities was developed iteratively by adapting models cited in a systematic review of care coordination published by the Agency for Healthcare Research & Quality (AHRQ) plus literature on case management, discussions with CCs, and our exploratory review of the PCCS database. Five coders, in total, coded all activities with high inter-rater reliability (kappa 0.89).

RESULTS: The five selected practices represented a diverse group of community and academic practices focused on family medicine, internal medicine, or geriatrics. The PCCS database contained 8,036 CC encounter records entered from June 2012 to July 2013 among the five primary care practices. Our 5-category classification scheme is presented in the table. The proportion of CC activities coded in each category was 38 % for execution of care, 32 % for coordination of transitions, 15 % for link to community resources or self-management support, 10 % for monitor and follow-up, 1 % for patient assessment, and 5 % for no classifiable activity.

CONCLUSIONS: CC documented activities provided evidence to the broad range of potential impact this model can have on patients, including helping patients navigate the health system, improving access and communicating across the care spectrum. CC activities are a vital part of helping primary care practices deliver coordinated, accessible, comprehensive, and patient-centered care; a valid and reliable classification scheme for these activities is an important tool for research and practice. The scheme we developed will be incorporated into CC training and a revised PCCS database and documentation system. The scheme will also facilitate subsequent phases of our research, including an assessment of the impact of CC activities and the degree of CC integration into primary care practices on key outcomes, including patient and provider satisfaction, chronic disease prevention and management, and preventable emergency room utilization.

Care Coordinator Activities by Mutually Exclusive Process Categories

Category	Definition	Examples of Activities
Execution of Care	Executing specific task delegated by PCP or requested by patient/family (with PCP approval) to meet a patient's needs	<ul style="list-style-type: none"> • Medication refills • Appointment scheduling • Authorization and/or referrals (e.g., specialists, tests, IV meds, DME) • Visiting nurse or home health coordination • Administrative—fax documents (e.g., FMLA, DMV, disability), provider or insurance changes
Coordination of Transitions	Managing patient follow-up after a hospitalization or ED visit	<ul style="list-style-type: none"> Schedule post-hospitalization or ED discharge patient for PCP visit within 48 h • Coordination of referrals and/or tests to be performed post discharge
Link to Community Resources or Self-Management Support	Providing patients with resources outside a clinical environment to assist with medical conditions	<ul style="list-style-type: none"> Patient education on urgent care evening hours • Housing/facility placement (e.g., hospice) • Caregiver support • Transportation resources • Benefit eligibility and financing of medications
Monitor and Follow-up	Checking in with patients to ensure proper follow through with medical tasks and maintaining patient-provider communication between clinic visits	<ul style="list-style-type: none"> Scheduling wellness checks • Notification to PCP and scheduling patients for P4P measures • Triage patient questions to PCP between visits
Patient Assessment	Helping to gather medical information and categorize high-risk patients before PCP visit	<ul style="list-style-type: none"> Referring patients who have high ED utilization to high-risk case management
No Activity	Any activity no classifiable under other categories	<ul style="list-style-type: none"> Attempted to contact patient; unable to leave message

DEVELOPMENT AND EVALUATION OF A PATIENT EMPOWERMENT LETTER IN A PRIMARY CARE SETTING Dan Matlock; Eva M. Aagaard; Adam Abraham; Wagner J. Schorr-Ratzlaff; Nivedita D. Mahidhara; Scott De La Cruz; Lisa Schilling; Brandon Combs; Carmen L. Lewis. University of Colorado, Aurora, CO. (*Tracking ID #1939663*)

BACKGROUND: Patients often feel disempowered when talking with their physicians. One study noted that patients feared questioning their doctors because they might be dismissed or labeled “difficult.” As part of the Patient Centered Medical Home (PCMH) initiative at the University of Colorado, we developed a letter to be given to patients prior to their clinic appointment to both empower patients and to help them set an agenda. Herein, we describe the development and evaluation of this letter.

METHODS: Development phase: Initially, the idea was to give patients something prior to their visit where they could write down their agenda. The letter was developed iteratively and piloted with patients. Ultimately, it included language designed to empower patients with phrases like “Please don’t feel that we will be upset if you have more questions.” The letter also included several lines for patients to write their “main goals, fears, and worries for the visit that day.” Evaluation phase: All adult patients aged 18–99 seen on one team at an internal medicine clinic over a two-week time period were included. The letter was evaluated using a pre-post design with the first week being the control and the second week including the letter. The primary outcomes were patient empowerment using the low-literacy version of the validated patient activation measure (13 items, 4 point Likert scale, scored 0–100) and patient satisfaction using the hospital mandated patient satisfaction measure (10 items, 5 point Likert scale, scored 0–5). Patients were also given the opportunity to provide open-ended feedback on the letter. Differences between mean scores were tested using t-tests.

RESULTS: We received a total of 171 responses (85 in week one and 86 in week two) from 248 distributed surveys (response rate=69 %). The sample was 63 % female, 39 % under the age of 55, 37 % had more than 4-year college degree, 76 % Caucasian and 56 % married. There was no difference in the Patient Activation scores between the control and intervention periods (71.4 vs. 68.9/100, $p=0.31$). There was a small but statistically significant decrease in satisfaction scores between the control and intervention (4.86 vs. 4.56/5, $p<0.01$) and overall satisfaction was very high. Patients had positive things to say about the survey: “Great letter and very impressive that your office is distributing this and indicating the need that every patient should be proactive with their own health and healthcare.” Suggestions on improving the letter including: arranging the key points into a bulleted list, shortening the overall length of the letter (simplifying) and including goals of care in patient print-outs.

CONCLUSIONS: Overall, the letter had no effect on patient activation and there was a small but significant decrease in patient satisfaction scores although overall satisfaction scores were very high. It is possible that satisfaction scores lowered slightly because patients’ agenda written on the letter were not addressed. Overall, the qualitative feedback suggests that the letter was well-received. We are currently working on a shorter version of the letter based on the results of this study.

DEVELOPMENT AND VALIDATION OF THE MEDICAL PROFESSIONALISM BEHAVIOR ASSESSMENT TOOL Preston Reynolds¹; James Martindale².

¹University of Virginia, Charlottesville, VA; ²University of Virginia, Charlottesville, VA. (*Tracking ID #1940065*)

BACKGROUND: Assessment of professionalism behaviors has become a priority with launching of the Milestones Initiative by the Accreditation Council on Graduate Medical Education. The Medical Professionalism Behavior Tool (MPB) was developed by P Reynolds with input from clinician-educators, education researchers, and internal medicine residents beginning in 2008. It is modified from the NBME’s Assessing Professional Behaviors tool with inclusion of behaviors relevant to cultural competency.

METHODS: As part of an annual internal medicine resident seminar series, P Reynolds began introducing the concept of evaluating professional behaviors in 2008. In subsequent years, she reviewed with the residents various behaviors and then a 25-item evaluation tool she developed modified from the NBME’s APB with inclusion of behaviors specific to cultural competency. Based on their feedback, the tool was reduced to 15 items with retention of the cultural competency skills. The MPB was then used by all of the medicine residents in three subsequent annual seminars as part of a self-reflective exercise where they were asked to rate themselves and then discuss with another resident one or two areas they specifically identified as needing improvement. These data were entered into a spreadsheet making the responses anonymous, and then subjected to statistical analysis to determine the degree to which evidence of reliability and validity was present in the MPB as an assessment tool. The MPB was also reviewed by 11 of 13 residency program directors at the University of Virginia for content validity.

RESULTS: All of the residency program directors thought the MPB captured behaviors relevant to evaluation of professionalism in clinical medicine. Statistical

analysis of the internal consistency (reliability) and construct validity associated with the MPB yielded strong results with Cronbach’s alpha = 0.84 and thus providing good statistical evidence of reliability and validity.

CONCLUSIONS: The strength of the MPB is that it is only 15-items, reflects behaviors central to medical professionalism as described in The Physician Charter, and also incorporates behaviors specific to culturally competent clinical care. Fourteen states now require demonstration of cultural competency as part of medical licensure making the MPB an important assessment tool to shape residency training to include skills training in medical professionalism, and in cultural competency. Additionally, the MPB is a tool that is reliable and valid and thus, can be used in formative and summative assessment.

DEVELOPMENT OF A SCREENING TOOL FOR IDENTIFYING HOUSING-RELATED BARRIERS TO CARE AMONG LOW-INCOME WOMEN Ambili Ramachandran¹; Samantha Morton²; Naomi Y. Ko³; Kerrie Nelson⁴; Maria Castano³; Emily Bergling³; Sharon Bak³; Jennifer Cedar³; Wanda Turner³; Tracy A. Battaglia³.

¹Boston University School of Medicine, Boston, MA; ²Medical-Legal Partnership | Boston, Boston, MA; ³Boston University School of Medicine, Boston, MA; ⁴Boston University School of Public Health, Boston, MA. (*Tracking ID #1934188*)

BACKGROUND: Social determinants of health include access to safe, healthy, and affordable housing. Support services such as patient navigation frequently target and resolve this barrier to care, but vulnerable patients sometimes need legal advice or advocacy to address these housing issues. It is often difficult in a health care setting to appropriately and efficiently determine which patients have housing problems that require legal advice or assistance. We developed a screening tool for use by patient navigators to identify individuals who would benefit from legal advice or assistance regarding housing-related barriers to care.

METHODS: The screening tool was designed in collaboration with Medical-Legal Partnership | Boston (MLP | Boston) and featured questions regarding utility expenses, mortgage and rent payments, foreclosures and evictions, and housing conditions. Dichotomous responses were designated “positive” or “negative” based on current Massachusetts laws protecting tenants, homeowners, utility consumers, and shelter residents, and at least one positive response qualified as a positive screen. After piloting, the screening tool was administered to female patients with public or no health insurance attending a breast health clinic at a safety-net hospital. Performance of the screening tool was validated against a comprehensive, in-person, one-hour legal interview by an attorney followed by a legal evaluation by MLP | Boston, which represented the “gold standard” for detecting housing-related barriers to care. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of the screening tool were computed. Descriptive statistics on demographic characteristics were also calculated.

RESULTS: Of 74 eligible women approached, 35 (47 %) of a targeted sample of 50 consented to participate: mean age 42 years, 54 % African-American, 30 % White, 8 % Latina, and 8 % Other Race. Most subjects had state subsidized health insurance (43 %), Medicaid (26 %), or Medicare (11 %), and 83 % of women had incomes under 200 % of the federal poverty level. While 20 % of subjects owned their home, 57 % rented, 17 % stayed with friends or family, and 6 % had other housing arrangements. Almost 40 % of subjects rated their health as fair or poor. Among the 31 out of 35 women who completed full legal evaluation at the time of analysis, the screening tool had a sensitivity of 89 % (17/19), specificity of 42 % (5/12), PPV of 71 % (17/24), and NPV of 71 % (5/7). Based on the legal evaluation, over 60 % of women had housing-related barriers to care. Among owners and renters, the screening tool was most often positive for threatened disconnection of utility services (10/24 or 42 %), of which 3 were false positives among renters only.

CONCLUSIONS: In this population of low-income, predominantly publicly-insured women, housing-related barriers to care were widespread. When compared to the comprehensive legal assessment by the attorneys, our screening tool had acceptable sensitivity, but modest specificity, for identifying housing-related barriers to care that require legal advice or assistance to resolve. After completion of targeted enrollment, future work will refine which screening questions best identify subjects whose housing-related barriers to care are amenable to legal advocacy and which responses trigger the need for access to legal advice or assistance.

DEVELOPMENT OF QUALITY INDICATORS FOR THE CARE OF WOMEN WITH ABNORMAL UTERINE BLEEDING Donna L. Washington^{1,2}; Marjorie Danz^{1,3}; Kristina M. Cordasco^{1,2}. ¹VA Greater Los Angeles Healthcare, Los Angeles, CA; ²University of California, Los Angeles, Los Angeles, CA; ³RAND Corporation, Santa Monica, CA. (*Tracking ID #1936245*)

BACKGROUND: Abnormal uterine bleeding (AUB) is among the most common gynecologic complaint of reproductive-age women in ambulatory care settings, with

up to 30 % of women seeking medical care for AUB during their reproductive years. International consensus recommendations for standardizing the nomenclature and methods for investigating and categorizing potential AUB etiologies (the FIGO classification system for causes of AUB) were recently developed as an approach to improve our understanding and management of AUB. We sought to translate consensus recommendations and evidence-based guidelines for AUB care into quality indicators (QIs) that are measurable from electronic health records (EHRs), with the ultimate goal of applying these QIs to assess variations in clinical management and aid in women's health education for healthcare providers.

METHODS: To develop QIs, we first performed an extensive literature review to develop a set of potential QIs for the evaluation and management of women with AUB, targeting aspects of care that are within the purview of primary care providers (PCPs). For each potential QI, we specified a numerator, denominator, exclusions, relevant definitions, period of assessment, underlying evidence and data source. We then used a modified Delphi consensus technique based on the RAND/University of California-Los Angeles Appropriateness Method, which consisted of three steps. In step one, nine experts (women's health PCPs, obstetrician/gynecologists, quality measurement experts, policy stakeholders) independently ranked the indicators using nine-point scales on three metrics: consistency with established guidelines; importance to women's health; and reliability of measurement from Veterans Health Administration (VHA) EHRs. In step two, we conducted an expert panel teleconference with internet-based sharing of presentation materials, in which indicators were discussed by the panelists. In the final step, all indicators were independently rated by panelists a second time, using the same nine-point scales. QIs were selected for final inclusion if they had a median score of 7 or higher on all three metrics, and high consistency in their ratings, based on the interpercentile range adjusted for symmetry (IPRAS), using an interpercentile range of 0.3–0.7.

RESULTS: The consensus process resulted in selection of 19 QIs covering multi-dimensional aspects of AUB care, spanning reproductive and post-menopausal life phases, and including profuse vaginal bleeding, and use of hormonal contraception/IUDs. Five QIs relate to documentation of critical aspects of the history; 6 to diagnostic evaluation; and 8 to management. Evaluation QIs highlight the need to recognize pregnancy, need for emergency care, and elevated endometrial cancer risk. Management QIs focus on current profuse bleeding, follow-up of diagnostic studies, and indications for gynecologist referral. Areas of disagreement in panelists' ratings and discussion related to the acceptable timeframe for completion of different actions, with generalist panelists being more likely to consider the constraints of the ambulatory care setting in their decision-making.

CONCLUSIONS: This project resulted in development of a multi-dimensional set of QIs for primary care AUB evaluation and management, based on published data, consensus recommendations and guidelines, and a modified Delphi process. These QIs are being formulated into an EHR quality of care assessment tool. Once this tool is pilot-tested for feasibility, it will be applied on a larger scale to measure the care quality provided to women with AUB in VHA primary care settings. This rigorously designed set of QIs should facilitate measuring and improving the quality of care for women with suspected AUB. Future work should focus on developing educational programs that are concordant with these QIs and assess potential changes in quality outcomes associated with their implementation.

DEVELOPMENT OF THE IORA WORRY SCORE AND COMPARISON TO SUBJECTIVE PROVIDER WORRY SCORES IN MULTIPLE PRIMARY CARE PRACTICES Daniel P. Croft¹; Benjamin Berk²; Whitney Kramer²; Joel Lazar^{2,3}; Rushika Fernandopulle²; Eugene Nelson³. ¹Dartmouth Hitchcock Medical Center, Lebanon, NH; ²Iora Health, Cambridge, MA; ³The Dartmouth Institute for Health Policy & Clinical Practice, Lebanon, NH. (*Tracking ID #1927628*)

BACKGROUND: The degree of provider concern for individual patients significantly impacts panel management decisions and subsequent resource allocation within primary care practices. As current decision support tools do not effectively capture provider concern levels, the Iora Worry Score (IWS) was developed to reflect providers' level of concern for individual Iora Health patients. The primary outcome of interest in this study was the strength of agreement between the IWS and the subjective provider worry score (SPS). This outcome was validated against an established stratification tool, the Milliman Advanced Risk Adjusters (MARA) score. A secondary outcome of interest was the relationship between both worry scores (IWS and SPS) and the average number of primary care visits.

METHODS: Iora Health is a venture-funded health care company based in Cambridge, MA, building a new model of primary care that serves a broad spectrum of patient populations, with a special focus on patients with complex chronic diseases. A patient's IWS was defined as a provider's general level of concern for a patient in terms of the anticipated need for team-based review and potential follow-up. The IWS was reported on a scale of 1 (least concern) to 10 (most concern) and was created using 77 evidence-based utilization, clinical, administrative and patient-reported variables. The IWS was applied to 5,773 patients

across four Iora Health practices in a retrospective review. Iora Health providers assigned a SPS to each patient within a randomly selected subset of 352 patients for inclusion in the analysis of the primary outcome. The Kendall tau rank correlation coefficient was used to determine the strength of agreement in the analysis of IWS, SPS and MARA score.

RESULTS: The randomly selected cohort of 352 patients accurately represented the demographics of the entire Iora Health system population. Though few significant demographic differences were found across the four practices, there was significant variation in the IWS across practices ($p<0.0001$). As the primary outcome, the statistically significant agreement noted between the IWS and the SPS ($p<0.0001$; $\tau=0.47$) was stronger than the agreement between the comparator MARA score and the SPS ($p<0.0001$; $\tau=0.39$). The SPS and the average IWS across all practices both displayed a statistically significant positive relationship with the average number of primary care visits ($p<0.0001$, $\tau=0.43$ and $p<0.0001$, $\tau=0.44$ respectively).

CONCLUSIONS: When compared to an accepted stratification tool, the IWS had a stronger degree of agreement with subjective provider concern levels. Implementing the IWS electronically through Iora Health's care collaboration platform can save provider time by automating the triage of patients for team review and increase the responsiveness of Iora Health to concerning changes in individual patient worry scores. Ongoing refinement of the IWS to improve proactive panel management will be an important effort within the overall movement toward improving primary care delivery and patient outcomes.

DIABETES CONTROL IN OLDER PATIENTS IN PRIMARY CARE CLINIC VS. ENDOCRINOLOGY CLINIC Zoobia Chaudhry; Phil Levin; Lee Bromberger; Hsin-Chieh Yeh. Johns Hopkins School of Medicine, Baltimore, MD. (*Tracking ID #1935937*)

BACKGROUND: With increasing prevalence of diabetes, the demands for appropriate management by primary care providers as well as endocrinologists have amplified significantly. Although primary care providers see the vast majority of patients with type 2 diabetes, very few studies compared diabetes control in patients seen in primary care setting vs. in endocrinology clinic. A study in early 2000s reported a better quality of care in diabetes clinic than in primary care clinic, but no recent data indicated whether the disparity remained. We therefore conducted a retrospective study to compare HbA1c, blood pressure, and lipids controls in diabetic patients age 65 and older who were all eligible for Medicare coverage.

METHODS: A cross-sectional medical record review for older diabetic patients receiving care in 2010 and 2011 was conducted in a primary care clinic (PCC) and in an endocrinology clinic (EC) located in a close geographic proximity in Baltimore City. Data from the PCC included all older patients seen during the study period ($n=713$); data from the EC was a random sample of older patients ($n=100$) from medical chart reviews.

RESULTS: Patients seen in the PCC were older (mean age: 75.5 ± 6.7 vs. 73.3 ± 7.0 , $p=0.002$), were more likely to be black (75 % vs. 14 %, $p<0.0001$), had higher body mass index (BMI, 30.9 ± 6.4 vs. 28.2 ± 7.7 , $p<0.0001$), and were less likely to be on insulin (24 % vs. 38 %, $p=0.004$). There was no difference in gender distribution (women 56 % vs. 54 %, $p=0.69$). In the univariate analysis, patients seen in the PCC and EC had similar mean HbA1c (PCC 6.93 ± 1.5 %, EC 6.99 ± 1.5 %, $p=0.69$), systolic blood pressure (PCC 133 ± 18 mmHg, EC 130 ± 15 mmHg; $p=0.132$), and total cholesterol (PCC 166 ± 40 mg/dl, EC 162 ± 36 mg/dl; $p=0.44$), but had lower diastolic blood pressure (67 ± 12 mmHg vs. 72 ± 10 mmHg; $p=0.0001$) and higher HDL-cholesterol (56 ± 19 mg/dl vs. 51 ± 18 mg/dl; $p=0.006$). In the multivariable linear regressions adjusting for age, race, sex, BMI, and insulin use, compared to patients seen in PCC, patients seen in EC had a significantly lower mean HbA1c (beta-coefficient: -0.57 %; 95 % confidence interval (CI): -0.94 % to -0.19 %, $p=0.003$), but a higher DBP (beta-coefficient: 4.0 mmHg, 95 % CI: 0.88 to 7.14 mmHg; $p=0.012$).

CONCLUSIONS: Glycemic control in older patients with type 2 diabetes was better in patients seen in EC as compared to those seen in PCC, partly due to the use of insulin. On the other hand, patients seen in PCC had a better control on diastolic blood pressure. Future research should explore the differences between the primary care clinic and endocrinology clinic on treatment strategies and other aspects of clinical practices such as counseling on lifestyle changes.

DIABETES EMPOWERMENT PROGRAM: CHANGES IN PATIENT SELF-CONFIDENCE, DIABETES SELF-MANAGEMENT, AND HEALTH OUTCOMES Monica E. Peek; Nora Geary; Yue Gao; Daniel J. Rowell; Yolanda O'Neal; Tonya Roberson; Julie L. Whyte; Nyahne Bergeron; Marshall Chin. University of Chicago, Chicago, IL. (*Tracking ID #1939499*)

BACKGROUND: African-Americans disproportionately suffer from diabetes and its complications. Although culturally tailored education can improve diabetes self-management and health outcomes among this population, little prior work has combined diabetes education with patient/provider communication training to empower African-American patients to better manage their disease.

METHODS: As part of a larger intervention, we developed the Diabetes Empowerment Program, a 10-week program that combined culturally-tailored diabetes education with skills training in patient/provider communication and shared decision-making. The education classes were modeled after the BASICS diabetes curriculum, and were adapted based on principles of health literacy and adult learning theory. Session length was adjusted to reduce the volume of information shared per session and audio visual aids supplemented written materials. The shared-decision making classes focused on building patients' skills and confidence in asking more questions, giving more information, clarifying/restating what the doctor says, and communicating health care preferences. The classes utilized role-play, narrative, group interaction and problem-solving. Following the 10-week session, patients were invited to join a monthly support group for ongoing learning, skills building and social support. Patients were recruited to participate in the classes from two university clinics and four federally qualified health centers. We utilized in-person surveys to measure the following: 1) patients' self-confidence about shared decision-making and diabetes self-management (i.e. decision-making empowerment and diabetes self-efficacy), 2) patient's behaviors regarding diabetes self-management behaviors and shared decision-making (i.e. patients' perceived involvement in care, blood sugar testing, exercise, healthy eating, and foot care), and 3) intermediate health outcomes (i.e. HbA1c, systolic blood pressure, weight and LDL cholesterol). Data were collected at baseline, immediately following the intervention (post), 3-months, and 6-months post intervention. We used linear mixed models to assess changes between baseline data and three follow-up points, controlling for age, gender, education, health insurance, number of years since diabetes

diagnosis, self-reported health status, and co-morbidities (e.g. stroke, asthma, hypertension, hyperlipidemia).

RESULTS: Among the 118 patients (with at least one follow-up data point), the mean age was 57 years, 78 % were female, 97 % were African American and 40 % were uninsured or Medicaid-insured. The average baseline HbA1c was 8.8 %. Patients' self-confidence about diabetes care significantly improved after program participation in decision-making empowerment and diabetes self-efficacy (Table 1). Significant improvements in diabetes self-management behaviors were also observed after program participation. Patients perceived themselves to be more involved in their care, and reported higher frequencies of exercising, testing blood sugar, and doing foot examinations. No significant findings were observed in healthy eating. After program participation, significant changes in intermediate health outcomes were also observed. There was a significant decrease in HbA1c from baseline, which was sustained at the 6-month follow-up. Additionally, a significant decrease in weight was observed at the 6-month follow-up. No significant changes in LDL or systolic blood pressure values were observed.

CONCLUSIONS: Our findings suggest that combining culturally-tailored diabetes education with skills training in patient/provider communication can be an effective strategy to improve self-confidence and behaviors in self-management and shared decision-making, and also improve diabetes-related health outcomes. Such strategies may serve to reduce diabetes disparities among African-Americans.

Changes in self-confidence, diabetes self-management behaviors, and intermediate health outcomes in the Diabetes Empowerment Program

Outcome	Time	Adjusted mean (CI)	p-value
Decision-making empowerment (a)	baseline post 3-month 6-month	80.9 (76.8,85.1) 92.2 (87.7,96.7) 89.2 (83.4,95.0) 90.6 (85.1,96.1)	<0.001 0.002<0.001

DIABETES PREVENTION: ARE WE TRANSLATING EVIDENCE INTO PRACTICE? Tannaz Moin^{1,2}; Jinnan Li²; O. Kenrik Duru²; Susan Ettner²; Norman Turk²; Robert H. Luchs³; Abigail M. Keckhafer³; Anya Kirvan³; Carol Mangione². ¹VA Greater Los Angeles Healthcare System and HSR&D Center for Healthcare Innovation, Los Angeles, CA; ²David Geffen School of Medicine at UCLA, Los Angeles, CA; ³UnitedHealth Group, Minneapolis, MN. (*Tracking ID #1939018*)

BACKGROUND: Pre-diabetes is a major health care burden that is associated with an increased risk of type 2 diabetes and related complications. More than 10 years ago, several landmark studies demonstrated that both lifestyle changes and metformin use can significantly reduce the risk of progression to diabetes compared to placebo. Soon after, the safety, tolerability and cost-effectiveness of metformin use in patients with pre-diabetes was also demonstrated. Beginning in 2008, the use of metformin was included in national diabetes prevention guidelines by the American Diabetes Association (ADA). To date, very little is known about the uptake and translation of the evidence supporting metformin use in patients with pre-diabetes. The goal of this analysis was to characterize national patterns of metformin use among patients with pre-diabetes and examine whether a health plan designed specifically for patients with pre-diabetes and diabetes (the "Diabetes Health Plan," or DHP), which eliminates copayments for metformin and enhances access to care management, could impact the translation of evidence into practice.

METHODS: We conducted a retrospective analysis of claims data from a national commercial health plan between 2009 and 2012. We included patients with pre-diabetes between 19 and 63 years of age with consecutive enrollment over 3 years and compared those who were enrolled in the DHP to those enrolled in a standard medical plan. A diagnosis of pre-diabetes was defined by two or more ICD-9 diagnoses of 790.2x (during an inpatient, outpatient, or ED claim), or last HbA1c

value of 5.7–6.4 %, or last Fasting Plasma Glucose (FPG) value of 100–125 ng/dl or last oral glucose tolerance test (OGTT) value of 140–199 ng/dL. We excluded patients with a history diabetes, gestational diabetes, or use of anti-glycemic medications at baseline.

RESULTS: We analyzed data from 23,843 patients with pre-diabetes and compared results among those enrolled in the DHP (*n*=935) to those enrolled in standard medical plans (*n*=22,908). The prevalence of metformin use among patients with pre-diabetes was similarly low in both groups at baseline (1.9 % in the DHP [*n*=18] and 1.7 % in the standard plans [*n*=382]). Over the following 2 years we observed minimal change in the proportion of patients with pre-diabetes who were newly prescribed metformin whether or not they were enrolled in the DHP (2.1 % new metformin prescriptions in the DHP plan [*n*=19] and 1.2 % in the standard plans [*n*=262]).

CONCLUSIONS: Our findings indicate that metformin is rarely used in the management of pre-diabetes, despite a strong evidence base in the literature for over 10 years. This is a concerning gap in the clinical approach to pre-diabetes and potentially impacts up to one third of the U.S. population currently estimated to have pre-diabetes. Enrollment in a pre-diabetes health plan, which eliminates medication and physician visit copays and increases pre-diabetes disease awareness, minimally increased the rates of metformin use among patients with pre-diabetes. Further studies are needed to understand the root causes of this existing gap and possible interventions to help promote the translation of evidence into future practice.

DIAGNOSING AND COUNSELING OBESE PATIENTS IN THE PRIMARY CARE SETTING Adam J. Balzer; Cynthia Phan; Priya Radhakrishnan. St. Joseph's Hospital and Medical Center, Phoenix, AZ. (*Tracking ID #1938375*)

BACKGROUND: The incidence of obesity in the U.S. has expanded to greater than 30 % of the population and is now widely regarded as a national epidemic. Obesity is defined as a body mass index of greater 30 kg/M2. For years, it has been clearly

linked to several chronic diseases including coronary artery disease, hypertension, and diabetes mellitus. Studies are also demonstrating that obesity is an independent risk factor for prolonged hospitalizations, increased ambulatory care utilization, and increased healthcare costs. While healthcare providers are very aware of detrimental impact of obesity, a systematic approach to obesity as a disease entity and the implementation of a treatment plan does not occur routinely. With the expansion of electronic health record systems and underlying requirement of "meaning use" rules, BMI must be recorded at each clinic visit. If the BMI is outside parameters, a follow-up visit must be documented.

METHODS: With the transformation into a electronic medical record system in the Internal Medicine, we undertook a quality improvement project. Chart review was performed on patients from May 2012 to June 2012 of patients that had appointments at the Internal Medicine Clinic Health Center. Data was collected and analyzed. We looked at the percentage of patients with a documented body mass index of 30 or greater. A chart review was performed for each patient with a BMI of greater than 30 to see if obesity was diagnosed and if counseling was performed.

RESULTS: From 5/1/2012 to 6/18/2012, 744 encounters were analyzed from both residency clinic and faculty practice. Forty-three percent of 744 encounters had a clinical diagnosis of obesity listed in the problem list. Of these, 60 % of those diagnosed received counseling. Of the 744 encounters, there were 557 patients made up the 744 encounters; 142 patients were seen at least two times and 61 % of those patients were diagnosed with obesity.

CONCLUSIONS: The results of this study demonstrate that BMI is consistently measured and recorded in the EMR, however, obesity is not consistently recorded as a diagnosis in the problem list and treatment options are not routinely documented in the EHR. It is interesting to note that despite having multiple encounters, obesity was consistently not clinically diagnosed in 39 % of the patients. This quality improvement project demonstrates the importance of linking education with meaningful use metrics to make a clinical impact. We hope these findings initiate further research on provider understanding of EHR utilization and potential barriers to recognizing and treating obesity in the primary care setting.

DID THE UNITED STATES PREVENTIVE SERVICES TASK FORCE 2005 GUIDELINES FOR ABDOMINAL AORTIC ANEURYSM SCREENING AFFECT MORTALITY IN THE UNITED STATES POPULATION? Devin B. Malik; Sourabh Aggarwal. Western Michigan University School of Medicine, Kalamazoo, MI. (Tracking ID #1938931)

BACKGROUND: An abdominal aortic aneurysm (AAA) is defined when infra-renal aortic diameter is at least 3.0 cm. The United States Preventive Services Task Force (USPSTF) made recommendation in 2005 that all men between the age of 65 to 75 years and who have ever smoked should be screened one time for AAA by abdominal ultrasonography. However, the clinical impact of these recommendations are unknown in the American population.

METHODS: We queried Healthcare Cost and Utilization Project's Nationwide Inpatient Sample (NIS) for AAA and AAA rupture using ICD9 codes 441.4 and 441.3 respectively. The NIS represents 20 % of all hospitals data in US. All the data was extracted for years 2000–2010. The prevalence and in-hospital mortality for pre-screening years (2000–2004) was compared with post-screening years (2006–2010). Chi square was used to find statistical significance.

RESULTS: A total of 527,801 hospitalizations secondary to AAA and AAA rupture were analyzed for the study period. AAA prevalence decreased from 61.72 to 58.77 per 10,000 total hospitalizations with in-hospital mortality decreasing from 3.5 to 2.12 % (*p* value <0.001). On sub-analysis, the decrease in prevalence was chiefly in 65–84 age group (77.19 to 74.54 per 100 AAA admissions, *p*<0.001), with increase in 84+ age group (6.37 to 8.6 per 100 AAA admissions, *p*<0.001) and no significant change in 45–64 age group (16.16 to 16.51 per 100 AAA admissions, *p* value >0.05). Prevalence increased in males (77.84 to 78.13 per 100 AAA admissions, *p*<0.001) and decreased in females (22.13 to 21.81 per 100 AAA admissions, *p*<0.001). Decrease in mortality was uniform in all age and gender sub-groups. The prevalence of AAA rupture decreased from 9.51 to 7.03 per 10,000 total hospitalizations (*p*<0.001). On sub-analysis decrease in prevalence was reciprocated in 65–84 age group (70.08 to 64.94 per 100 AAA rupture admissions, *p* value <0.001) and males (73.23 to 71.7 per 100 AAA rupture admissions, *p* value <0.001). However, prevalence of AAA rupture increased in age group 45–64 (14.41 to 15.43 per 100 AAA rupture admissions, *p* value <0.001), age 84+ (15.21 to 19.2 per 100 AAA rupture admissions, *p* value <0.001) and females (26.28 to 28.28 per 100 AAA rupture admissions, *p* value <0.001).

CONCLUSIONS: Our study reveals that post screening recommendations, hospitalizations for AAA decreased significantly with decrease only reciprocated in the age group 65–84 years. Also hospitalizations and in-hospital mortality from AAA rupture

decreased in males and age group 65–84, with increase in hospitalizations for the 45–64 and 84+ age group and females. The possible explanation is better screening as outpatient resulted in decreased morbidity with decreased hospitalizations from AAA and AAA rupture in susceptible population. Our study also makes the case to consider extension of recommendations to include other susceptible groups.

DIFFERENCES IN ACCESS TO HEALTH CARE AMONG LESBIAN, GAY, AND BISEXUAL POPULATIONS IN NEW YORK CITY Kristin A. Swedish¹; Marcus A. Bachhuber²; Viraj V. Patel¹. ¹Montefiore Medical Center, Bronx, NY; ²University of Pennsylvania, Philadelphia, PA. (Tracking ID #1938935)

BACKGROUND: Lesbian, gay, and bisexual (LGB) groups in the United States experience significant health care disparities across a wide range of conditions. Despite being considered a priority area to target in Healthy People 2020, there is limited nation-wide data available on these populations. Previous research suggests that LGB members of racial or ethnic minorities often face the highest level of health disparities. We examined differences in access to care by self-identified sexual orientation and race/ethnicity in New York City (NYC).

METHODS: We used multi-year pooled data from the 2009–2011 NYC Community Health Surveys, a probability-based survey using a stratified random sampling. The Community Health Survey is based upon the National Behavioral Risk Factor Surveillance System and samples approximately 10,000 adults from all five boroughs of NYC (response rates 37.7–40 % for 2009–2011). We examined two primary outcomes: 1) identifying someone as a primary care provider (PCP) and 2) receiving medical care when needed in the prior 12 months. Self-identified sexual orientation was the primary independent variable, accounting for gender. We conducted descriptive analyses and multivariate logistic regression analyses adjusting for age, race/ethnicity, nativity (US vs. foreign born), education, employment status, insurance status, and primary language spoken at home. All analyses incorporated survey weights.

RESULTS: Survey respondents included 603 gay men, 204 lesbian women, 115 bisexual men, and 133 bisexual women, with mean age 48.9 years (SD 14.9). The majority of LGB individuals were White (59.5 %), college-educated (62.9 %), employed or self-employed (64.9 %), privately insured (57.5 %), and US-born (82 %). Lesbian and bisexual women were significantly less likely than heterosexual women to identify a PCP (adjusted odds ratio [AOR] 0.46, 95 % confidence interval [CI] 0.45–0.47 and AOR 0.66, 95 % CI 0.65–0.68, respectively). Lesbians and bisexual women were also less likely than heterosexual women to have received medical care when needed in the prior 12 months (AOR 0.73, 95 % CI 0.71–0.75 and OR 0.41, 95 % CI 0.40–0.42, respectively). In contrast, when compared to heterosexual men, gay and bisexual men were significantly more likely to have a PCP (AOR 1.09, 95 % CI 1.07–1.11 and AOR 1.22, 95 % 1.18–1.27, respectively). Both gay and bisexual men were also more likely than heterosexual men to have received medical care when needed in the prior 12 months (AOR 1.36, 95 % CI 1.33–1.39 and OR 1.54, 95 % CI 1.47–1.62, respectively). When stratified by race/ethnicity, lesbian and bisexual Black and Hispanic women were significantly less likely than heterosexual white women to have received medical care when needed in the prior 12 months (AOR 0.50, 95 % CI 0.49–0.52 and AOR 0.34, 95 % CI 0.33–0.35, respectively). Gay and bisexual Hispanic men were significantly less likely than heterosexual white men to receive medical care when needed in the prior 12 months (AOR 0.58, 95 % CI 0.56–0.60).

CONCLUSIONS: Lesbian and bisexual women in NYC have worse access to health care when compared with heterosexual women; these disparities are more pronounced in Black and Hispanic women. It is notable that similar disparity is not seen among gay and bisexual men in NYC, apart from the Hispanic subgroup. It is possible that the HIV epidemic may have altered the way gay and bisexual men utilize health care in NYC. It is also possible that lesbian and bisexual women fear greater stigma in the health care setting. Further research is needed to elucidate these disparities. The findings of this study should be used to help public health officials design interventions and policies to increase access to care in LGB populations.

DISCHARGE ROUNDS: IMPLEMENTATION & EFFECTS OF A SYSTEMATIC APPROACH TO EARLY DISCHARGES ON PATIENT THROUGHPUT Krisda Chaiyachati^{1,2}; Andre N. Sofair^{1,2}; Jeremy I. Schwartz^{1,2}; David Chia^{1,2}. ¹Yale School of Medicine, New Haven, CT; ²Waterbury Hospital, Waterbury, CT. (Tracking ID #1922266)

BACKGROUND: Patient throughput is an important aspect of hospital medicine. It has effects on patient satisfaction and safe transitions of care from home-to-hospital by decreasing emergency room wait times, time to evaluation by a physician, and

time to hospital admission. Early discharges benefit these upstream events by creating bed space and allowing support staff to plan accordingly, setting up a cycle of events necessary for new hospital admissions to begin.

METHODS: In order to improve throughput, our internal medicine residency program systematically instituted daily early morning discharge rounds on the inpatient teaching service on August 1, 2013. Discharge rounds require that each medical team identifies potential discharges and completes the necessary paperwork the day prior to anticipated discharge. The following day, these patients are evaluated early and discharge orders are initiated in real-time. We conducted a retrospective pre-post study to determine whether discharge rounds were effective in changing when discharge orders were initiated and when patients actually left the hospital. To account for changes in practice patterns, we compared the mean time outcomes one month pre- and post-intervention. Moreover, we followed the intervention for two additional months to assess for sustainability.

RESULTS: A total 159 patients in July and 152 in August were discharged by the teaching service. The intervention was associated with earlier discharge order initiation by 59 min (1:07 PM vs. 12:08 PM, $p=0.001$). This effect was consistent for patients being discharged to home (12:54 PM vs. 12:03 PM, $p=0.01$) and to facility (1:32 PM vs. 12:22 PM, $p=0.05$). The percentage of early discharges, namely discharges initiated before 11 AM, increased from 21.4 to 38.8 % ($p=<0.001$). The intervention was associated with patients leaving the hospital earlier 50 min (3:21 PM vs. 2:31 PM, $p=0.005$). This was significant in patients being discharged to home (2:46 PM vs. 2:05 PM, $p=0.05$) but not in those discharged to facility (4:22 PM vs. 3:46 PM, $p=0.28$). These beneficial effects, however, waned in the subsequent 2 months compared with pre-intervention times. In September and October, the mean discharge order initiation times were 1:00 PM ($p=0.69$) and 1:11 PM ($p=0.82$), respectively, while the mean discharge times were 3:22 PM ($p=0.94$) and 3:42 PM ($p=0.22$), respectively.

CONCLUSIONS: The systematic implementation of early discharge rounds significantly decreased the time to initiation of discharge orders and subsequently the time of patient discharge in the immediate period after the intervention. Academic internal medicine services may help improve patient throughput by implementing this intervention. However, as in other quality improvement efforts, consistent reinforcement and reevaluation are likely required for sustainability.

DISCORDANT WEIGHT PERCEPTION AND PHYSICAL ACTIVITY IN OVERWEIGHT AND OBESE WOMEN: IS WEIGHT MISPERCEPTION PROTECTIVE? Nathalie Moise¹; Robert Sciacca²; Juviza Rodriguez²; Ian M. Kronish¹; Elsa-Grace V. Giardina². ¹Columbia University Medical Center, New York, NY; ²Columbia University Medical Center, New York, NY. (Tracking ID #1926824)

BACKGROUND: One third of U.S. adult women (35.8 %) are obese, placing them at increased risk for cardiovascular disease and mortality. Women are approximately twice as likely to be inactive as men while overweight and obese individuals are less likely to exercise than their normal weight counterparts. Understanding drivers of behavioral change in this population is crucial. Prior studies have suggested that within overweight and obese men, weight underestimation is associated with physical inactivity. However, these studies have relied on self-report, both of weight perception and body mass index (BMI), and have been inconclusive regarding the relationship between weight perception and physical activity in women, whose responses may be particularly influenced by social desirability bias. To address this gap, we assessed whether weight perception measured with a figural rating scale is associated with physical inactivity in overweight and obese women.

METHODS: A cross sectional analysis was conducted on a primary prevention cohort of 580 overweight and obese ($BMI \geq 25$ kg/m²) women recruited from the primary care clinics of Columbia University Medical Center. Exclusion criteria were known coronary artery disease, cardiovascular disease, stroke, pregnancy and age ≤ 18 years. BMI was calculated from measured heights and weights. The outcome variable was based on American Heart Association recommendations of at least 30 min of physical activity on most days, which was subdivided into (a) walking exercise and (b) non-walking exercise. Participants indicated their "self" figure on the Stunkard 9-figure rating scale (FRS), a widely used and validated measure for assessing weight status. Accurate weight perception was determined by comparing participants' actual BMI with the BMI matched to the selected figure: Underestimators selected underweight or normal weight figures on the FRS and accurate estimators selected overweight or obese figures that matched their BMI. Multivariable logistic regression was used to analyze the relationship between accuracy of weight perception and physical activity after adjusting for age, race, education and BMI.

RESULTS: Mean age was 48+14 years; 45.3 % were obese, 65.3 % were Hispanic, 41.6 % had hypertension, 30.7 % had hyperlipidemia, 13.4 % had diabetes mellitus and 28.1 % had 2 or more cardiovascular risk factors. Among participants, 49.2 %

correctly perceived their weight and 82.0 % reported they were physically active; 64.6 % reported walking exercise and 41.8 % non-walking exercise. Those who underestimated their weight, compared to accurate estimators, were more likely to be non-Hispanic black (12.9 % vs. 6.7 %, $p<0.0001$), Hispanic (70.8 % vs. 60.0 %, $p=0.0001$), have 9–12 years of education as opposed to >12 years of education (40.6 % vs. 30.6 %, $p=0.02$) and be obese (57.8 % vs. 32.3 %, $p=<0.0001$). Those who underestimated their weight reported more physical activity (adjusted odds ratio [AOR]=1.89, 95 % CI, 1.19–2.99, $p=0.0072$) and non-walking exercise (AOR=1.52, 95 % CI, 1.05–2.21, $p=0.026$), but not walking exercise (Table 1).

CONCLUSIONS: Among overweight and obese women, contrary to our hypothesis, those who underestimated their weights were more likely to report increased physical activity. Accurately perceiving oneself as overweight or obese may be a cognitive barrier to physical activity participation. Additionally, we found that obesity, lower educational attainment and minority race were associated with physical inactivity; physicians should continue to focus on these at risk groups. Because we relied on self-report for physical activity, it may be that individuals who underestimate their weight report greater physical activity. Future studies using objective measures of physical activity are needed to better understand the directionality of this association. Notwithstanding this limitation, clinicians should be aware of weight misperception when counseling overweight and obese patients and should be cautious about reinforcing a self-image that is counter to physical activity.

DISCRIMINATION PERCEIVED BY FREQUENT EMERGENCY DEPARTMENT USERS. IS DISCRIMINATION A RISK FACTOR FOR VULNERABILITY? Stéphanie Baggio¹; Jean-Bernard Daepen²; Bernard Burnand²; Olivier Hugli²; Ornella Ruggen²; Jean-Blaise Wasserfallen²; Karine Moschetti²; Philippe Staeger²; Séverine Alary²; Katia Iglesias²; Marina Canepa Allen²; Patrick Bodenmann². ¹Lausanne University, Lausanne, Switzerland; ²Lausanne University Hospital, Lausanne, Switzerland. (Tracking ID #1930275)

BACKGROUND: Frequent Emergency Department (ED) users are often vulnerable people with many risk factors and health needs. They are also perceived to be time-consuming, "illegitimate" patients, and thus may feel discriminated against during their hospital visit. Because perception of discrimination, non-adherence to medical treatment, and poorer health status are associated, frequent ED users' perception of discrimination may constitute an additional risk factor for vulnerability. The aim of this study was to investigate the relationship between perceived discrimination and vulnerability among frequent ED users.

METHODS: Data were part of a baseline assessment of a randomized controlled trial designed to improve frequent users' quality of care in Lausanne University Hospital, one of the two French-speaking Swiss tertiary care hospitals, with over 50,000 annual ED visits. In total, 250 frequent ED users (≥ 5 attendances during the previous 12 months; ≥ 18 years) were interviewed between May 2012 and July 2013. From a previously published questionnaire, 15 dichotomous sources of discrimination, grouped into five causes of discrimination (any cause, immigration-related, age/gender, physical characteristics/sexual orientation, and social/economic status) were

assessed. Vulnerability was assessed using health status: objective health status evaluated by health-care practitioners and including somatic-, mental-health-, behavioural-, and social issues (dichotomous variables), and subjective health status self-rated by the frequent ED users, including health-related quality of life (WHOQOL), quality of life (EUROQOL), and satisfaction with care (mean-scores). Associations between perceived discrimination and health status were tested with exact Fischer tests and Mann-Whitney U tests.

RESULTS: Participants were 46.2±18.9 years old on average, 57.2 % were men, 47.8 % Swiss, 17.7 % European, and 34.5 % non-European. A total of 35.2 % reported at least one source of discrimination. Objective health status was not significantly related to perceived discrimination (e.g. 35.8 % of users discriminated against had somatic issues versus 33.8 % of users not discriminated against, $p>0.05$, see Table 1). Contrariwise, experiencing discrimination was associated with worse subjective health status (e.g. users discriminated against reported a mean-score of 28.16 for WHOQOL health status, versus 39.44 for users not discriminated against, $p<0.001$, see Table 1).

CONCLUSIONS: Perceived discrimination was partially associated with increased vulnerability. Indeed, frequent ED users who experienced discrimination were more likely to self-rate their own health as lower, while health-care practitioners' rating was not related to perceived discrimination. Therefore, experiencing discrimination was not related to "real" health status, but to subjective health status's evaluation. Perceived discrimination seemed to be associated with a negative overall picture of their own health and health care services among frequent ED users, even if their health was not really worse. Health-care practitioners should be aware of this phenomenon, and perceived discrimination may also be of concern in improving interventions and providing optimal care to frequent ED users.

Associations between perceived discrimination and health status

DISPARITIES IN GLYCEMIC AND LIPID CONTROL AMONG DIABETIC PATIENTS IN THE VETERANS ADMINISTRATION: IMPLICATIONS IN THE ERA OF THE AFFORDABLE CARE ACT LeChauncy D. Woodard¹; Salim S. Virani¹; Laura A. Petersen¹; Amber Amspoker¹; Tracy Urech¹; David Ramsey¹; Omolola E. Adepoju¹; Praveen Mehta²; Jeffrey A. Murawsky²; Aanand D. Naik¹.

¹Michael E. DeBakey Medical Center, HSR&D, Houston, TX; ²VISN 12 (Great Lakes), Westchester, IL. (Tracking ID #1931717)

BACKGROUND: Racial and gender disparities in diabetes care are well documented. The Patient Protection and Affordable Care Act offers promise for reducing such disparities by increasing access to care and aligning financial incentives to promote high-quality, comprehensive primary care through delivery models such as the patient-centered medical home (PCMH). Given its widespread transformation to the PCMH model of care, the Veterans Health Administration (VA) serves as an ideal setting in which to examine the impact of universal healthcare access and patient-centered, team-based care on disparities in diabetes outcomes. Thus, we assessed racial and gender disparities in diabetes care among patients receiving care in the VA subsequent to PCMH implementation.

METHODS: We used VA structured clinical data from electronic fields to identify patients with diabetes who received primary care between June 1, 2011 and May 31, 2012, in one Midwestern VA Network encompassing 7 facilities. We assessed differences in glycemic and lipid control between male and female Veterans with diabetes using two VA quality indicators [Hemoglobin (Hb) A1c<9 %, low-density lipoprotein cholesterol (LDL-C)<100 mg/dL]. We then used multilevel logistic regression, accounting for facility-level clustering, to determine whether female gender or race was associated with glycemic and LDL-C control.

RESULTS: Of the 203,897 patients who received care during our study interval, we identified 37,644 patients (18.5 %) with diabetes. The majority of patients were male (97.1 %) and white (73.1 %). Male patients were older than female patients (mean age 62.9 vs. 54.4 years, $p<0.0001$), and were more likely to have co-existing cardiovascular disease (31.6 % vs. 12.8 %, $p<0.0001$) and hypertension (84.5 % vs. 73.5 %, $p<0.0001$), but were less likely than female patients to have co-existing depression (21.2 % vs. 38.3 %, $p<0.0001$). Compared to men, female patients were less likely to achieve glycemic (84.2 % vs. 81.0 %, $p=0.004$) and lipid (72.5 % vs. 57.9 %, $p<0.0001$) control. Adjusting for age, illness burden, comorbidities, receipt of care at a teaching facility, number of primary care visits, and provider type, females were as likely as males to achieve glycemic control (OR 1.07; 95 % CI, 0.87–1.33), but were less likely to have controlled LDL-C levels (OR 0.77; 95 % CI 0.65–0.92). Further, white patients had significantly higher odds than non-white patients of achieving both glycemic (OR 1.21; 95 % CI 1.10–1.33) and lipid (OR 1.29; 95 % CI 1.20–1.40) control.

CONCLUSIONS: Despite universal access to care and widespread PCMH implementation within the VA, both gender and racial disparities in diabetes care persist. Of course, these findings could be due to patient preferences or lower cardiovascular risk among females and thus, clinically appropriate. Our findings suggest that additional efforts to adapt the PCMH model of care to diverse populations by accounting for patient characteristics and patient preferences for care may lead to additional gains in eliminating health disparities among chronically ill patients.

DISPARITIES IN THE TREATMENT OF DEPRESSION AMONG LOW-INCOME RACIALLY AND ETHNICALLY DIVERSE PATIENTS WITH TYPE 2 DIABETES Caroline Presley; Ken Wallston; David Schlundt; Chandra Y. Osborn; Sunil Kripalani; Shari D. Barto; Russell L. Rothman. Vanderbilt University Medical Center, Nashville, TN. (Tracking ID #1928731)

BACKGROUND: Comorbid depression among patients with Type 2 Diabetes (T2DM) is common and has been associated with decreased adherence to self-care and worse glycemic control (A1C). There have been few studies examining disparities in the prevalence of depressive symptoms, antidepressant use, and adequacy of treatment among low-income patients with T2DM. Therefore, we examined the prevalence of depression and adequacy of treatment among a low-income, racially and ethnically diverse sample of patients with T2DM.

METHODS: 406 patients with T2DM were enrolled in a randomized controlled trial evaluating a health literacy intervention for diabetes care at 10 Tennessee Department of Health safety net clinics. At enrollment, data on patient characteristics and clinical information were collected via self-report and from the medical record. Depressive symptoms were assessed with the Center for Epidemiological Studies Depression Scale (CES-D 20, range 0–60), with a score of ≥ 16 indicating possible depression. Patients were considered to be prescribed an antidepressant if their medication list included an SSRI, an SNRI, a TCA, or an atypical antidepressant. Descriptive statistics characterized the sample and identified prevalence rates. Chi-squared analyses and t-tests were used to examine the bivariate relationships between patient characteristics and the presence of depressive symptoms and, separately, depression treatment status. We performed logistic regression analysis of antidepressant use adjusted for age, gender, race, ethnicity, duration of diabetes, education level, level of depressive symptoms (CES-D score), and study intervention status to evaluate the factors impacting antidepressant use in this patient population.

RESULTS: The sample was on average 51 years old (SD 9.6), 61 % were female, 18 % were African American, and 24 % reported Latino ethnicity. Mean education was 11.1 years (SD 3.4). The majority (88 %) reported no health insurance and annual household incomes <\$20,000 (83 %). Mean A1C was 9.2 (SD 2.1). The majority (53 %) had CES-D scores ≥ 16 . There were similar rates of depressive symptoms by race and ethnicity. Despite the high prevalence of depressive symptoms in the overall sample, only 18 % of all patients and 24 % of patients with CES-D scores ≥ 16 were prescribed an antidepressant. Depressive symptoms were higher among patients prescribed an antidepressant compared to those not prescribed an antidepressant (CES-D score 25 (SD 14.5) vs. 17 (SD 11.9), $p<0.0001$). In adjusted analysis, African American/Blacks (AOR 0.25, $p=0.006$) and Latinos (AOR 0.16, $p=0.005$) were significantly less likely to be on an antidepressant compared to non-Hispanic Whites.

CONCLUSIONS: We found a high prevalence of depressive symptoms among a vulnerable population with T2DM. Only a fraction of patients with possible depression were prescribed an antidepressant. Among patients who were prescribed an antidepressant, there were high rates of depressive symptoms suggesting ineffective treatment. African American and Latino patients were significantly less likely to be treated with an antidepressant even with adjustment for presence of depressive symptoms. These data suggest that depression is often unrecognized and inadequately treated in low-income patients with T2DM, especially racial and ethnic minorities, which may have a negative impact on their diabetes control and outcomes.

DO CANCER PATIENTS FARE WELL IN THE ICU? Vijairam Selvaraj; Jane Garb; James Stewart; Jay Steinrub; Thomas Higgins. Baystate medical center, Springfield, MA. (Tracking ID #1895999)

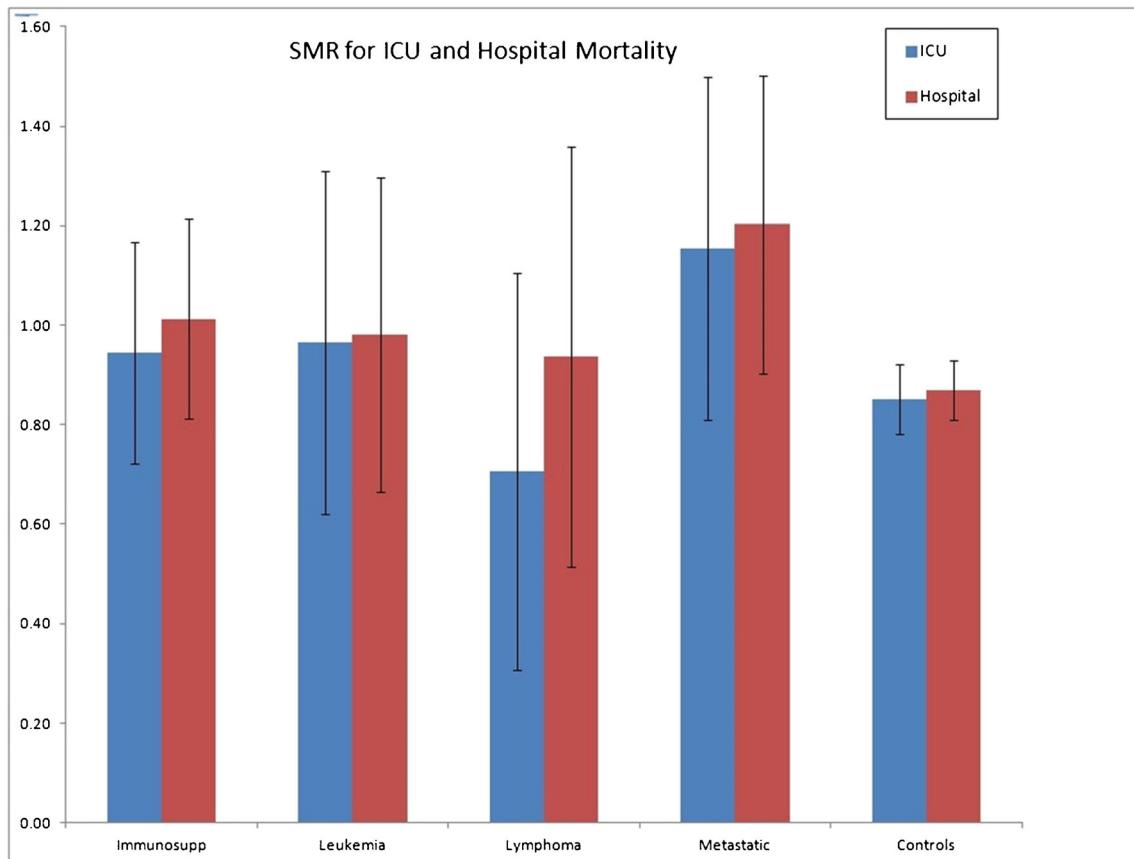

BACKGROUND: Physicians and patients may have unrealistic expectations about prognosis with cancer, with both over- and under-estimates of mortality. While severity of illness at ICU admission is frequently evaluated using the APACHE (Acute Physiology and Chronic Health Evaluation) system, these scores are designed to assess large cohorts rather than individuals and may help with prognostication, but cannot be used to triage ICU admission in isolation. There is long-standing controversy over “potentially ineffective care” and evidence for a high degree of regional variation in caring for patients with poor prognosis cancer. However, newer studies suggest reduced mortality rates among critically ill cancer patients with the development of newer procedures such as non-invasive ventilation. Our hypothesis is that subgroups of patients with cancer may have APACHE-adjusted outcomes similar to non-cancer patients.

METHODS: A retrospective cross-sectional study of all patients above 18 years admitted to the ICU from May 1, 2009 to April 30, 2013 with chronic health diagnoses of leukemia, lymphoma/myeloma, solid tumor with metastasis and immunosuppression at Baystate Medical Center, Springfield, MA. Exclusion criteria was consistent with APACHE-IV methodology. A control group was selected of patients without an APACHE chronic health diagnosis. Primary outcomes were APACHE-IV score and Standardized Mortality Rates (SMR) during ICU and hospital stay. Secondary outcomes included length of stay in ICU and hospital, and mechanical ventilation on day 1 of admission.

Baseline factors in predicting APACHE score were analyzed using multiple regression. Group differences in secondary outcomes were reported descriptively.

RESULTS: 5486 subjects were available for the study: 334 immunosuppressed patients (6 %); 91 leukemia patients (2 %); 50 lymphoma patients (1 %); 162 metastatic cancer patients (3 %); and 4849 non-cancer controls (88 %). All groups were significantly different from controls in Acute Physiology Scores (APS) ($p < 0.001$), after adjusting for age. Mean APS scores for immunosuppressed were 74.3, leukemia 83.6, lymphoma 83.7 and metastatic cancers 68.6; controls were 60.3 ($p < 0.0001$). The age-adjusted regression model accounted for 15 % of the variability in APS scores. While APACHE score significantly discriminated diagnosis groups from controls, there were no significant differences between any groups or controls on APACHE-based SMR's.

CONCLUSIONS: Our study showed patients with cancer or immunosuppression had survival similar to that of non-cancer patients in the ICU; with no difference noted among groups. Because this is a single-site retrospective study, we cannot exclude that triage decisions may be selecting ICU admissions from patients with better prognoses. Further investigation could utilize the national APACHE database to create more generalizable results. Based on this preliminary work, cancer and immunosuppressed patients do not appear to have a mortality penalty in the context of APACHE severity adjustment. This knowledge can help with ICU resource planning as well as timing for palliative care.

SMR for ICU and Hospital Mortality

DO PHYSICIANS SPEND LESS TIME WITH PATIENTS IN CONTACT ISOLATION? A TIME-MOTION STUDY OF INTERNAL MEDICINE INTERNS

Cody Dashiell-Earp¹; Douglas Bell¹; Alexis Ang¹; Daniel Uslan^{2,1}.
¹University of California, Los Angeles, Los Angeles, CA; ²University of California, Los Angeles, Los Angeles, CA. (Tracking ID #1930419)

BACKGROUND: Studies have shown that isolation precautions used by hospitals to control the spread of resistant organisms may have unintended consequences, including a reduction in time spent with health care providers, lower patient satisfaction and more preventable adverse events.

METHODS: The purpose of this study was to measure the time spent by internal medicine interns in contact with patients in isolation compared to non-isolation hospital rooms. Using

RFID tags attached to hospital identification badges, we collected real-time data on the location of 15 internal medicine interns working in our hospital between October 1, 2012 and December 31, 2012. These devices enabled us to record the amount of time spent by interns inside isolated and non-isolated patient rooms. In total, there were 1,156 encounters with isolated patients and 2,467 encounters with non-isolated patients. A mixed model was used to compare the average time spent by each intern with these two patient groups.

RESULTS: Interns visited isolated patients less often (2.3 compared to 2.5 visits per day, $P < 0.0001$) and spent less time per visit with isolated patients (2.2 compared to 2.8 min per visit, $P < 0.0001$). Thus, on average, interns spent 5.2 min per day with each of their isolated patients compared to 6.9 min per day with each of their non-isolated patients ($P < 0.0001$).

CONCLUSIONS: Internal medicine interns spent significantly less time in the rooms of patients in isolation. This difference was more pronounced for some interns compared to others. Reduced physician contact time may be one of the driving forces behind differences in the quality of care experienced by patients in isolation. Further

research is needed, both to better define the patient population for whom the benefits of contact isolation outweigh the risks and to develop strategies to ameliorate those risks for those who must be placed into isolation.

DO PRIMARY CARE PHYSICIANS WHO DELIVER BETTER QUALITY OF CARE ALSO USE LESS HEALTH CARE RESOURCES? Carine Yelib; Charlotte E. Ward; Yuchiao Chang; Jeffrey M. Ashburner; Clemens S. Hong; Steven J. Atlas. Massachusetts General Hospital, Boston, MA. (*Tracking ID #1940237*)

BACKGROUND: Access to and a long-term relationship with a primary care provider (PCP) are associated with better health outcomes and decreased rates of acute care utilization and costs. However, it is less clear whether PCPs that deliver higher quality care also reduce utilization and costs. We hypothesized that PCPs delivering higher quality care have lower rates of emergency department (ED) utilization, admissions, and readmissions.

METHODS: We performed a physician-level, retrospective cohort analysis, using data from calendar year 2012 from electronic data repositories, on 173 PCPs and 105,766 patients receiving care in the MGH primary care practice-based research network. A quality composite measure was created using nine individual HEDIS measures at the patient level, where the denominator was the number of measures for which the patient was eligible, and the numerator was the number of measures the patient achieved (e.g. test completion or goal attainment). The composite measure was dichotomized based on whether the patient received 100 % of services that they were eligible for. The nine HEDIS measures included 3 prevention measures: breast, cervical, and colorectal cancer screening; and 6 chronic disease measures: hemoglobin A1c testing in the prior year and proportion with levels >9.0 % in diabetic patients, low-density lipoprotein cholesterol testing in the previous year and proportion with levels <100 mg/dL for patients with diabetes or coronary artery disease. The outcomes of interest were the number of visits to the ED, inpatient services and the number of 30-day readmissions during the calendar year 2012. These were assessed at the PCP level as a rate of visits/100 patients. Ranking for each physician was created based on the log-odds of achieving 100 % of the HEDIS composite measure using logistic regression models controlling for patient age, gender, ethnicity, language, insurance status, Charlson score, and visit frequency. The relationship between physician quality ranking and utilization outcomes was assessed using linear regression. Rankings were also grouped into quartiles and differences between top and bottom quartiles were assessed using a t-test or Wilcoxon Mann-Whitney test.

RESULTS: Of the 173 PCPs eligible for analysis, 55 % were female, and their mean age was 48. We excluded physicians who were in practice for less than 1 year and those who left during the year of analysis. The percent of eligible patients in a PCP's panel who achieved 100 % of eligible HEDIS measures was 68 % (IQR: 63.6–74.2 %). High physician ranking was predictive of lower ED utilization ($p<0.0001$), admissions ($p=0.0001$) and 30-day readmissions ($p=0.009$). When comparing physicians in the top and bottom quartiles of quality ranking, physicians in the top quartile had significantly lower ED utilization rates (13.1 vs 21.1, $p<0.0001$). Physicians in the top quartile also had significantly lower admission rates than physicians in the bottom quartile (7.3 vs 9.8, $p=0.007$). There was no significant difference in 30-day readmission rates between top and bottom quartile physicians.

CONCLUSIONS: Among primary care physicians within a large, academic network, we found that physicians with higher performance based on a composite of nine quality of care measures was associated with lower ED utilization, admission rates, and 30-day readmission rates. In addition to access to primary care and having a usual source of care, our study suggests that the patients cared for by PCPs with better performance on quality metrics may have lower rates of ED and hospital utilization. Whether patients of such PCPs also have lower health care costs requires further study.

DO RESIDENT-RN ROUNDS REDUCE CALLS TO THE ONCALL PERSON?

(D. R. R. O. P): A QUALITY IMPROVEMENT PROJECT IN THE ICU Maria Yballe^{1,2}; Sehrish Memon^{1,2}; Sandra Kurup^{1,2}; Gen Bahrt¹; Jeana Reyes¹; Michael P. Carson^{1,2}. ¹Jersey Shore University Medical Center, Neptune, NJ; ²Rutgers - Robert Wood Johnson Medical School, Piscataway, NJ. (*Tracking ID #1913456*)

BACKGROUND: On-call ICU/CCU residents receive many calls from nurses during their overnight shift regarding orders that, in theory, could have been placed by day team residents. These interrupt nursing and physician care, and could distract caregivers from more urgent matters, or contribute to sleep deprivation. The first objective was to determine the number of, and reasons for, calls from nursing to the on-call night resident. The second objective was to identify the most common reasons, modify the process so that the day team would address these orders prior to leaving, and then resample to determine if this educational intervention reduced the number of calls made to on-call residents.

METHODS: Baseline Call Rate: The ICU night resident logged and categorized calls for 20 nights to determine the baseline. Based on the common reasons for calls, we

developed a laminated card listing the common issues, distributed it to the nursing and resident staff to use as a reference during end of Day-shift sign-out rounds, and oriented them to the process. Re-Evaluation Call Rate: calls were reassessed 2 weeks later for 10 nights. We coordinated with the ICU nurse manager, nurse educator, and staff nurses. T-test was used to compare the Baseline and Re-Evaluation call rates.

RESULTS: Baseline: 592 calls over 20 nights, Mean 29.6+/-8 calls/night, Range 14–46. The top seven reasons were associated with 81 % of the calls: electrolytes 35 %, medication change 15 %, ventilator change 11 %, order for routine morning labs 11 %, insulin 5 %, diet/NPO 3 %, NG-tube 3 %. Re-evaluation: There were 133 calls over 10 nights; Mean 13+/-4 calls/night (range 5–19) for an average decrease of 16 calls/night. A matched analysis of the 10 lowest nights during the Baseline period vs. the 10 during the Re-evaluation yielded a significant average decline of 10 calls/night [95 % C.I. (4,16)]. Comparing the 10 highest Baseline nights to the 10 Re-evaluation yielded an average decrease of 26 calls/night [95 % C.I. (14,37)]. Calls/night decreased as follows: Electrolytes drop of 3, medication decreased from 4 to 1, routine labs/imaging from 3 to 1.

CONCLUSIONS: A simple program educating the residents to address common orders at the end of the day shift, and nurses to remind the residents to do so, was effective and decreased calls to the night residents by 55 %. This decrease in calls regarding issues that should be addressed by the primary day team was noticed and appreciated by the night resident and nursing staff. The day shift process has been modified, and a repeat survey will be done to assess resident/nursing adherence to this modification. With continued use we anticipate a culture change will result in an additional and sustained decrease in calls for these issues.

DOES RESEARCH TRAINING DURING RESIDENCY PROMOTE SCHOLARSHIP? A CROSS-SECTIONAL ANALYSIS OF A TEN-YEAR COHORT OF THE UCSF-PRIME RESIDENCY PROGRAM Marion Stanley; Jeff Kohlwes; Bridget O'Brien; Rebecca L. Shunk; Denise M. Connor; Patricia A. Cornett; Harry Hollander. VAMC/UCSF, San Francisco, CA. (*Tracking ID #1941144*)

BACKGROUND: Professional organizations, including the Association of Program Directors in Internal Medicine (APDIM), the Accreditation Council for Graduate Medical Education (ACGME), the Alliance for Academic Internal Medicine Education Redesign Task Force as well as the Carnegie study on medical education call for individualized training approaches to ensure that residents have sufficient experience with the various roles of physicians to make informed career choices. In 2000, the Primary Medical Education (PRIME) track of the University of California, San Francisco (UCSF) categorical residency program implemented a novel clinical outcomes research immersion curriculum to enable residents to experience a research career during residency. In PRIME, residents receive a research training course, mentoring and protected time to complete a project in their area of interest. We examined whether implementation of the PRIME clinical outcomes research track led to increased resident publications, improved mentoring and/or subsequent alumni careers in outcomes research as compared to peers at UCSF.

METHODS: We performed a cross sectional analysis of an email survey of internal medicine residency alumni from the UCSF categorical residency program who graduated from 2001 to 2010. We used Pearson Chi-Square analysis and ANOVA to compare PRIME and non-PRIME alumni on categorical and continuous variables.

RESULTS: From 2001 to 2010, 316 categorical residents became alumni. 211/316 (66 %) responded to the survey. A significantly higher percentage of PRIME alumni published research projects they worked on during residency compared to non-PRIME alumni (64 % vs. 40 %; $p=0.002$). A non-significant trend showed PRIME alumni identifying clinical or translational research as their primary career role (35 % of PRIME vs. 29 % non-PRIME) and spending a higher percentage of their professional time conducting research compared to non-PRIME alumni (26 % for PRIME, 21 % for non-PRIME). Process measures that could explain these findings include adequate access to mentors (mean 4.4 for PRIME vs. 3.6 for non-PRIME alumni ($p<.001$)) on a 5 point Likert scale (strongly disagree to strongly agree) and agreeing that mentoring relationships affected career choice (mean 4.2 for PRIME vs. 3.7 for categorical alumni ($p=0.001$)). Finally, 63 % of PRIME alumni agreed that their research experience during residency influenced their subsequent career choice versus 46 % amongst the non-PRIME alumni.

CONCLUSIONS: Our results support that giving residents an opportunity to try out a career in outcomes research during residency enables them to publish their residency-related research more frequently than those who did not have this opportunity. This experience significantly influenced subsequent career choice and may make housestaff more likely to continue doing outcomes research after residency. Implications: Implementation of individualized residency programs tracks that nurture academic interests along with clinical skills will foster important alternative careers within medicine for the graduates who experience them.

EARLY OUTPATIENT FOLLOW-UP AFTER STROKE REDUCES NEIGHBORHOOD SOCIOECONOMIC DISPARITIES IN MORTALITY Arleen F. Brown¹; Li-Jung Liang¹; Stefanie D. Vassar¹; Sharon S. Merkin²; Jose J. Escarce¹; Bruce Ovbiagele³; W. T. Longstreth⁴. ¹UCLA, Los Angeles, CA; ²UCLA, Los Angeles, CA; ³Medical University of South Carolina, Charleston, SC; ⁴University of Washington, Seattle, WA. (*Tracking ID #1939240*)

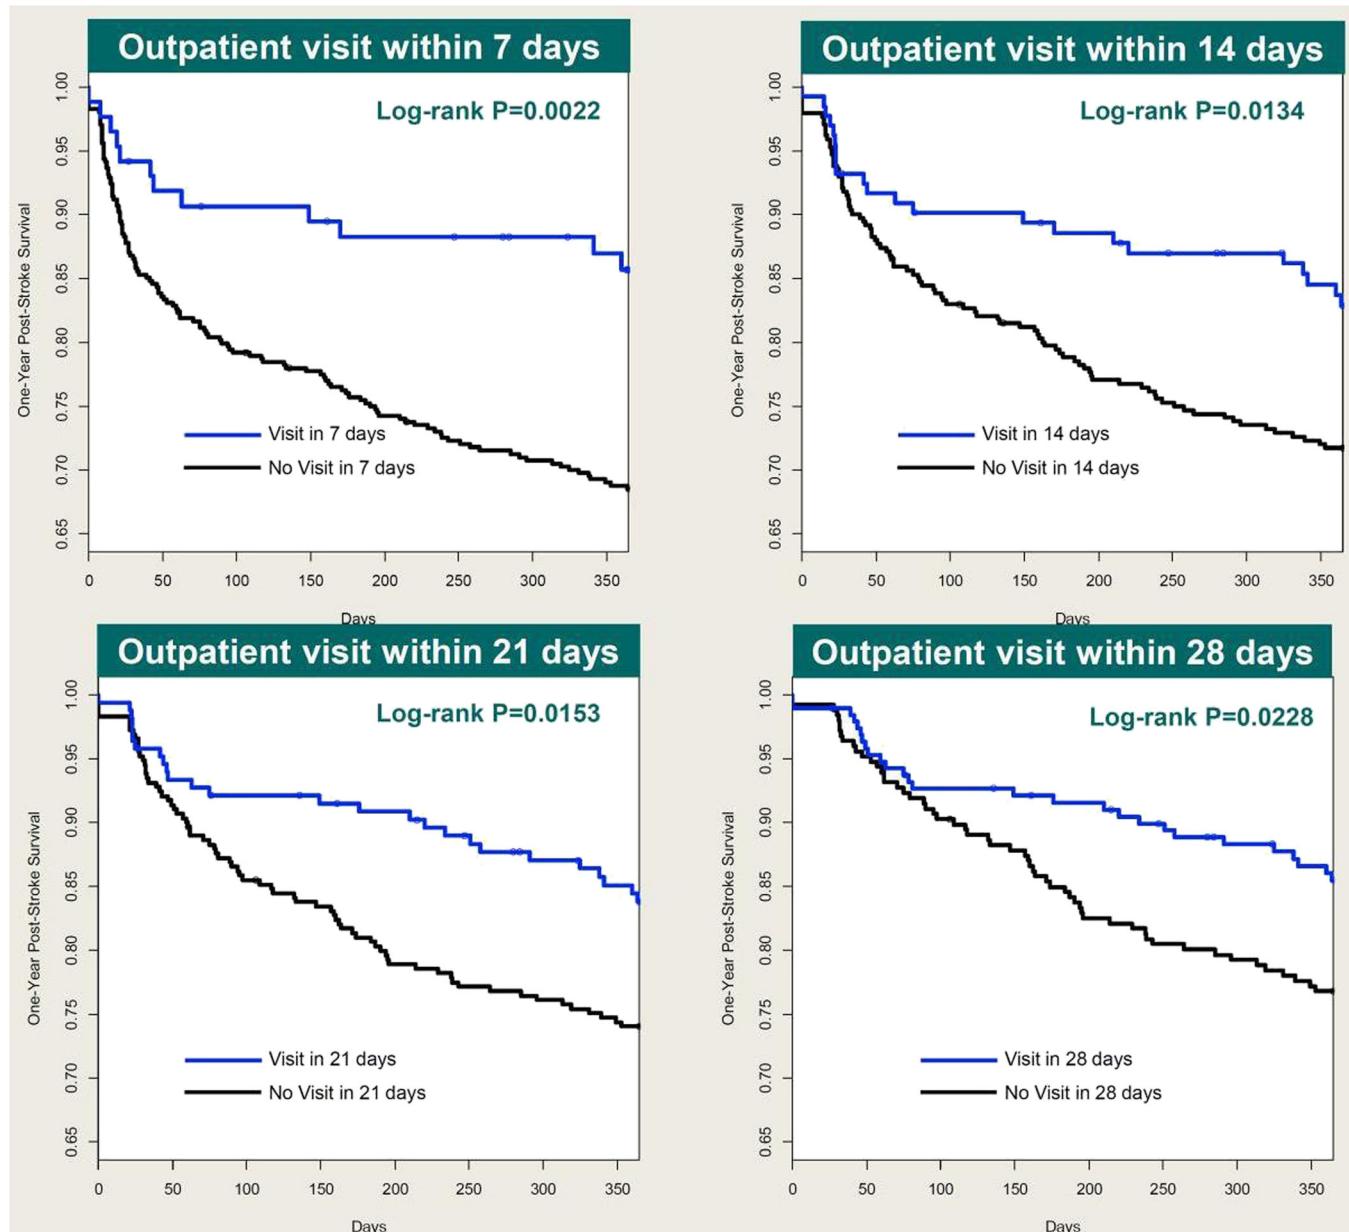

BACKGROUND: Older adults who reside in disadvantaged communities have higher mortality after stroke. We examined whether the timing of post-stroke outpatient visits contributed to previously observed neighborhood disparities in post-stroke mortality.

METHODS: We used data from the Cardiovascular Health Study, a population-based, longitudinal study of adults ≥ 65 years. Center for Medicare and Medicaid Services (CMS) data were used to obtain the number and dates of outpatient visits and pre-stroke comorbidity. Eligible participants had an incident stroke during the study period, survived through the visit interval (7, 14, 21, or 28 days), were matched to CMS records, and had fee-for-service coverage during the follow up period. Neighborhood socioeconomic status (NSES) was a composite of six census variables (median household income; median value of housing units; % of households with interest, dividend, or rental income; % of residents >25 years with a high school education; % of residents >25 years with a college degree; and % of residents in executive, managerial, or professional specialty occupations). To

examine the associations between time to first post-stroke outpatient visit, NSES, and the dependent variable of mortality at 1 year post-stroke, we constructed multilevel Cox proportional hazard models that also included age, sex, race, stroke type, comorbidity score, and an interaction term between time to first visit and NSES. Separate models were constructed for each visit interval.

RESULTS: Among the 495 eligible participants (mean follow up 11.5 years), 17.4 % had an outpatient visit within 7 days, 27.9 % within 14 days, 36.3 % within 21 days, and 43.6 % within 28 days. In adjusted models, the mortality hazard at 1 year after stroke was lower among participants without, compared to those with, an outpatient visit within 7 days ($HR=0.42$; 95 % CI=0.23, 0.79), 14 days ($HR=0.53$; 95 % CI=0.32, 0.85), 21 days ($HR=0.52$; 95 % CI=0.32, 0.83), and 28 days ($HR=0.59$; 95 % CI=0.36, 0.95). NSES was associated with mortality only for models of outpatient visits within 28 days. The visit x NSES interaction was not significant for any models.

CONCLUSIONS: Early follow up after stroke, specifically a visit within the first 3 weeks, was associated with lower mortality at 1 year and appeared to mitigate the association between lower NSES and stroke mortality. For those with later follow up, lower NSES remained independently associated with mortality. Early and appropriate clinical care may play an important role in reducing neighborhood socioeconomic disparities in stroke mortality. These findings suggest a role for community-level interventions to support secondary prevention after stroke.

EARLY PALLIATIVE CARE CONSULTATION IS ASSOCIATED WITH IMPROVED SUPPORTIVE CARE CANCER QUALITY FOR VETERANS

Anne M. Walling^{2,1}; Diana Tisnado²; Susan Ettner¹; Steven Asch⁴; Sydney M. Dy⁵; Philip Pantoja²; Martin Lee²; Sangeeta Ahluwalia³; Hannah C. Schreibis-Baum²; Karl Lorenz². ¹UCLA, Los Angeles, CA; ²VA Greater Los Angeles Healthcare System, Los Angeles, CA; ³Oregon State University, Corvallis, OR; ⁴VA Palo Alto, Palo Alto, CA; ⁵Johns Hopkins University, Baltimore, MD. (*Tracking ID #1936329*)

BACKGROUND: A growing evidence base suggests that palliative care improves outcomes for patients with life-limiting illness including quality of life and bereaved family members satisfaction with end of life care. Less is known about the processes of care influenced by palliative care that lead to these outcomes in real-world settings. We hypothesized that palliative care consultation is associated with improvement in specific processes of supportive care as measured by the Assessing Symptoms Side Effects and Indicators of Supportive Treatment (ASSIST) quality measures.

METHODS: We studied patterns of non-hospice palliative care consultation and the quality of supportive care using ASSIST process of care measures in a retrospective cohort of 719 patients diagnosed with advanced cancer in 2008 over the period of 3 years or until death who received care in the Veterans Affairs Health System (VA) using rigorous chart abstraction methods (inter-rater agreement >90%). We also studied the association of palliative care consultation and quality of supportive care overall and by domain (information and care planning, pain, non-pain symptoms) using a multivariate regression model. Our main predictor variable was the proportion of time (from diagnosis of metastatic disease to death or end of study) a patient with advanced cancer was exposed to palliative care (range 0–1). Our main outcome variable was a patient-level overall quality score calculated with the scores of 40 process quality measures. To take into account that different patients are eligible for different quality indicators with varying pass-rates, we used an observed minus expected score. Using this methodology, a patient's observed score is weighed against an average hypothetical patient who was eligible for the same quality indicator pattern. We conducted standard OLS regression controlling for variables pre-specified as important in our conceptual model of quality palliative care. To address the potential for treatment selection, we also conducted a sensitivity analysis using doubly robust propensity score methods and found similar results.

RESULTS: Of 719 patients, all but 54 patients died before the end of the study period and 293 received a palliative care consult at least once during the study period. On average, patients who had involvement of palliative care received their first palliative care consult towards the second half of their disease trajectory between diagnosis and death or end of study. Controlling for other variables, patients who receive a palliative care consult at time of diagnosis receive 7% higher quality overall ($P<0.001$) and 11% higher quality ($p<0.001$) within the information and care planning domain compared to patients who do not receive a consult, with non-significant improvements within the pain and non-pain domains.

CONCLUSIONS: Earlier palliative care leads to a higher process of care quality score in lung, colorectal, and pancreatic cancer, predominantly driven by improvements in the domain of information and care planning. This study supports the effectiveness of early palliative care in three common advanced cancers within the VA.

EARLY WINNERS AND LOSERS IN DIALYSIS CENTER PAY-FOR-PERFORMANCE

Milda R. Saunders¹; Marshall Chin². ¹University of Chicago, Chicago, IL; ²University of Chicago, Chicago, IL. (*Tracking ID #1938490*)

BACKGROUND: In 2012, the Centers for Medicare and Medicaid Services (CMS) began the End Stage Renal Disease Quality Incentive Plan (ESRD QIP), a pay-for-performance program for dialysis facilities. Examination of QIP may be instructive as a case-study of the ability of financial incentives both to improve quality and impact disparities. Here we examine the impact of ESRD QIP for dialysis facilities overall, by facility characteristics, neighborhood demographics and region. We also examine how ESRD QIP had its impact by examining changes in its three clinical performance measures over time.

METHODS: Our data sources were the 2012 CMS ESRD QIP Facility Performance File, which contained total performance scores (TPS)—range 1–30—for most CMS certified facilities ($n=5005$) in the US, linked to US Census data by zip code. Each facility's TPS is based on weighted clinical performance measures for dialysis adequacy (urea reduction rate >65) and hemoglobin outside of the targeted range (% of patients with hemoglobin (Hgb) <10 g/dL and % patients with Hgb >12 g/dL). Per QIP, facilities with a TPS less than 26 (of 30) will have their payments reduced on a sliding scale, ranging from 0.5 to 2 %. We dichotomized the outcomes as 'any payment reduction' versus 'no payment reduction', and 'large payment reduction' (>1.5 %) versus 'other' (<1.5 %). We used logistic regression to characterize associations between QIP performance and dialysis facility characteristics, neighborhood demographics, and region. To determine how the QIP impacts facility outcomes, we used linear regression to examine changes in dialysis facility outcomes between 2007 and 2010.

RESULTS: Only 30 % of facilities will have any payment reduction in 2012. In multivariable analysis, dialysis facilities with any payment reductions were more likely to have more dialysis stations (OR 1.02 per station, 95 % CI 1.01, 1.03), longer operation (OR 1.03 per year, 95 % CI 1.02, 1.04) and a greater proportion of African-Americans in the neighborhood (lowest versus highest quartile, OR 1.34, 95 % CI 1.08, 1.65). Only a small proportion of facilities (8 %) had a large payment reduction, >1.5 %. Facilities with large payment reductions were less likely to be for-profit (OR 0.69, 95 % CI 0.53, 0.89) and less likely to be in the South and West (OR 0.65, 95 % CI 0.50, 0.85 and OR 0.40, 95 % CI 0.27, 0.59, respectively compared to facilities in the Midwest). Decline in the percentage of patients with a hemoglobin >12 g/dL was largely responsible for improvement in clinical outcomes between 2007 and 2010. For-profit status and increasing proportion of African-Americans in the neighborhood were associated with greater reduction in percentage of patients with hemoglobin above the targeted range (>12 g/dL).

CONCLUSIONS: In the first year of CMS pay-for-performance, a large proportion of dialysis facilities met or exceeded national standards and received no payment reduction. Facilities in African-American communities were more likely to receive a payment reduction despite large improvements in hemoglobin within the targeted range. As the number of outcomes increase and total performance thresholds rise, the quality chasm may widen.

ECONSULTS: CONTENT ANALYSIS OF PCP QUESTIONS, SPECIALIST ADVICE, AND PCP RESPONSES

Katherine Wrenn; Nathaniel Gleason; Sereina Catschegn; Marisa Cruz; Ralph Gonzales. University of California, San Francisco, San Francisco, CA. (*Tracking ID #1938360*)

BACKGROUND: Electronic consults (eConsults) have been proposed as one strategy to help address the excess demand for specialty care, but little is known about the specific types of clinical questions primary care providers (PCPs) are asking through an eConsult program, and how they respond to specialist recommendations. An eConsult service was implemented at the University of California, San Francisco (UCSF) in 2012, in which PCPs can initiate an asynchronous exchange of information with a specialist, posing a clinical question and receiving a response within 3 days, without the need for in-person consultation. The objectives of this study were to describe the types of clinical questions PCPs are asking in eConsults, describe the types of advice specialists are providing, and explore to what extent PCPs implement specialist recommendations.

METHODS: We conducted this study at UCSF, a multi-site academic medical center that includes eight adult primary care practice sites and uses a shared electronic health record (EHR). The following medicine subspecialties participated in the first phase of the eConsult program: Cardiology, Endocrinology, Gastroenterology/Hepatology, Pulmonary Medicine, Rheumatology, and Nephrology. We analyzed the narratives of 98 of the first 158 eConsults completed during the first 2 months of the program. We categorized each eConsult into the following types of questions and responses: "Diagnosis," "Treatment," and/or "Monitoring." The principal investigator (KW) reviewed all 98 eConsults. A second independent reviewer (MC) coded 15 eConsults and specialist responses using coding instructions created by the first reviewer, to check for inter-rater reliability. Kappa statistics ranged between 0.60 (PCP "Diagnosis") and 1.0 (PCP "Monitoring" and Specialist "Monitoring" categories). Chart abstraction was performed to determine what proportion of specialists' recommendations PCPs implemented over the 6 months following completion of the eConsult. We report the results of abstractions from the first 50 eConsults.

RESULTS: In our study sample, PCPs asked questions related to diagnosis in 68.4 % of cases, treatment in 49.0 % of cases, and monitoring in 22.4 % of cases. Among specialist responses, 74.5 % related to diagnosis, 66.3 % to treatment, and 36.7 % to monitoring. The types of questions asked by PCPs varied based on the specialty they were consulting. Diagnosis-related questions were dominant (≥ 80 %) for Cardiology, Nephrology, Pulmonary Medicine, and Rheumatology, whereas treatment-related questions were dominant (>70 %) for Endocrinology. The majority of eConsults included only one type of question posed by the PCP, whereas specialist responses often provided additional recommendations pertaining to more than one category of response (Figure 1). Based on chart review, we found that PCPs ordered 76.5 % of all recommended laboratory tests, 92.3 % of recommended imaging tests or procedures, 66.7 % of recommended new medications, and 85.7 % of recommended medication changes. 24.0 % of eConsult patients had a visit with the specialist during the 6-month period following the eConsult, 4.0 % had an unrelated emergency department (ED) visit, and 8.0 % had a hospitalization, of which 75.0 % were unrelated to the condition in the eConsult.

CONCLUSIONS: We find that eConsults include clinical questions across the spectrum of patient care: diagnosis, treatment, and monitoring of multiple different medical conditions. We also find that PCPs implement specialists' recommendations in the large majority of cases, and very few patients subsequently require specialty care or ED visits related to the reason for eConsult.

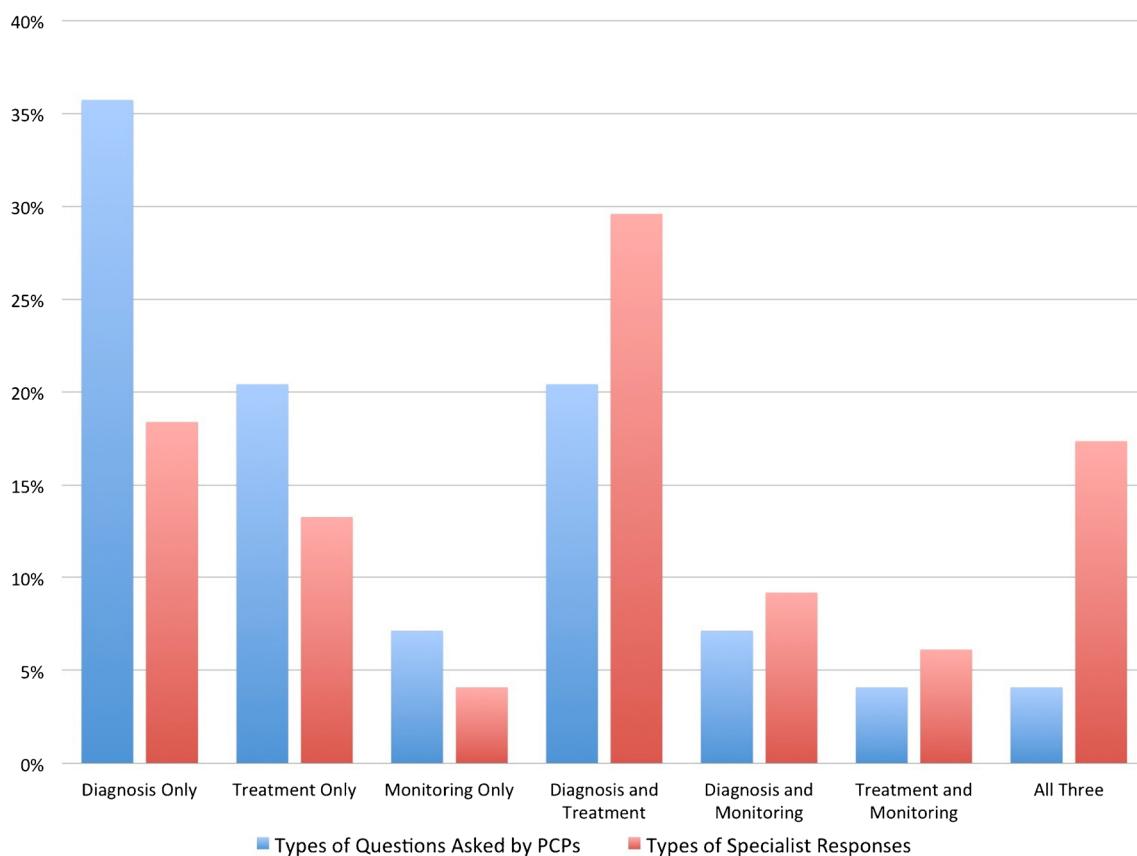

Figure 1. Content of eConsult Questions and Responses.

ED VISITS AFTER MEDICAL HOME IMPLEMENTATION IN VA PRIMARY CARE CLINICS Kristina M. Cordasco²; Jean Yoon¹; Adam Chow¹; Lisa V. Rubenstein². ¹Palo Alto VA, Menlo Park, CA; ²Greater Los Angeles VA, Los Angeles, CA. (*Tracking ID #1940650*)

BACKGROUND: Implementation of the VA medical home model aimed, in part, to reduce unnecessary acute care by emphasizing access and continuity within primary care-based teams. We assessed for change in number of ED visits, by different varying types of ED visits, after medical home implementation began in the VA system, and we examined the relationships between primary care clinic-level measures of access and continuity and number of ED visits per patient.

METHODS: We obtained a cohort of 75,532 patients using VA care from fiscal years 2010–2012 in 23 clinics based in three VA medical centers. Patient information on demographics, chronic conditions, and VA ED visits were obtained from outpatient and inpatient files and linked to clinic administrative data over the 3-year period. ED visits were categorized, by discharge diagnosis, into non-emergent, primary care treatable, ED care needed but preventable, ED care needed and not preventable, and mental health-related visits, based on the NYU algorithm. We also obtained annual primary care clinic measures of access (percent of patients receiving primary care within 1 day of requested date, waiting time to third next available appointment) and continuity (percent of visits with primary care provider). We compared mean number of ED visits per patient by year and by clinic access and continuity. We conducted multivariable regressions of number of ED visits per patient adjusting for patient and clinic factors with patient random effects using Poisson regression models for each ED visit type.

RESULTS: Although mean clinic measures of access and continuity improved over the 3-year period, ED visits of any categorization increased from 0.55 per patient in 2010 to 0.58 per patient in 2012 among the study cohort (all $P<0.001$). In multivariable regressions, clinic measures of higher access predicted significantly fewer ED visits that were both emergent and non-emergent (all $P<0.001$) as well as ED visits for psychiatric diagnoses, but was not related to number of ED visits for alcohol and drug use diagnoses. Better clinic continuity predicted fewer ED visits that were non-emergent ($P=0.001$) or ED care needed but preventable ($P<0.001$), but was not significantly related to mean number of ED visits for any mental health diagnoses.

CONCLUSIONS: Implementation of VA's medical home was not associated with an overall lower ED visit rate in a primary care cohort although access and continuity measures were reported to be slightly higher by primary care clinics from 2010 to 2012. In adjusted analyses access measures consistently predicted fewer ED visits across types of visits although access did not impact ED visits for substance use diagnoses or for any mental health diagnoses. Clinic continuity was related to fewer ED visits for certain types of ED care but was not related to ED visits for any mental health diagnoses.

EFFECT OF ELECTRONIC HEALTH RECORD IMPLEMENTATION ON INPATIENT WORK PROCESSES OF INTERNAL MEDICINE RESIDENTS Marianne Zachariah^{1,2}; Erin L. Duffy^{1,2}; Michael A. Pfeffer¹; Douglas Bell^{1,2}. ¹UCLA, Los Angeles, CA; ²UCLA, Los Angeles, CA. (*Tracking ID #1939481*)

BACKGROUND: Electronic health records (EHRs) are rapidly gaining adoption in the U.S. If EHRs increase the time that providers need to spend on documentation and ordering, this might reduce the time available for patient interactions and learning activities. We sought to compare how residents spend their time on inpatient rotations before and after the implementation of a commercial EHR.

METHODS: We shadowed a total of 30 internal medicine residents to observe their usage of time on inpatient general medicine, medical intensive care unit, and coronary care unit rotations, before and after UCLA's March, 2013 launch of the Epic EHR system. Prior to Epic, most clinical documentation was performed using a home-grown computer system and orders were written on paper. After the launch, nearly all documentation and orders were required to be entered in Epic. Fourteen subjects were shadowed prior to the Epic launch and 27 were shadowed in the period from 30 to 120 days after the launch (11 were shadowed both periods). Residents were shadowed only on days when they were not covering another team member or taking morning holdover admissions. Shadowing was performed by trained undergraduate students who recorded the tasks that each resident was conducting each minute between the hours of 7 am and 5 pm. For analysis, certain tasks were grouped together: Write Orders (on paper before Epic, in Epic or on paper afterward); Clinical Documentation (writing admit, discharge and progress notes plus viewing labs, vitals and other patient data); Patient Interaction (time in patient rooms plus hallway conversations with patient or family). Wilcoxon Rank-Sum tests were used to compare time spent on specified task categories.

RESULTS: After Epic implementation, residents spent more time on order writing but not on clinical documentation. The median time spent with patients was 23 % lower after Epic implementation but the difference was not statistically significant. Among residents on general medicine, 6 of 11 (55 %) attended noon conference before Epic vs. 5 of 19 (26 %) afterward, and those who attended spent less time post-Epic (average 51 vs. 26 min.). The median times spent receiving and giving didactic teaching were also lower post-Epic, although the difference was statistically significant only for giving didactic teaching. Time spent in social conversation was higher in the post-Epic period. Median times spent in conversation with nurses and other physicians were also higher post-Epic but the differences weren't statistically significant. The median time spent in conversation with students was lower post-Epic. Among residents who spent any time talking with a student (12 vs. 13), the average time spent was also lower post-Epic (29.9 vs. 19.5 min.).

CONCLUSIONS: After EHR implementation, residents spent more time writing orders and less on teaching activities, with additional trends toward less time with patients and more time in conversations. However, the residents were observed after only 1–4 months of experience with the system, so these results might not represent their longer-term performance.

Median (IQR) Minutes Spent Before/ After EHR Implementation

Task Category	Pre N=14	Post N=27	P-value
Write Orders	18.87 (8.92)	30.70 (10.25)	0.001
Clinical Documentation	109.33 (55.04)	109.02 (46.53)	0.946
Patient Interaction	74.70 (33.08)	57.17 (33.59)	0.128
Didactic Receiving	17.58 (27.08)	8.50 (21.00)	0.504
Didactic Giving	6.04 (13.50)	1.50 (4.00)	0.023
Student Conversation	25.62 (22.63)	0.00 (12.08)	0.004
Physician Conversation	69.72 (84.29)	82.22 (46.92)	0.614
Nurse/Staff Conversation	4.73 (3.33)	10.54 (24.36)	0.407
Social	11.79 (22.88)	27.83 (30.02)	0.032

EFFECT OF FINANCIAL INCENTIVE FOR COLORECTAL CANCER SCREENING ADHERENCE ON APPROPRIATENESS OF COLONOSCOPY ORDERS Thomas B. Morland¹; Marie Synnestvedt²; Steven Honeywell²; Feifei Yang²; Katrina Armstrong³; Carmen E. Guerra². ¹Geisinger Medical Center, Danville, PA; ²Hospital of the University of Pennsylvania, Philadelphia, PA; ³Massachusetts General Hospital, Boston, MA. (Tracking ID #1935049)

BACKGROUND: There is some evidence that financial incentives may help physicians achieve higher rates of preventive health screenings among their patients. However, it is unclear whether these incentives affect the appropriateness of screening tests physicians order. In July of 2010 the University of Pennsylvania Health System implemented a performance incentive for general internists based upon achieving target screening adherence rates for several cancers, including colorectal cancer (CRC). Providers were eligible for \$1,000 for achieving a 50 % adherence rate and an additional \$2,000 for achieving an 80 % adherence rate for all applicable tests. The primary objective of our study was to determine whether implementation of the performance incentive was associated with an increase in potentially inappropriate screening colonoscopy orders for patients with life expectancies <4 years. We also assessed whether providers with high rates of CRC screening adherence had a higher proportion of colonoscopy orders for patients with life expectancies <4 years vs. providers with low rates of screening adherence.

METHODS: Electronic records of visits with participating providers were queried for screening colonoscopy orders during the last year prior to the incentive program (pre-intervention period) and the first year of the incentive program (post-intervention period). Using a previously validated mortality prediction model, orders were classified as “inappropriate” if patients’ 4-year expected mortalities were >50 %. A chi-square test was conducted to compare the proportion of orders that were “inappropriate” during the pre-intervention period vs. the post-intervention period. A t-test was also performed comparing the mean risk scores of patients receiving colonoscopy orders during the pre-intervention period vs. the post-intervention period. Logistic and linear regressions were also performed, controlling for age, race, marital status, and gender. In a second analysis, we compared the proportion of “inappropriate” orders for providers with the highest and lowest proportion of screening colonoscopy orders (defined as the top 20 % and bottom 20 %), respectively.

RESULTS: The study population included screening colonoscopy orders for 1057 patients in the pre-intervention period and 1021 patients in the post-intervention period across 23 providers participating in the financial incentive. Patients were on average 58.03 years of age and 61 % were female. Only 0.6 % (n=6/1057) of

screening colonoscopy orders in the pre-intervention period and 0.6 % (n=6/1021) of screening colonoscopy orders in the post-intervention period were deemed “inappropriate.” There was no significant difference in the mean risk scores or the proportions of “inappropriate” orders between the pre- and post-intervention periods. Linear regression found no effect of time period upon risk score. There was no significant difference between the proportions of orders that were “inappropriate” among orders by high rate providers vs. low rate providers.

CONCLUSIONS: We found no evidence that a performance incentive based upon colonoscopy adherence rate led to a significant increase in inappropriate orders for screening colonoscopies. Our model is limited in that it only identifies orders that are inappropriate due to patients’ age, functional status, smoking, body mass index, and multiple comorbidities.

EFFECT OF THERAPEUTIC SUBSTITUTION ON MEDICATION RECONCILIATION AT HOSPITAL DISCHARGE Jessica S. Wang¹; Boback Ziaeian^{2,3}; Osama Abdelghany⁴; Robert L. Fogerty^{5,6}; Grace Jenq⁷; Sandhya V. Kanade⁶; Leora I. Horwitz^{5,8}. ¹Yale University School of Medicine, New Haven, CT; ²David Geffen School of Medicine at UCLA, Los Angeles, CA; ³Jonathan and Karin Fielding School of Public Health at UCLA, Los Angeles, CA; ⁴Yale-New Haven Hospital, New Haven, CT; ⁵Yale University School of Medicine, New Haven, CT; ⁶Yale-New Haven Hospital, New Haven, CT; ⁷Yale University School of Medicine, New Haven, CT; ⁸Yale-New Haven Hospital, New Haven, CT. (Tracking ID #1927862)

BACKGROUND: Although therapeutic substitution, or the substitution of a chemically different but therapeutically equivalent drug for the one originally prescribed, is widely used by hospitals to control inpatient pharmaceutical costs through hospital formularies, the impact of this practice on patients’ discharge medication regimens has not been adequately studied. We determined the frequency at which inpatient therapeutic substitution led to changes in discharge medications and assessed the extent to which it contributed to medication reconciliation errors.

METHODS: We analyzed data from the Diagnosing Systemic failures, Complexities and HARm in GEriatic discharges (DISCHARGE) study, a prospective, observational cohort study of patients 65 years or older admitted to a tertiary care hospital for acute coronary syndrome, heart failure, or pneumonia between May 2009 and April 2010 who were discharged home. We examined patients’ medications from six commonly substituted drug classes: proton pump inhibitors, H2 blockers, HMG-CoA reductase inhibitors, angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, and inhaled corticosteroids. The occurrence of therapeutic substitution was determined by comparing admission to inpatient medication lists. Medications that were changed to a different drug within the same class at discharge were noted by comparing admission to discharge medication lists. Any medication reconciliation changes at discharge that did not appear intentional based on review of the medical record were classified as suspected errors. We calculated the relative risk of a home medication being switched to a different drug within the same class at discharge among medications that were therapeutically substituted during the hospital stay compared to those that were not. We also calculated the relative risk of a medication reconciliation error between these two groups.

RESULTS: A total of 377 patients enrolled in the DISCHARGE study, collectively taking 2,583 admission medications. We analyzed the 555 (21.5 %) admission medications taken by 303 of the patients (80.4 %) that were within the six drug classes of interest. Of these, 244 (44.0 %) were therapeutically substituted during the hospitalization while the remaining medications were continued unchanged or were held for the duration of the hospital stay. Twenty-eight of the two hundred forty-four therapeutically substituted medications (11.5 %), as compared to 8 of the 311 non-therapeutically substituted drugs (2.6 %), were changed at discharge to a different medication within the same drug class as the patient’s original home medication (relative risk (RR) 4.46, 95 % confidence interval (CI) 2.07–9.61). A total of 41 (7.4 %) of the 555 medications of interest had a suspected medication reconciliation error at discharge. 28 (68.3 %) of these were medications that were therapeutically substituted while inpatient. Suspected medication reconciliation errors were more likely to occur among medications that had been therapeutically substituted than those that had not been (RR 2.75, 95 % CI 1.45–5.19).

CONCLUSIONS: Therapeutic substitution during hospitalization was associated with a significantly higher rate of suspected medication reconciliation errors at discharge as well as a considerable increase in changes to medication type at discharge. This creates a risk for patient misunderstanding and adverse drug events. In light of these findings, the widespread practice of therapeutic substitution may warrant reevaluation.

EFFECTIVENESS OF A BRIEF PEER SUPPORT INTERVENTION FOR VETERANS WITH CHRONIC PAIN Marianne S. Matthias; Alan B. McGuire; Marina Kukla; Joanne Dagg; Laura J. Myers; Matthew J. Bair. Roudebush VAMC, Indianapolis, IN. (*Tracking ID #1932711*)

BACKGROUND: Chronic pain is prevalent, disabling, and costly. Pain reduces quality of life and is associated with emotional distress when it interferes with work, social and recreational activities, and family life. This pilot study tested a peer support program, involving peer delivery of pain self-management strategies, for veterans with chronic pain.

METHODS: This was a pre-test/post-test design with a 4-month intervention period. Measures were administered at baseline and at 4 months. Ten peer coaches and 20 patients were recruited. All had chronic musculoskeletal pain. Peer coaches had participated in a prior chronic pain study involving pain self-management. Patients were recruited from a VA medical center and had at least moderate pain severity, defined by pain ≥ 5 on a 0 (no pain) to 10 (worst pain imaginable) scale. After a 3-hour training session, peer coaches were each assigned two patients. Coaches and patients were matched on age and pain location to the extent possible and were instructed to meet face-to-face or via phone biweekly for 4 months. Coaches and patients were given a study manual that included sections on chronic pain basics, activity pacing, relaxation skills, and self-care skills. Peer coaches were encouraged to discuss different topics, guided by the manual, at each meeting, as well as to work on goal setting and provide support, motivation, and encouragement as appropriate. Coaches participated in regular supervision calls, which reinforced training, taught additional motivational strategies, and provided a forum to discuss questions or concerns. Pain was the primary outcome and was assessed with the PEG, a 3-item version of the Brief Pain Inventory, and the PROMIS Pain Interference Questionnaire. The following secondary outcomes were assessed: depression (PHQ-9), anxiety (GAD-7), self-efficacy (Arthritis Self-Efficacy Scale), patient activation (PAM), perceived social support (Multi-Dimensional Perceived Social Support Scale), and two measures of negative pain cognitions: pain catastrophizing (Pain Catastrophizing Scale), and pain centrality (Centrality of Pain Scale). A linear mixed model with a random effect for peer coaches was applied to the change scores (post - pre measures). This accounts for the intra-class correlation (patients nested within peer coaches). Outcomes are reported for patients only.

RESULTS: Nine peer coaches and 17 patients completed the study. All were male veterans. Patients' ages ranged from 35 to 66 ($M=58$, $SD=8$) years. Peer coaches' ages ranged from 50 to 71 ($M=60$, $SD=7$) years. Patients' pain conditions were as follows: low back ($n=8$), neck (6), knees (1), shoulders (1), "everywhere" (1). Patients' pain improved but did not reach statistical significance ($p=.33$, $ICC=.28$, Cohen's $d=-.25$ for PEG; $p=.17$, $d=-.35$ for PROMIS). Depression showed little improvement ($p=.47$, $d=-.17$). Anxiety ($p=.11$, $d=-.36$), self-efficacy ($p=.16$, $ICC=.56$, $d=.60$), patient activation ($p=.12$, $ICC=.40$, $d=.49$), perceived social support ($p=.11$, $d=.37$), pain catastrophizing ($p=.12$, $d=-.42$), and centrality of pain ($p=.06$, $ICC=.32$, $d=-.62$) all improved.

CONCLUSIONS: This study suggests that peers can effectively deliver pain self-management strategies and support to other veterans with pain. Although this was a pilot study with a relatively short intervention period, patients showed improvement in several outcomes. In particular, effect sizes were moderate for improved self-efficacy, patient activation, and pain centrality. Although pain did not significantly improve, there was a modest change in the expected direction, suggesting that a longer intervention, which allows patients more time to adopt and benefit from the self-management strategies learned, may result in a larger effect on pain, as well as greater effects on psychosocial outcomes.

EFFECTIVENESS OF A HEART FAILURE EDUCATION INTERVENTION IN A LOW LITERACY PATIENT POPULATION Shing-Yu Lin; Lori Randall; Mary E. Wiles; Yoo Mee Shin; Michelle Edwards; Diane Wirth; Nurcan Ilksoy; Robin Klein. Emory University, Atlanta, GA. (*Tracking ID #1923870*)

BACKGROUND: High disease burden and low literacy among patients can make educational interventions important and challenging. The objective was to evaluate the effectiveness of a heart failure education intervention in a low literacy patient population.

METHODS: We conducted a prospective study to evaluate the effectiveness of a heart failure education intervention in a low literacy patient population. Patients completed a pretest prior to the education while inpatient and a subsequent posttest at follow-up clinic visit 1 to 2 weeks later. We included all adult inpatients with new or worsening heart failure newly referred to the Grady Heart Failure Program from November 2012 to April 2013. Outcomes included self-reported education level and employment status, knowledge of and confidence with heart failure self-management, and 30-day and 6 month readmissions.

RESULTS: Fifty-one patients agreed to participate and complete data including pretest and posttest was available for 34 patients. Heart failure education led to a significant increase in patients' mean knowledge scores (77.6 % to 82.8 %, $p=0.04$). Knowledge scores did not correlate with employment status or education level. Confidence scores increased significantly with the educational intervention. Highly confident patients had significantly higher knowledge scores than less confident patients on the pretest and posttest ($p=0.04$ and $p=0.01$ respectively). There was no significant difference in knowledge or confidence scores between patients readmitted within 30 days or 6 months of discharge and those not readmitted. There was an overall decrease in heart failure readmissions after the implementation of the heart failure program, including the education program.

CONCLUSIONS: Educational intervention geared towards a low literacy population is effective in improving patients' knowledge of and confidence with managing heart failure. This suggests there is benefit to expanding education programs in patient populations with low literacy and high disease burden.

EFFECTIVENESS OF TARGETED PHONE CALLS TO REDUCE NO-SHOWS IN A HOSPITAL-BASED PRIMARY CARE CLINIC: A RANDOMIZED CONTROLLED TRIAL Sachin J. Shah¹; Clemens S. Hong¹; Patrick R. Cronin²; Benjamin I. Bearnot¹; Calvin A. Richardson³; Blair W. Fosburgh¹; Alexandra Kimball⁴. ¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Massachusetts General Hospital, Boston, MA; ⁴Massachusetts General Hospital, Boston, MA. (*Tracking ID #1934774*)

BACKGROUND: "No-shows", or missed outpatient appointments, fragment continuity of care, effectively decrease access to primary care for all patients within the practice, and decrease productivity for primary care clinicians. Patient Service Coordinators (PSCs) are the first contact for patients with the office both in person and via phone or electronic communication. They schedule appointments, facilitate referrals, and perform outreach for patients overdue for appointments or screening tests and may be important sources of contact in preventing no-shows. We aimed to assess the effectiveness of a targeted phone call to a population predicted to be at high risk of "no-shows."

METHODS: We conducted a randomized controlled trial to reduce no-shows at the Internal Medicine Associates (IMA), a large, academic, hospital-based primary care practice staffed by 89 residents and 131 attending physicians. Approximately 320 patients visit the IMA daily. We included all patients older than 18 years old predicted to be at high risk to no-show for an appointment scheduled between April and October 2013. We estimated risk that a patient would no-show using a predictive model that included age, insurance status, prior history of no-shows, appointment type and wait days (days between the scheduling and appointment date) as predictors. We randomized high-risk patients (defined as those with >15 % absolute risk) to usual practice (control) or usual practice plus a phone call from a PSC (intervention) using their medical record number. To encourage patients to arrive for appointments, routine practice for the IMA is to mail a letter 2–6 weeks prior to the appointment and make an automated phone call 3 days prior to the appointment. Patients randomized to the intervention appeared in the queue of an online

calling tool 7 days prior to their appointment. PSCs completed calls in the queue daily and recorded outcomes of the call in the online calling tool. Patients would remain in the calling queue until the call was recorded as complete or until the date of their appointment passed. We trained PSC, over 4 weeks, to use the web-based calling tool in both group sessions and one-on-one sessions. PSCs also underwent a brief training in a conversational technique designed to engage patients in concrete planning. We instructed PSCs to remind the patient of the appointment, ask if they will make the appointment and problem solve any barriers that would prevent them from making the appointment. We compared our main outcomes: 1) no-show rate 2) percentage of cancelled appointments slots in which another patient was seen using chi-square test. We performed analyses on an intention-to-treat basis.

RESULTS: We randomized 4055 high-risk patients into intervention ($n=2117$) and usual practice ($n=1938$) groups. PSC completed 1622 of the 2117 (76.6 %) assigned calls prior to patients' appointments. In the intervention arm 325 (15.4 %) of 2117 patients no-showed for their appointment, and in the control arm 395 (20.4 %) of 1938 patients no-showed for their appointment (RR 0.75; 95 % CI 0.66–0.86; $p<0.001$). The percent of canceled appointment slots in which another patient was scheduled and seen, was no different between the intervention and control groups (24.4 % vs 22.6 %, respectively; RR 1.08; 95 % CI, 0.87–1.33; $p=0.48$).

CONCLUSIONS: A targeted program of phone calls from a patient service coordinator designed to engage the patient in concrete planning significantly reduced no-show rates among patients at high risk for no-shows. However, when appointments were canceled, the intervention did not lead to a significantly higher rate of successfully rescheduled appointments. Phone interventions designed to address barriers and reduce no-shows among patients at high-risk, may reduce no-show rates while improving continuity of care, access to primary care, and productivity for primary care clinicians.

EFFECTIVENESS OF USING NON-CLINICIANS IN DELIVERING A BRIEF SMOKING CESSATION INTERVENTION IN THE EMERGENCY DEPARTMENT

Ellie Grossman¹, Maria I. Duenas¹, Ashley Colucci²; Renee Fruchter³; Binhan Wang³. ¹New York University, New York, NY; ²New York University, New York, NY; ³New York University, New York, NY. (Tracking ID #1937034)

BACKGROUND: Tobacco remains a leading preventable cause of morbidity and mortality. Prior studies have shown that Emergency Department (ED) patients typically smoke at rates exceeding that of the general population, are interested in quitting, and often have limited access to primary care. However, a busy ED can be a difficult setting to implement preventive-health interventions. In this study, we describe a pilot initiative using non-clinician volunteers to deliver a brief smoking cessation intervention to ED patients who smoke. We focused on providing minimal counseling in the ED and instead encouraging post-visit Quitline contact for high-quality telephone counseling and delivery of cessation medication.

METHODS: We trained a cohort of college-aged volunteers to assess adult patients for use of tobacco products in the Bellevue Hospital ED and proactively refer interested smokers to the NYS Quitline. All patients were offered printed information about resources to help them quit smoking. We collected information about the number of patients approached, the number who reported using tobacco and nicotine products, and acceptance of referral to the NYS Quitline. We collected follow-up reports from the NYS Quitline and also attempted to contact all smokers at least once via phone approximately 1 month after ED visit. These follow-up reports provided information about use of smoking cessation pharmacotherapy, quit attempts, and smoking status. We performed bivariable and multivariable analyses to explore for predictors of quitline referral, successful access of quitline services, and smoking status at 1 month follow-up.

RESULTS: During the two-month intervention period in summer 2013, we screened 1619 adult patients for tobacco use. 428 (26.4 %) had smoked a

cigarette in the past 30 days. Mean age was 42.6 years (SD 12.4), and 72 % were male. English (85 %) and Spanish (8 %) were the preferred languages. Other nicotine product use in the past 30 days included electronic cigarettes (8.3 %), cigars (4.6 %), and pipes (1.7 %). Among cigarette users, 40 % reported smoking <5 cigarettes/day, 32 % 5–10 cigarettes/day, 21 % 11–20 cigarettes/day, 5 % 21–30 cigarettes/day, and 3 % >30 cigarettes/day. Two-hundred fifty patients accepted a flyer with information about quit-smoking resources, and 139 (56 % of the smokers with phones) agreed to participate in the Quitline proactive outreach program. The NYS Quitline reported follow-up data for 99 patients, and of these, 25 (25 %) had completed a Quitline telephone encounter. The NYS Quitline reported that 15 (60 %) had already quit smoking, 9 (36 %) wanted to quit smoking, and 2 (8 %) were not ready to quit yet. Our program reached 78 patients for 1-month follow-up, and 25 (32 %) reported abstinence from tobacco for the previous 7 days. Forty-five patients (58 %) reported a quit attempt lasting longer than 24 h since their ED visit, and 11 (14 %) had used a smoking cessation medication. Smokers who smoked more cigarettes per day (11–20 as compared to <5) were more likely to accept quitline referral (OR 2.53, 95 % CI 1.16–5.53); there were no significant associations between age, gender, language, or e-cigarette use and acceptance of quitline referral. Non-English speakers were more likely than English speakers to successfully complete a Quitline outreach call (OR 3.07, 95%CI 1.00–9.42, $p=.05$). There were no significant associations between age, gender, use of e-cigarettes, or amount of cigarettes smoked and likelihood of successful contact by Quitline. At one-month follow-up, participants who reported smoking 5–20 cigarettes/day at baseline were less likely to have quit than those smoking <5 cigarettes/day ($p<.05$).

CONCLUSIONS: Trained volunteers are able to deliver a brief smoking cessation intervention in the ED and can feasibly refer patients to the Quitline. This brief intervention, consistent with evidence-based guidelines for tobacco dependence treatment, is acceptable to patients undergoing treatment in a busy urban safety-net hospital ED.

EFFECTS OF 2010 ACGME REGULATIONS ON INTERNAL MEDICINE RESIDENCY PROGRAMS IN THE NORTHEAST

Omar Mousa; Rushikesh Shah; Samana Zaidi; Amit S. Dhamoon. SUNY - Upstate Medical University, Syracuse, NY. (Tracking ID #1939563)

BACKGROUND: To study the variables that influence the perceptions of the 2010 Accreditation Council for Graduate Medical Education (ACGME) work hour regulations (WHR) by the housestaff (HS), program directors (PD) and faculty physicians (FP) within the residency training programs of internal medicine.

METHODS: An online questionnaire was distributed among 131 residency training programs in the northeast of the US. Study subjects included the HS, PD and FP in the department of internal medicine. Questionnaires were completed anonymously. Our endpoint focused on analysis of the variables that influence how the 2010 ACGME/WHRS are perceived by HS, PD and FP. Data analysis was conducted using SPSS Statistics v19.

RESULTS: 203 internal medicine HS, PD and FP were included (158 residents, 24 FP, 11 PD). 87.2 % were of ages 20–40 years; 57.1 % Males; 41.9 % US medical graduates (US-MG). Many respondents agreed that the 2010 ACGME/WHR negatively affected the continuity of patient care (48.8 %), and had a positive impact on the residents' quality of life while not at work (69 %). Among the different levels of training, there was a significant difference in the perceptions regarding patient care ($p<0.05$), residency education ($p=0.004$) and continuity of care ($p=0.001$). Those of ages >40 years feel that residency education and the care of patients is impacted adversely ($p=0.012$) compared to their younger colleagues. The younger age groups (<=40 years) were more likely to feel that their programs do not strictly follow the ACGME regulations ($p=0.016$). However, they were more satisfied with the rules ($p=0.033$). Compared to international medical graduates (IMG), the US-MGs believe more that residency education (36.5 % vs 28 %) and patient care (40 % vs 30.5 %) worsened. More US-MGs believe that the continuity of care is affected ($p=0.016$).

0.011). 58.1 % feel that the residents and interns work under pressure to leave the hospital on time due to the WHRs. Higher rates of IMGs (51.7 %) feel that residents do not work under pressure to leave the hospital on time, while 71.8 % of the US-MG feel that they do ($p = 0.001$). Satisfaction among HS, PD and FP is significantly variable ($p = 0.003$).

CONCLUSIONS: The 2010 ACGME WHRs were implemented to enhance patient safety by improving the quality of life of the resident. Several unintended consequences of this change, including difficulties with continuity of care, patient safety, and residency education have resulted. The perception of these changes is influenced by the age, gender, and previous medical training of the respondents to our survey. These variables should be addressed by the ACGME when future changes to the resident work hour regulations are made. Such changes have a great impact on the current clinical practice.

EFFECTS OF MINIMAL VS. INTENSIVE INTERVENTION TO ENHANCE MOTIVATIONAL INTERVIEWING IN HIV CARE Mary Catherine Beach¹; Michael B. Laws²; Gary S. Rose¹; Debra L. Roter¹; Richard D. Moore¹; Geetanjali Chander¹; Ira Wilson². ¹Johns Hopkins University, Baltimore, MD; ²Brown University School of Public Health, Providence, MA. (*Tracking ID #1938857*)

BACKGROUND: Behavior change counseling has become an essential component of primary care, but many clinicians lack the skills to counsel patients effectively. Motivational interviewing (MI), a client-centered counseling method of eliciting motivation for change, has been widely endorsed as a framework for clinicians to use in counseling patients. MI may be particularly helpful for clinicians providing HIV care, who counsel patients frequently on issues such as adherence, safe sex, and substance use treatment. As MI programs are rolled out, it is important to evaluate how to efficiently and effectively deliver MI training to busy clinicians. We conducted a randomized trial comparing the effect of two different levels of MI training on clinician communication behaviors and patient experiences.

METHODS: We enrolled 12 HIV clinicians (eight physicians, three nurse practitioners, and one physician assistant) at a single academic medical center. All clinicians attended a one-day workshop with an experienced MI trainer, focusing on behavior change counseling skills. After the workshop, we randomized clinicians to receive (or not) 3 to 5 rounds of personalized one-on-one feedback from the MI trainer, using audio-recordings of the clinician's own visits with patients as the basis for feedback. We measured clinicians' attitudes towards and use of MI counseling techniques at baseline and again after completion of the intervention. We also administered post-visit Healthcare Climate Questionnaires assessing patient perceptions of the degree to which the clinician adhered to the spirit of MI. Audio recordings were analyzed using the Roter Interaction Analysis System to evaluate MI-consistent communication behaviors. We compared outcome measures before and after the interventions and between the two intervention groups (workshop alone vs. workshop plus feedback). To assess whether one intervention was more effective than the other, we tested time-by-study arm interactions to determine whether one group improved more than the other. For all analyses, we used generalized estimating equations to account for clustering of patients within clinicians, with Gaussian or negative binomial distributions as appropriate.

RESULTS: Clinicians in both intervention groups reported greater use of MI-consistent behaviors after vs. before the intervention, without differences between groups in the magnitude of the effect. Patients also rated their visits as more MI consistent (6.86 vs. 6.65, $p=0.004$), and audio recorded analysis revealed that visits were more patient-centered (1.34 vs. 0.96, $p=0.003$), with a more positive

patient affect (22.36 vs. 20.84, $p<0.001$), after vs. before the intervention, without differences between intervention groups. Analysis of audio-recorded visits revealed increases in clinician behaviors such as empathic statements and asking patient permission, and reductions in disapproval, after vs. before the intervention, again without differences by intervention group. Some clinician behaviors such as asking patient opinions and the ratio of open to closed-ended questions improved to a greater extent in the workshop plus feedback vs. the workshop only intervention arm.

CONCLUSIONS: The workshop alone was as effective as the workshop plus feedback intervention in improving patient experiences and overall communication measures. Certain communication behaviors improved to a greater extent with the more intensive intervention, but these additional improvements may not be substantial enough to warrant the extra financial and logistical resources required.

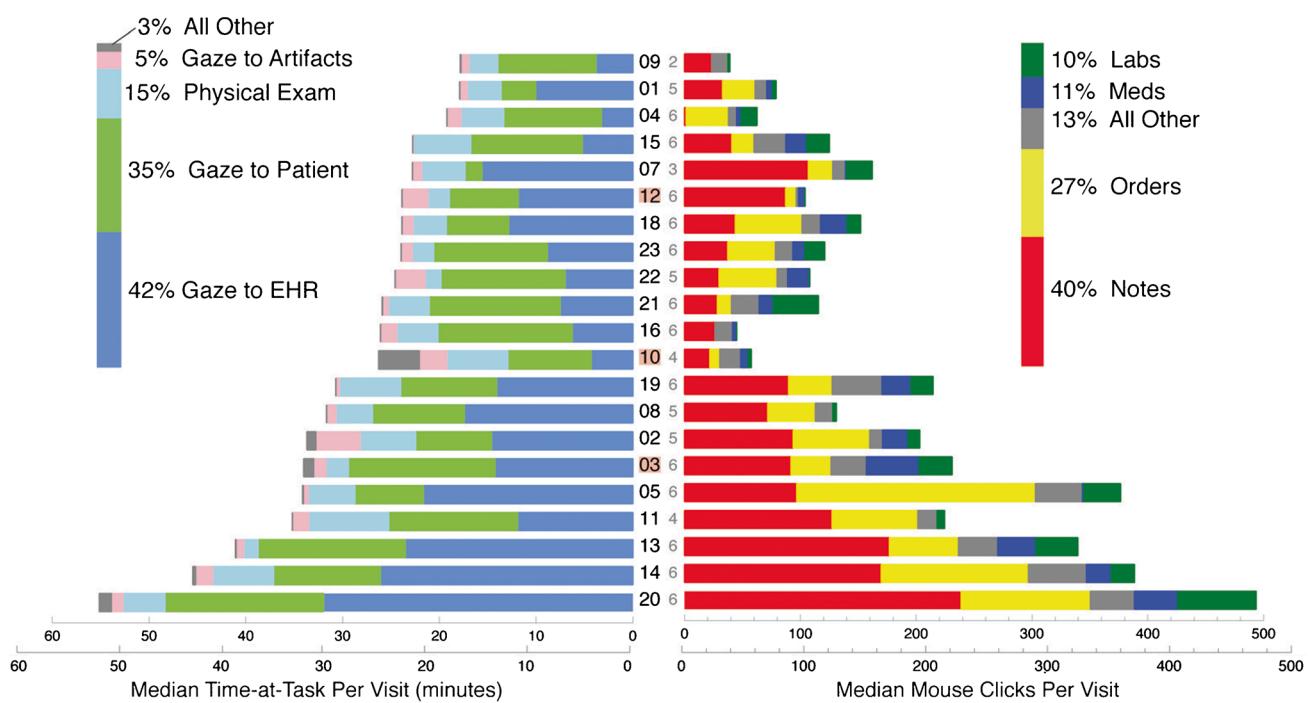

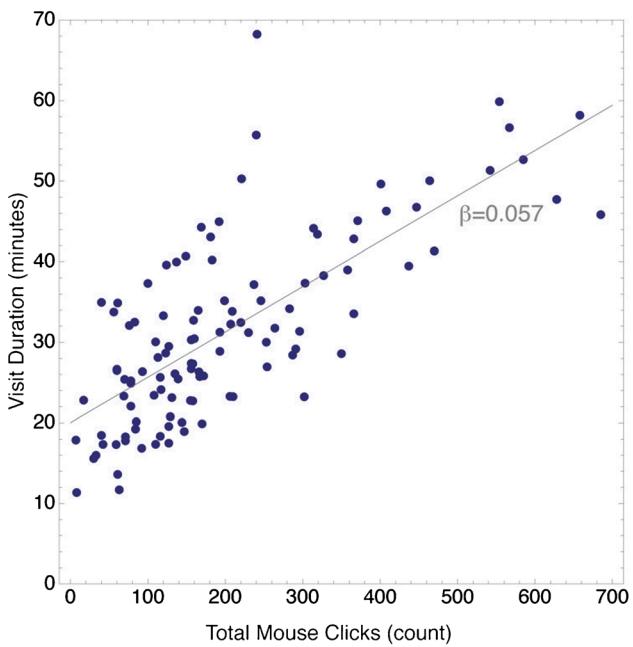

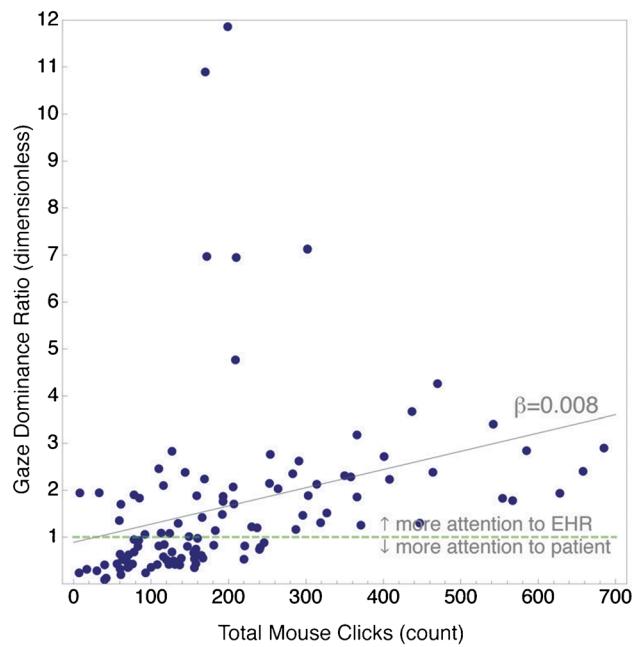

EHR USABILITY BURDEN AND ITS IMPACT ON PRIMARY CARE PROVIDERS WORKFLOW Zia Agha^{1,2}; Alan Calvitti³; Shazia Ashfaq³; Neil J. Farber²; Richard L. Street⁴; Kristin Bell¹; Lin Liu¹; Mark Gabuzda¹; Yunan Chen⁵; Barbara Gray³; Steven Rick³. ¹VA San Diego Healthcare System, San Diego, CA; ²Univ. of California San Diego, San Diego, CA; ³Veterans Medical Research Foundation San Diego, San Diego, CA; ⁴Texas A&M, College Station, TX; ⁵Univ. of California Irvine, Irvine, CA. (*Tracking ID #1940994*)

BACKGROUND: Electronic Health Records (EHRs) often integrate poorly with clinical workflow and suffer from poor usability. In this paper, we describe how primary care clinicians' EHR use patterns relate to usability and how these patterns suggest multiple inefficiencies and burdensome workflow for primary care providers.

METHODS: This time-motion study is based on video and EHR activity capture. We observed 21 clinicians and 111 established patients during primary care office visits at 4 Veterans Administration (VA) clinics. Data were coded for specific EHR tasks and clinical workflow. Hierarchical and sequential analysis of EHR clickstream and clinical workflow were integrated to provide objective baseline use patterns.

RESULTS: The 111 outpatient follow-up visits (~60 h of observation) were analyzed in terms of time-at-task in clinical workflow (Figure 1A). Clinicians spent 42 % of visit time with EHR tasks compared to 35 % with patients. We observed a median 158 mouse clicks per visit and for every 100 mouse clicks (Fig 1B), visit duration increases by 6 min (95 % CI=0.05–0.07, $p<0.0001$). Clinicians frequently multitask when using EHRs and navigate across multiple functions (median 19 times per visit). Notes (40 %) and Orders (27 %) were the most frequently used functions. Menu and form driven functions like Consultation (15.8 clicks/unit), imaging (14.5 clicks/unit), and medication orders (9.4 clicks/unit) required burdensome user input.

CONCLUSIONS: EHR activity consumes a majority of visit time and shifts the clinician's focus away from the patient. EHRs also introduce multitasking, which has been associated with medical errors, clinician dissatisfaction, and missed opportunities for physician-patient communication. While some time-and-motion studies have reported little or no change in visit duration for EHR-based versus paper-based visits, we observed that higher EHR activity is associated with longer visits. These associations while not conclusive, provide partial validation of physicians' concerns that poorly designed and implemented EHRs can lower clinical productivity. Our study highlights unintended inefficiencies introduced in clinical work due to poorly designed EHR user interfaces and emphasizes the need to address EHR usability as a key area for improvement to support meaningful use.

ELECTRONIC HEALTH RECORDS IMPROVE CLINICAL NOTE QUALITY Harry B. Burke¹; Albert Hoang¹; Dorothy Becher¹; Paul Fontelo²; Ronald W. Gimbel¹. ¹Uniformed Services University of the Health Sciences, Bethesda, MD; ²National Library of Medicine, Bethesda, MD. (*Tracking ID #1938123*)

BACKGROUND: Electronic health records (EHR) are being adopted throughout the United States yet it is not known whether they improve the quality of clinical notes. We hypothesized that electronic health records would improve the quality of clinical notes.

METHODS: This five and one-half year blinded longitudinal, retrospective multicenter study compared the quality of handwritten and electronic outpatient clinical notes for the same cohort of 100 patients with type II diabetes mellitus at three time points: 6 months prior to the introduction of the EHR (before-EHR), 6 months after the introduction of the EHR (after-EHR), and 5 years after the introduction of the EHR (5-years-EHR). QNOTE is a quantitative validated instrument that assesses the quality of outpatient clinical notes. (JAMIA online 1/2/14) Its 12 evaluative elements are: chief complaint, history of present illness, problem list, past medical history, medications, adverse drug reactions & allergies, social & family history, review of systems, physical findings, assessment, plan of care, and follow-up information. QNOTE scores can range from a low of 0 to a high of 100. Sixteen primary care physicians with active practices used QNOTE to determine the quality of the 300 clinical notes (100 patients with 3 notes each).

RESULTS: All 12 element quality scores significantly improved in the interval between before-EHR and 5-years-EHR. The grand mean QNOTE scores were: 6 months before the introduction of the EHR (handwritten), 52.0 (SD 18.4), 6 months after EHR, 61.2 (SD 16.3), and 5 years after EHR, 80.4 (SD 8.9). The grand mean QNOTE scores significantly improved after the introduction of the EHR, comparing before-EHR to after-EHR, $p<0.0001$, and before-EHR to 5-years-EHR, $p<0.0001$.

CONCLUSIONS: The introduction of the electronic health record significantly improved the quality of clinical notes.

QNOTE scores (mean, SD)

Elements	Before-EHR	5-years-EHR	Before vs. 5-years
Chief complaint	62.5 (28.3)	78.2 (23.7)	25 % (<0.0001)
History of present illness	63.2 (26.1)	84.7 (18.3)	34 % (<0.0001)
Problem list	24.0 (28.9)	59.6 (31.2)	144 % (<0.0001)
Past medical history	29.4 (36.4)	84.7 (24.0)	188 % (<0.0001)
Medications	59.0 (39.0)	90.8 (17.7)	54 % (<0.0001)
Drug reaction & allergies	69.1 (33.7)	79.3 (29.4)	15 % (<0.05)
Social & family history	25.4 (27.9)	72.7 (26.0)	186 % (<0.0001)
Review of systems	30.7 (33.3)	80.4 (23.8)	162 % (<0.0001)
Physical findings	66.3 (27.6)	85.8 (16.5)	29 % (<0.0001)
Assessment	65.5 (24.4)	86.6 (14.5)	32 % (<0.0001)
Plan of care	65.4 (24.6)	85.3 (15.3)	31 % (<0.0001)
Follow-up information	63.5 (27.0)	81.7 (20.5)	29 % (<0.0001)
Grand mean	52.0 (18.4)	80.4 (8.9)	55 % (<0.0001)

ELECTRONIC RESOURCE USE AND PRIMARY CARE CAPACITY AS INSURANCE COVERAGE EXPANDS Renuka Tipirneni^{1,2}; Hwajung Choi^{1,2}; Matthew M. Davis^{3,1}. ¹University of Michigan, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI; ³University of Michigan, Ann Arbor, MI. (*Tracking ID #1934522*)

BACKGROUND: As millions of Americans gain health insurance coverage offered by the Patient Protection and Affordable Care Act (ACA), newly insured individuals will face the challenge of finding a primary care physician (PCP). Given the limited supply of PCPs in the U.S., state and local health planners must consider how to increase PCPs' capacity to accept new patients. Use of electronic resources, or "meaningful use", has been widely viewed as providing potential savings in practice costs and time. However, it remains unclear whether electronic resource use can improve practice efficiency and, ultimately, expand capacity of primary care physicians to accept the newly insured into their panels. We examine whether increased use of electronic resources is associated with change in primary care capacity.

METHODS: We analyzed data from the Center for Healthcare Research & Transformation 2012 Survey of Michigan Physicians, a cross-sectional survey of Michigan PCPs conducted between October and December 2012. Surveys were mailed to 1500 PCPs, 500 from each of three specialties (pediatrics, internal medicine and family medicine). Survey items included questions about the primary predictor variable, PCPs' use of electronic resources; this variable was operationalized for each

of several resources individually (electronic health records, patient registry, electronic prescribing, web portal for appointment scheduling or prescription refills, reminder system, care improvement registry and electronic access to admitting hospital records) and in aggregate (total count of electronic resources in use). The primary outcome was PCPs' assessment of their future capacity (yes/no) to accept new patients overall, and by payer (e.g. private insurance, Medicaid, and Medicare). We conducted bivariate analyses between primary predictors and outcomes. We then performed multivariable logistic regression analysis to examine the relationship between use of electronic resources and primary care capacity, after controlling for physician characteristics (gender, specialty, number of years in practice, panel volume; all by self-report), practice factors (practice size, current insurance payer mix; all by self-report), and urbanicity of the PCPs' practice setting (urban vs. suburban vs. rural county; by linking Federal Information Processing Standard county codes obtained from self-reported zip code to the U.S. Department of Agriculture Economic Research Service 2013 Urban Influence Codes).

RESULTS: The study sample included 739 physicians (response rate = 49 %). Overall, 83 % of PCPs reported they would have capacity to accept new patients in the future. The most common electronic resource in use at the time of the survey was electronic prescribing (89 % of PCPs); the least common resource in use was a web portal for patients to schedule their own appointments (21 %). In aggregate, PCPs had a mean of 5.1 electronic resources in their practices. In bivariate analyses, with each incremental increase in the number of electronic resources in use, there were significantly lower odds of future primary care capacity ($OR=0.87$, 95%CI 0.78–0.97). After adjusting for physician-, practice- and community-level covariates, incrementally greater numbers of electronic resources in use remained significantly inversely associated with anticipated capacity (adjusted $OR=0.86$, 95%CI 0.76–0.97). Among individual electronic resources examined, electronic health records (EHR) were the only resource significantly associated with anticipated capacity (adjusted $OR 0.53$, 95%CI 0.30–0.94). In analyses of future capacity by payer type, increased use of electronic resources overall (adjusted $OR=0.87$, 95%CI 0.77–0.98), and use of EHR specifically (adjusted $OR=0.50$, 95%CI 0.29–0.88), were associated with significantly decreased capacity to accept privately insured patients. There were no associations with future capacity to accept Medicaid or Medicare patients.

CONCLUSIONS: In this study of primary care capacity in a large state in the era of insurance coverage expansion, PCPs who were most likely to implement EHR and use a greater number of electronic resources were significantly less likely to accept new patients. The implication of these findings for patients obtaining coverage under the ACA is that access to primary care may be somewhat impeded, rather than facilitated, by factors associated with electronic resource implementation.

ELEMENTS OF TEAM-BASED CARE IN A PATIENT-CENTERED MEDICAL HOME ARE ASSOCIATED WITH LOWER BURNOUT AMONG VA PRIMARY CARE EMPLOYEES Christian Helfrich¹; Joseph Simonetti¹; Robert Reid⁶; Sandra Joos³; Bonnie J. Wakefield⁴; Ian A. Randall¹; Gordon Schectman⁵; Richard Stark⁵; Stephan D. Fihn^{2,1}; Henry B. Harvey¹; Karin M. Nelson¹. ¹VA Puget Sound Health Care System, Seattle, WA; ²Veterans Health Administration, Seattle, WA; ³Department of Veterans Affairs, Portland, OR; ⁴Department of Veterans Affairs, Iowa City, IA; ⁵Veterans Health Administration, Washington, DC; ⁶Group Health, Seattle, WA. (*Tracking ID #1938477*)

BACKGROUND: A high proportion of the US primary care workforce reports burnout, which is associated with negative consequences for clinicians and patients. Many protective factors from burnout are characteristics of patient-centered medical home (PCMH) models, though even positive organizational transformation is often stressful. The existing literature on the effects of PCMH on burnout is limited, with most findings based on small-scale demonstration projects with data collected only among physicians, and the results are mixed. To determine if components of PCMH related to team-based care were associated with lower burnout among primary care team members participating in a national medical home transformation, the VA Patient Aligned Care Team (PACT).

METHODS: We conducted a web-based, cross-sectional survey linked to administrative data from May 2012. A total of 4,539 VA primary care personnel from 588 VA primary care clinics. The dependent variable was burn-out, and the independent variables were measures of team-based care: team functioning, time spent in huddles, team staffing, delegation of clinical responsibilities, working to top of competency, and collective self-efficacy. We also included administrative measures of workload and patient comorbidity.

RESULTS: Overall, 39 % of respondents reported burnout. Participatory decision making (OR 0.65, 95 % CI 0.57, 0.74) and having a fully staffed PACT (OR 0.79, 95 % CI 0.68, 0.93) were associated with lower burnout, while being assigned to a PACT (OR 1.46, 95 % CI 1.11, 1.93), spending time on work someone with less

training could do (OR 1.29, 95 % CI 1.07, 1.57) and a stressful, fast-moving work environment (OR 4.33, 95 % CI 3.78, 4.96) were associated with higher burnout. Longer tenure and occupation were also correlated with burnout. Neither spending time on work for which one has too little training, nor measures of workload were associated with burnout.

CONCLUSIONS: Lower burnout may be achieved by medical home models that are appropriately staffed, emphasize participatory decision making, and increase the proportion of time team members spend working to the top of their competency level. Ensuring that primary care team members are tasked with appropriately challenging work appears to be a greater issue for burnout than work that exceeds one's training or the overall workload.

EMPATHY, CAREER INTERESTS, AND FACTORS INFLUENCING CAREER CHOICE AMONG MEDICAL STUDENTS Emma C. Jeffries; Charlotte E. Ward; Marya J. Cohen. Massachusetts General Hospital, Boston, MA. (*Tracking ID #1938468*)

BACKGROUND: An initial study indicates that high levels of physician empathy correlate with positive patient outcomes. However, in previous literature, medical student empathy scores have been shown to drop over the course of education despite increasing exposure to patient care, particularly in the inpatient setting. Empathy scores in students exposed to mentorship, educational opportunities, and longitudinal patient care in the outpatient setting have not been studied. At the Crimson Care Collaborative (CCC), five student-faculty collaborative practices across the Harvard teaching hospitals, students have the opportunity to care for and develop long-term relationships with primary care patients. Our goal was to examine the relationship between student empathy, future career interests, and factors influencing career choice.

METHODS: Prior to joining CCC, Harvard Medical School (HMS) students completed a survey about career interests, and factors important in career choice. Empathy was evaluated using the Jefferson Empathy Scale, a validated 20-question survey. A single empathy composite score was then generated for each respondent. The relationship between career interest and career choice factors, and empathy, was assessed using generalized linear models, controlling for year in medical school, gender, race, marital status, undergraduate major (science vs. non-science vs. both), and hometown type (rural vs. urban vs. suburban).

RESULTS: The study population included 166 students who completed both an initial survey and the Jefferson Empathy Scale. The average score was 118.8 (range 89–140). Out of 166 students, 75 % were first year medical students, 59 % were female, 60 % were white, and the average age was 25. Students who were interested in general medicine had a higher empathy score than those who were not (120.3 vs. 114.8; $p=0.04$). Students who prioritized working with the under-served had higher empathy scores than those who did not (120.5 vs. 114; $p=0.0003$). Students who prioritized future income had a lower empathy score than those who did not (117.4 vs. 120.2; $p=0.004$). Students who prioritized the ability to work part-time had higher empathy scores than those who did not (122 vs. 117.3; $p=0.02$). Students who wanted to teach students and residents had higher empathy scores than those who did not (120 vs. 115.8; $p=0.0003$).

CONCLUSIONS: Among medical students participating in a student-faculty collaborative practice, higher empathy scores were correlated with interest in general medicine, working with the under-served, the ability to work part-time, and teaching. The importance of income was negatively correlated with empathy score. In the future, we hope to examine empathy scores of students before and after participation in the Crimson Care Collaborative. Further research is needed on the extent to which empathy levels can be changed in medical students and what experiences might influence empathy levels. Findings around empathy and career choice may have implications for medical school admissions and primary care recruitment.

EMR-BASED PHYSICAL ACTIVITY COUNSELING AND REFERRAL IN PRIMARY CARE: AN EVALUATION STUDY Julien J. Dedier¹; Julie A. Wright²; Timothy Heeren³; Robert H. Friedman¹. ¹Boston University, Boston, MA; ²University of Massachusetts, Boston, MA; ³Boston University, Boston, MA. (*Tracking ID #1939345*)

BACKGROUND: Physical activity (PA) is beneficial in the prevention and management of several diseases, and linking primary care patients to effective PA programs may improve health outcomes for exercise-responsive conditions such as diabetes, hypertension and obesity. The purpose of this study was to evaluate the implementation of an electronic medical record (EMR) tool designed to help primary care providers conduct PA counseling and refer patients to an automated telephone PA coach.

METHODS: Content of the EMR PA tool was based on the 5A's approach to PA counseling and elements of motivational interviewing. Providers reviewed a prototype of the tool, and their feedback was used to design the final version. The tool was publicized at business meetings and by e-mail announcements. Providers could use the tool to do 1 or more of the following: (1) determine the patient's current level of PA and motivation to increase PA, and counsel accordingly; (2) create an exercise prescription; and (3) refer patients to use an automated telephone PA coach (TLC-PA). TLC-PA was developed by our group, and was shown to significantly increase self-reported PA of moderate-or-greater intensity in an RCT of hypertensive primary care patients. Patients referred to TLC-PA were scheduled to receive 12 weekly calls of roughly 10 min each. We collected implementation information from providers and patients. We captured the electronic footprint providers created whenever they used the tool, and surveyed users' opinions of the tool each time they used a new feature. We surveyed a random subset of non-users to determine their reasons for non-use. We also surveyed patients who were referred to TLC-PA on their impressions of the referral encounter.

RESULTS: 50 unique providers accessed the EMR tool at least once and were sent a survey about its functions. Of respondents ($n=13$), most agreed or strongly agreed the 3 EMR tool functions were easy to use (66 %–88 %), increased the quality of PA counseling they provided (72 %–88 %), were worth the time spent to use them (57 %–75 %), and should be made a permanent part of the EMR (82 %–100 %). Providers accessed the exercise prescription function most often (104 instances), then the stage-based counseling function (62 instances), followed by the TLC-PA referral function (36 instances). Providers' greatest reservation about PA referral was not knowing enough about the Coach to confidently refer their patients. Among non-user survey respondents ($n=24$), only 37.5 % had heard of the EMR PA tool. Ninety-two percent were not sure how to access it. Seventy-eight percent of patients selected for exercise counseling or referral had an exercise-responsive diagnosis of obesity, DM, PVD, or CAD. Fourteen of the 36 patients referred to use TLC-PA completed a survey about the office referral encounter. All recalled discussing PA and TLC-PA, and 86 % recalled receiving printed information about TLC-PA. All referred patients went on to use TLC-PA.

CONCLUSIONS: PA interventions such as our automated PA coach have been shown to increase PA. We successfully linked a PA counseling and referral intervention to the EMR. Primary care providers and their patients considered it helpful, but low-intensity advertising of the tool resulted in only modest use. Comprehensive implementation efforts are required to fully assess the feasibility of linking PA interventions to the EMR in primary care settings.

ENGAGING VETERANS IN CONVERSATIONS ABOUT HEALTH: A COMMUNITY PARTNERSHIP AND ASSESSMENT TO PROMOTE VETERAN HEALTH Anita D. Misra-Hebert^{1,2}; Laura Santurri³; Richard DeChant⁴; Brook Watts⁵; David Aron⁵. ¹Cleveland Clinic, Cleveland, OH; ²Louis Stokes Cleveland Veterans Affairs Medical Center, Cleveland, OH; ³Weber State University, Ogden, UT; ⁴Cuyahoga Community College, Cleveland, OH; ⁵Louis Stokes Cleveland Veterans Affairs Medical Center, Cleveland, OH. (*Tracking ID #1923869*)

BACKGROUND: As veterans of recent conflicts in Iraq and Afghanistan return to civilian life, and as veterans of previous conflicts continue to age, the importance of health promotion as related to chronic disease prevention and management in the veteran population will be a required area of focus for clinical providers. The high prevalence of mental health disease in veterans of recent military conflicts may affect risk for chronic disease development and the self-efficacy/coping mechanisms required for optimal chronic disease management. Veteran students pursuing higher education may be particularly motivated to engage in health promotion. The study objective is to explore motivations to improve health and to assess health among student veterans, using a shared forum, through partnership between a Veterans Affairs (VA) medical center and a community college.

METHODS: This study utilized a sequential mixed methodological design with an equally weighted approach for the qualitative and quantitative portions. The study participants were student veterans enrolled at a community college in October 2012–April 2013. Veteran students were recruited to participate in focus groups. Participants discussed views of health, motivations to improve health, and perceptions of medical care. Discussions were audio-recorded and transcribed. Other students then participated in a cross-sectional health assessment survey. Qualitative data analysis utilized a conventional content analysis approach to coding and thematic development. Survey data analysis included descriptive and logistic regression analyses.

RESULTS: A total of 17 veteran students participated in 6 focus groups. Emergent themes included changing views of health after transition from active duty, generational differences among veterans, barriers to accessing health services, and health care costs. Concerns about basic needs such as job/ housing and providing/

caring for family, stigma and privacy, and preferences related to health communication were also important themes. The motivation to improve health for many of our study participants was perceived as secondary to the need to obtain stable housing or work, and concerns about privacy and stigma were identified as possible barriers to seeking healthcare. Two hundred four students (21 % response rate) participated in the health assessment survey. Physical and emotional limitations (45 % and 35 %, respectively), and pain interfering with work (42 %) were reported. Self-reported depression and unhealthy behaviors were high.

CONCLUSIONS: Engaging veteran students in conversations about health and conducting a health assessment survey identified factors influencing motivation to improve health and priority areas to inform interventions for chronic disease prevention. The impact of social determinants on health is substantial in this group. A significant proportion of student veterans are limited in daily activities as a result of physical as well as emotional issues and specifically from pain. A partnership between a VA medical center and a community college integrates primary care with public health as a step to improving the health of veteran students in the community.

ENGAGING YOUTH THROUGH A SPOKEN WORD TYPE 2 DIABETES PREVENTION SOCIAL MARKETING CAMPAIGN Elizabeth A. Rogers^{1,2}; Sarah Fine⁴; Margaret A. Handley^{3,4}; Purba Chatterjee⁴; James Kass⁵; Dean Schillinger^{3,4}. ¹University of Minnesota, Minneapolis, MN; ²University of Minnesota, Minneapolis, MN; ³University of California San Francisco, San Francisco, CA; ⁴University of California San Francisco, San Francisco, CA; ⁵Youth Speaks, San Francisco, CA. (*Tracking ID #1939606*)

BACKGROUND: Type 2 diabetes (DM2) prevalence is rising among minority young adults. There is an unmet need to engage youth in identifying solutions to decrease this risk. Some media campaigns such as the successful truth® antismoking campaign used a socio-environmental perspective to shift social norms, and this approach may be one avenue toward engagement around DM2. Objective: To evaluate the effectiveness and reach of The Bigger Picture, a youth-generated, youth-targeted DM2 prevention social marketing campaign.

METHODS: Campaign Development: Through a partnership between UCSF and Youth Speaks, a youth spoken-word nonprofit, we used a participatory approach engaging youth poets to create 11 video public service announcements (PSAs) addressing the socio-environmental conditions that increase DM2 risk. Our dissemination focus was regional low-income and minority-serving high schools identified through collaboration with school districts, and we developed a scripted assembly and a writing workshop. We created a campaign website (www.thebiggerpicture.org) with information, PSA videos, and informational toolkit, and used Facebook and Twitter social media. Evaluation: Using the RE-AIM framework, we evaluated the campaign through efficacy measures capturing changes in knowledge and attitude, and those that characterized the reach of the campaign. We gathered data using audience response system handheld devices distributed to students (up to 80 per assembly) to answer 3 questions gauging knowledge and attitude embedded at the beginning and end of the assembly, and through paper pre/post surveys (closed- and open-ended questions) of all students in the workshops. To assess change, we used McNemar's chi-square test and a mixed model (adjusted for demographics) accounting for clustering at the school level. We employed counts, means, and proportions of state-reported school data and web analytics to assess reach of the school-based dissemination and web-based media.

RESULTS: PSA themes included the association of DM2 with the built environment, industry advertising, and racial and socioeconomic disparities. In 13 high schools over 6 months, 1900 students participated in the poet-led assemblies and 263 in the workshops. The participating schools enrolled on average 982 students, 66 % of whom qualified for free or reduced lunches. Seven hundred eighty-one students responded to assembly surveys. Fifty-six percent were female with an average age of 15.7 years, and 28 % were Latino, 27 % Asian, 18 % African American, and 14 % multi-ethnic. Ninety-two percent agreed that DM2 is preventable after the assembly compared to 70 % before (McNemar's $p<0.001$, adjusted mixed model OR 5.3), and 83 % after identified environmental factors in addition to individual behaviors as influencing DM2 risk compared to 34 % before ($p<0.001$, OR 13.1). Using a Likert scale, 59 % after responded "I care a lot" about preventing DM2 compared to 29 % before ($p<0.001$, OR 9.1). In the workshops, students identified the DM2 epidemic as a social justice issue. To date, the 11 web-based video PSAs combined had 72,232 views. The campaign's Facebook page has 383 "likes" and the Twitter account has 342 followers.

CONCLUSIONS: A youth-targeted, youth-generated social marketing campaign improves short-term knowledge and attitudes about DM2 risk. Through high schools, we reached our target population, and web-based media has potential for extending this reach. This type of campaign may be one avenue toward engaging diverse, high-risk youth to change the conditions that increase DM2 risk.

EREFERRALS AND ECONSULTS: DOWNSTREAM IMPACT ON ACCESS, UTILIZATION, AND COST IN A FEE-FOR-SERVICE SETTING Nathaniel Gleason¹; Jennifer J. Monacelli⁶; Chanda Ho²; Sara Ackerman³; Priya A. Prasad⁴; Michael Wang⁵; Don Collado¹; Delthia McKinney⁵; Ralph Gonzales¹. ¹UC San Francisco, San Francisco, CA; ²UC San Francisco, San Francisco, CA; ³UC San Francisco, San Francisco, CA; ⁴UC San Francisco, San Francisco, CA; ⁵UCSF Medical Center, San Francisco, CA; ⁶Michigan State University, Grand Rapids, MI. (*Tracking ID #1939845*)

BACKGROUND: Demand for specialty care services exceeds supply at many academic referral centers. Delays in access to specialty care are common, and are anathema to patient-centered care. Electronic referrals (eReferrals) and non-face-to-face consultations (eConsults) are mechanisms associated with significant improvements in the specialty care referral process in integrated delivery systems with aligned incentives. Translating these innovations to academic medical centers (AMCs) has been challenging; reimbursement remains largely fee-for-service, and Medicare and most commercial payers do not pay for eConsults. With support from the Medicaid waiver program (DSRIP), UCSF Medical Center implemented a new referral platform. The system is designed to improve information exchange at the point-of-referral and to provide an eConsult option, allowing PCPs to request timely input from specialists for data-oriented referral problems that the PCP does not perceive to require in-person evaluation of the patient by the specialist. In this study, we analyzed the downstream impact of this program on PCP referral rate, specialty care access, and costs.

METHODS: eReferral/eConsult Platform: In May 2012, UCSF introduced a structured referral platform within the electronic health record (EHR) (Epic Systems) with over 90 problem-specific, structured templates providing clinical decision support at the point-of-referral. An eConsult option was added in September 2012. The expected eConsult response time is 3 business days. Upon review, if the specialist determines the case is not appropriate for eConsult, the specialist converts the eConsult to a standard new-patient visit. Specialists receive a payment corresponding to 0.5 wRVU per completed eConsult. PCPs receive 0.5 wRVU credit toward productivity targets. In recognition of the fact that the PCP maintains management responsibility for the referral problem. Study populations: The program included 8 primary care sites and 12 medicine subspecialty practices. The study population includes all eligible PCPs ($n=178$) and all referrals to participating practices for patients assigned to an eligible PCP during baseline (9/1/11–8/31/12) and study periods (9/1/12–4/30/13) ($n=13,738$ referrals representing 11,597 unique patients). (To account for seasonal effects on ED visits and hospitalizations, we used baseline and intervention periods of Oct–April 2012 vs Oct–April 2013 for the utilization and cost analysis). We obtained data on referral rates from the EHR scheduling database. Data on utilization and costs were obtained from the University Health System Consortium. Analysis: We calculated the total referral rate per 100 primary care visits per month, and the proportion of these sent as eConsults. To compare the trends in referral rate, we modeled the effect of time using a linear spline analysis with two knots to determine whether there were differences in the trajectory following the introduction of the structured referral system and eConsults. To measure impact on access to specialty care, the proportion of UCSF primary care patients who received specialty care input (office visit or eConsult) within 14 business days in the baseline and eConsult periods were compared using chi-square tests. Mean monthly ambulatory, emergency department, hospital utilization and professional fee costs occurring within 120 days following each referral or eConsult were log transformed to minimize effects of outlier data. Average costs were compared between baseline ($n=6$ months) and eConsult ($n=6$ months) periods with unpaired t-tests.

RESULTS: Of eligible PCPs, 69 % placed at least one eConsult. Based on the spline analysis, the referral rate declined from 12.42 per 100 primary care visits during the baseline period to 10.66 per 100 primary care visits in August 2012 (11 % decrease; $p=0.011$). eConsults were added as an option in September 2012, and the referral rate remained stable though the remainder of the study. eConsults were used for 8.2 % of total referrals. The proportion of patients who received specialty care input (office visit or eConsult) within 14 business days improved from 39 to 49 % ($p=0.001$) across all participating specialties. Specialties with greatest improvements were pulmonary (from 20 to 50 % ($p=0.004$)), GI (from 19 to 40 % ($p=0.001$)) and nephrology (from 50 to 74 % ($p=-.05$)). The proportion of referrals with an ED visit during the 120-day period following referral or eConsult decreased from 9.8 to 8.6 %, and there was a significant reduction in total ED pro-fee costs ($pss 0.016$). Mean ambulatory and hospital pro-fees did not change between periods.

CONCLUSIONS: This combined eReferral (enhanced referral platform) and eConsult program showed robust adoption and had significant impact on referral rate and specialty care access time. The significant impact on ED costs may represent a downstream benefit of improved access to care.

ESTABLISHING GUIDELINES FOR REFERRAL TO ORTHOPAEDIC SPECIALTY CARE: CONSENSUS USING THE MODIFIED DELPHI METHOD
Maria E. Otto; Carlin Senter; Christy K. Boscardin; Ralph Gonzales; Nathaniel Gleason. University of California San Francisco, San Francisco, CA. (Tracking ID #1939439)

BACKGROUND: Standardized electronic referrals can improve physician communication, provider experience, and wait times. The Council for Subspecialty Societies, sponsored by the American College of Physicians, defines the features of high-quality care coordination between primary care and specialty care in a Patient Centered Medical Home-Neighborhood (PCMH-N). Specifically, high-quality referrals in the PCMH-N are defined as referrals that facilitate effective transfer of clinical information, elicit a clinical question, convey expectations about management roles, and ensure appropriate and timely consultation. The University of California San Francisco (UCSF) implemented an eReferral system, integrated into the Electronic Health Record, in which structured templates facilitate referrals to specialty care that are in keeping with PCMH-N recommendations and provide decision support at the point-of-care. Expanding this program to orthopaedics, we found limited available guidelines for orthopaedic problems regarding referral timing, management steps to be taken prior to referral, imaging in advance of referral, and clinical questions for which a non-face-to-face visit (eConsult) with an orthopaedist might be appropriate. This study describes our experience using the modified Delphi method to inform development of standardized orthopaedic referral guidelines by identifying consensus between referring PCPs and orthopaedic clinicians on specific recommendations.

METHODS: To represent a broad range of expertise, all UCSF Physicians, Physician Assistants, and Nurse Practitioners who provide care to adult patients in the UCSF orthopaedic clinic were asked to participate (Foot & Ankle =2, Hand=3, Sports=5, Arthroplasty=6, Spine=8). Primary care providers (PCPs) volunteered in response to a recruitment email sent to all 8 UCSF adult primary care practices ($n=22$ volunteers). The expert panel completed two rounds of anonymous electronic surveys over a period of 4 weeks. PCPs answered all questions, while clinicians in the orthopaedic practice answered only questions related to the joints each treated in practice. Surveys were composed of clinical scenarios followed by questions about appropriate pre-referral evaluation, conservative management, and the utility of non-face-to-face consultation (eConsult) with an orthopaedist. Scenarios were written for the most commonly referred orthopaedic diagnoses and constructed to differ by one variable at a time (e.g. chronic vs. acute, a sedentary vs. athletic patient). The degree of importance for each possible intervention was ranked on a 5-point Likert scale (strongly disagree to strongly agree). The second round survey included the median response for each group (PCPs and orthopaedic clinicians) from the first round for each question, allowing panelists to factor in these initial responses when re-visiting the scenarios in round two. Consensus was defined as $\geq 70\%$ of PCPs and orthopaedic clinicians giving a score of 1–2 or 4–5.

RESULTS: All 22 PCPs completed the Round 1 & 2 surveys. Nineteen orthopaedic clinicians completed Round 1 and 17 completed Round 2 (Response Rate: 79 % & 70 % respectively). Consensus was reached in 142 of 214 items. Most notably, PCPs and orthopaedists agreed that 1) X-ray should be performed in advance of referral for most clinical scenarios while pre-referral MRI is recommended in select scenarios: acute knee pain concerning for ligamentous injury and/or meniscal tear, spinal stenosis, chronic neck pain with arm pain in a dermatomal distribution, and intractable neck pain. 2) Pre-referral physical therapy is recommended for the following conditions: Achilles tendinitis, groin pain concerning for labral tear or impingement in a patient ≥ 65 years old, trochanteric bursitis, osteoarthritis of the hand, shoulder, and knee, meniscal tear in a patient ≥ 65 years old patellofemoral knee pain, shoulder impingement syndrome, frozen shoulder, medial and lateral epicondylitis, and spinal stenosis. 3) PCP management guided by electronic consultation by an orthopaedist, in place of a patient visit, could be appropriate for the following conditions: chronic pain after ankle sprain, plantar fasciitis, stress fracture of the foot, osteoarthritis of the hand, shoulder, knee, and hip, trochanteric bursitis, degenerative meniscal tear, patellofemoral pain, shoulder impingement syndrome, medial epicondylitis, intractable low back and neck pain.

CONCLUSIONS: This consensus is the first step in improving the quality of orthopaedic referrals. Through this effort, we hope to have established meaningful referral guidelines that represent the collective opinions of experts with the premise that ‘pooled intelligence’ enhances individual judgment. Our future efforts will aim to measure whether or not standardized referral templates developed using the Delphi method in consultation with a panel of experts and following the current PCMH-N guidelines improve referral efficiency and quality.

ESTIMATING TOBACCO-, ALCOHOL-, AND DRUG-ATTRIBUTABLE DEATHS AND THEIR CONTRIBUTION TO MORTALITY DISPARITIES AMONG HOMELESS ADULTS
Travis P. Baggett^{1,2}; Yuchiao Chang¹; Bianca Porneala¹; Jessie M. Gaeta^{2,3}; James J. O'Connell^{2,1}; Nancy A. Rigotti¹. ¹Massachusetts General Hospital, Harvard Medical School, Boston, MA; ²Boston Health Care for the Homeless Program, Boston, MA; ³Boston University School of Medicine, Boston, MA. (Tracking ID #1939356)

BACKGROUND: Homeless individuals have a high prevalence of substance use disorders and experience excess mortality rates in comparison to non-homeless people. Our objective was to estimate the burden of deaths attributable to tobacco, alcohol, and drug use in a large cohort of homeless adults, and to assess the contribution of substance-attributable mortality to the disparity in all-cause mortality with the general population.

METHODS: We assembled a cohort of 28,033 adults aged ≥ 18 years who were seen at Boston Health Care for the Homeless Program in 2003–08. We used probabilistic methods to cross-link this cohort with Massachusetts mortality files spanning the same years. For decedents, we based causes of death on ICD-10 underlying cause codes in the death occurrence files. We used accepted epidemiologic methods to estimate population attributable fractions (PAFs) for causes of death that high-quality studies have demonstrated to be causally related to the use of tobacco, alcohol, or drugs. For each cause of death, the PAF represents the proportion of these deaths that would not have occurred in the absence of tobacco, alcohol, or drug use. We used Monte Carlo simulation methods to generate 95 % confidence intervals for our PAF estimates. For each condition, we multiplied the PAF by the count of deaths to estimate the number of deaths attributable to tobacco, alcohol, or drug use. For conditions related to more than one substance, we used standard methods to account for overlapping attribution. We divided the number of attributable deaths by the person-time at risk to generate attributable rates. As a basis for comparison, we used the same methods to estimate substance-attributable mortality rates for the 2003–08 Massachusetts general population.

RESULTS: Of 1302 deaths, 236 (95 % CI 215–254) were tobacco-attributable, 215 (95 % CI 199–232) were alcohol-attributable, and 286 (95 % CI 285–287) were drug-attributable. After accounting for overlap, about 52 % ($N=676$, [95 % CI 655–698]) of all deaths were attributable to any of these substances. Drug use was the predominant contributor to substance-attributable deaths under the age of 50 years (63 %), while tobacco use was the major contributor to substance-attributable deaths over the age of 50 years (55 %). In comparison to the Massachusetts general population, age- and sex-stratified mortality rates in the homeless cohort were 3–4 times higher for tobacco-attributable causes, 6–12 times higher for alcohol-attributable causes, 8–17 times higher for drug-attributable causes, and 5–11 times higher for all substance-attributable causes combined. Disparities in substance-attributable deaths accounted for nearly 60 % of the age- and sex-standardized mortality rate difference between the homeless cohort and the Massachusetts general population.

CONCLUSIONS: Over half of all deaths among homeless people are attributable to tobacco, alcohol, or drug use. Substance-attributable deaths are a major contributor to mortality disparities between homeless adults and the general population, but they do not fully explain the mortality gap between these groups of people. Efforts to reduce mortality among homeless individuals should focus on the expansion of substance abuse treatment services in conjunction with comprehensive health care and social policy interventions to address non-addiction sources of excess mortality in this vulnerable population.

EVALUATING INPATIENT HOSPITAL CHARGE VARIABILITY USING LOCAL HEALTH AND MARKET FACTORS
James D. Park¹; Edward Kim²; Rachel M. Werner³. ¹Rutgers, Robert Wood Johnson Medical School, New Brunswick, NJ; ²The College of New Jersey, Ewing, NJ; ³Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA. (Tracking ID #1937089)

BACKGROUND: In May 2013, the Center for Medicare and Medicaid Services released previously undisclosed information about the price of hospital care. Within a diagnosis related group, inpatient hospital charges to Medicare demonstrated a wide range of charges across US hospitals. This variation in hospital charges remains unexplained, and this study examines its relationship to the local market environment in which hospitals operate.

METHODS: This descriptive study evaluated the CMS Inpatient Provider Charge data of over 3000 US hospitals using clustered, multivariate linear regression. This analytic approach examined how county health, socioeconomic, and market factors relate to hospital charges. Six common inpatient conditions—cellulitis, chronic

obstructive pulmonary disease, congestive heart failure, myocardial infarction, orthopedic surgeries, and pneumonia—were chosen for the analysis. Related DRGs for each condition were grouped together, and a weighted average charge for each hospital was calculated based on the proportion of discharges per DRG. Based on a conceptual model, a common set of covariates was used to create a single regression model for each condition. The analysis used various county-level measures of *health status* (years of potential life lost per 100,000 population, percent of adults who report fair or poor health, percent days reported as mentally unhealthy per month, diabetes prevalence, obesity prevalence); *health behavior* (prevalence of smoking, no leisure time activity, or heavy alcohol drinking); *clinical access and quality* (prevalence of uninsured status, preventable hospital stays rate, percent of diabetics who received a hemoglobin A1c test, number of primary care physician per 100,000 population); *socioeconomics status* (percent of a 9th grade cohort that graduates in 4 years, prevalence of unemployment, of children living in poverty, and of children living in single-parent homes, median household income, violent crime rate per 100,000 population); the *built environment* (number of accessible recreational facilities per 100,000 population); *demographics* (percent of the population that is African American, Asian, Latino, or other race, and percent of the population over the age of 65); and the *hospital market* (for-profit status, proportion of hospital discharges within the county) from every US county and hospital. All analyses controlled for other market factors such as the hospital wage index, disproportionate share hospital index, hospital cost-to-charge ratio, and the county-level Herfindahl-Hirschman Index. Covariates were extracted from multiple datasets including the US Census Bureau, Behavioral Risk Factor Surveillance System, National Center for Chronic Disease Prevention and Health Promotion, CMS Impact, CMS Provider of Service, County Business Patterns, American Community Survey, Dartmouth Atlas of Health Care, Bureau of Labor Statistics, Small Area Income and Poverty Estimates, Federal Bureau of Investigation Uniform Crime Reporting, National Center for Health Statistics, and the National Center for Educational Statistics. All regression analyses were clustered by county, and statistical testing was deemed significant with *p*-values <0.05.

RESULTS: The mean number of hospitals included across six regressions was 2603. Across all six conditions, hospital charges were associated with uninsured status and resulted in \$210.28–\$623.26 higher charges for every 1% increase in the prevalence of uninsured status (*p*<0.01). In addition, hospital charges were associated with for-profit hospital status across all six conditions and resulted in \$1230.47–\$7772.10 higher charges than not-for-profit status (*p*<0.05). In all conditions except myocardial infarction, hospital charges were associated with unemployment status and resulted in \$295.83–\$752.53 higher charges for every 1% increase in unemployment prevalence (*p*<0.05). Health behavioral factors such as smoking, physical inactivity, and excessive alcohol consumption, or health status factors such as premature death, fair or poor health status, poor mental health days, or diabetes were largely unassociated with hospital charges. Of all health factors utilized in this study, only obesity was repeatedly associated with hospital charges in four of the six conditions, resulting in \$232.57–\$513.92 higher charges for every 1% increase in obesity prevalence (*p*<0.05).

CONCLUSIONS: Non-health related factors, such as uninsured, unemployment, and for-profit hospital status, were consistently associated with higher hospital charges. In contrast, nearly all health factors had no association to inpatient hospital charges. This research raises concerns about a regressive pricing strategy that is indifferent to health status but charges vulnerable and uninsured populations higher prices.

EVALUATING THE UTILITY OF OSTEOPOROSIS SCREENING TOOLS (OST, FRAX) AND VIDEO EDUCATION IN HOSPITALIZED PATIENTS

Eve Thau; Eileen Hennrikus. Penn State Milton Hershey Medical Center, Hershey, PA. (Tracking ID #1938794)

BACKGROUND: Approximately eight million women and two million men in US suffer from osteoporosis, with the cost of fragility fractures an estimated \$10–15 billion annually. To calculate osteoporotic fracture risk, the FRAX (Fracture Risk Assessment Tool), takes into account age, weight, height, gender, parental fractures, tobacco and alcohol use and secondary causes for osteoporosis. A simpler risk assessment measurement is the OST (Osteoporosis Self-

Assessment Tool), a calculation using only age and weight. We proposed that osteoporosis risk assessment and education can be accomplished in patients hospitalized on the inpatient internal medicine service. Our objectives include (1) assess if OST compared to FRAX is a useful tool to screen inpatients for osteoporosis, (2) determine if osteoporosis video education is well received and (3) determine if patients hospitalized for other illnesses will act upon knowledge and education for a preventive health measure.

METHODS: Three days per week for 2 months, an OST was calculated on all internal medicine inpatients >60 years old. One hundred twelve patients with an OST > 2, deemed not at risk for osteoporotic fracture then had a FRAX calculated by chart review. The 72 patients with an OST < 2, deemed at risk for osteoporotic fracture, were consented for further study. Patients were excluded if they were not interested in participating, had altered mental status or were too sick to participate. Fifteen eligible patients were excluded. Patients were given the FRAX questionnaire, a 7-question osteoporosis pre-test, followed by an NIH-sponsored educational osteoporosis video, and the same test post-video. Afterwards, patients were asked their opinion of the video education, and if they would take any new measures following hospital discharge to help improve bone strength and prevent osteoporosis.

RESULTS: 184 patients were evaluated, mean age 73 years old, and mean weight 91 kg. Causes for admission were primarily cardiovascular, pulmonary, and renal disease with only two patients admitted with bone fractures. Forty percent of internal medicine inpatients were found to be at osteoporotic fracture risk by the OST calculation. Of those 72 patients, 68 (94 % *p*=0.001) were also found to be at risk for both major fracture and hip fracture by FRAX calculation. Of the 112 patients not found to be at risk by OST, 92 (84 %, *p*=0.01) correlated with FRAX risk. Of the 20 patients where the FRAX found risk and the OST did not, 10 (50 %) had an obvious secondary cause for osteoporosis such as a history of chronic renal failure or prednisone usage. Of the other 10 patients who did not have a secondary cause for osteoporosis, eight of them were women over the age of 68, median age 74 years old. 30 % (22) of the at risk patients had been previously counseled by their physician for osteoporosis, and 40 % (29) of these patients were already taking calcium supplements, vitamin D and 12 % (9) were taking bisphosphonates before hospital admission. 36 % (26) patients previously had a DEXA screen before participation in the study. With regards to patient education, we found an improvement of 20.6 % when comparing quiz scores conducted before and after exposure to the NIH-sponsored educational video *p*=0.001. Patients found this video very helpful in learning more about osteoporosis and preferred it to written material. After being informed of their risk, and after watching the video, 28 % (20) patients said that they would address osteoporosis, 16 would make mild lifestyle changes and only four planned to speak with their doctor and pursue treatment. Patients who opted to not alter lifestyle or seek further medical advice regarding osteoporosis noted that they were too sick or too old.

CONCLUSIONS: The OST is an effective risk assessment tool for osteoporosis. OST does not capture those patients with obvious secondary causes for osteoporosis. Of those patients at risk, 60 % had not had osteoporosis addressed by their primary care physician. Video education was well received in the hospital and revealed a significant improvement in knowledge about osteoporosis. However, after being informed of their fracture risk and receiving education only 28 % of patients would pursue treatment. A significant number of patients were found to be at risk and untreated for osteoporosis. Although the education was well received, preventive measures for osteoporosis were not a priority compared to the acute issues for which patients are hospitalized. Optimally, screening should be done in the outpatient setting, but perhaps inpatient screening and education can be useful if translated to the primary care physician to address when acute issues recede.

EVALUATION OF AN ELECTRONIC HEALTH RECORD PROMPT FOR HEPATITIS C ANTIBODY SCREENING OF BABY BOOMERS IN PRIMARY CARE - A CLUSTER RANDOMIZED CONTROL TRIAL

Katherine Krauskopf¹; Natalie Kil¹; Anastasia Sofianou²; Wilma Toribio¹; Joanne Lyons³; Mark Singer³; Joseph Kamny¹; Bryce Smith⁵; David B. Rein⁴; Alex Federman¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³Mount Sinai Health System, Huntington, NY; ⁴NORC at University of Chicago, Atlanta, GA; ⁵Centers for Disease Control and Prevention, Atlanta, GA. (Tracking ID #1938222)

BACKGROUND: The CDC recommends one-time hepatitis C virus (HCV) testing for all persons born between 1945 and 1965 (birth cohort testing). Electronic Health Records (EHR) may represent an effective tool to increase testing uptake. We sought to assess use and acceptance of an EHR alert to promote birth cohort testing in primary care, and determine subsequent prevalence of positive HCV tests among previously undiagnosed individuals.

METHODS: We conducted a cluster randomized controlled trial of three adult primary care practices (teaching and faculty) within the Mount Sinai Medical System, NY, beginning 4/2013 and ongoing to 3/2014. Ten clusters were identified based on provider type, geography, and patient population, and randomized to intervention (EHR screening prompt) or control (usual care). A member of the research team gave a brief intro to all physicians (MD), nurse practitioners (NP), medical assistants (MA), and registered nurses (RN), regardless of study arm assignment, about HCV, birth cohort testing recommendations, and the study. In intervention clusters, the EHR (Epic Systems, Madison, WI) triggered a screening prompt when eligible patients (those without prior HCV antibody [Ab] testing or HCV diagnosis born during 1945–1965) registered for a visit. When the MA/RN opened the electronic chart before the MD/NP, the EHR generated a prompt to pertain an HCV Ab order for the MD/NP to discuss with the patient, then sign or delete. When the MD/NP opened the chart first, the EHR generated an alert to suggest HCV testing, and provided an HCV Ab order for acceptance or deletion. At study completion, differences in characteristics of intervention and control providers, and among the patients seen in intervention vs. control clusters, will be measured using t test and X² test. We will compare testing and HCV positivity prevalence between intervention and control arms, as well as process outcomes, using generalized estimating equations.

RESULTS: After 6 months of data collection, 146 of 154 MD/NP (95 %) approached have consented to participate, as have 73 of 78 (93 %) RN/MA. There have been 10,857 eligible intervention-arm visits and 7,372 control-arm visits. Of these, 2,176 HCV Ab tests were ordered in the intervention arm (20 %) versus 225 ordered in the control arm (3 %). There were 20 positive tests in the intervention arm (0.9 % of those tested) versus five in the control arm (2.2 % of those tested).

CONCLUSIONS: Preliminary data show that the EHR intervention results in a higher rate of testing and consequently finds more cases than usual care. While targeted methods of usual care detect a higher prevalence, testing occurs too infrequently to match the aggregate case detection of the EHR prompt. Although successful in detecting more cases, only 20 % of eligible patients were tested via the intervention, suggesting that modification of the intervention may be needed to achieve HCV testing among all birth cohort adults.

EVALUATION OF STEPPED CARE FOR CHRONIC PAIN (ESCAPE) IN VETERANS OF IRAQ AND AFGHANISTAN: A RANDOMIZED TRIAL

Matthew J. Bain^{1,2}; Dennis Ang⁴; Jingwei Wu²; Samantha D. Outealt¹; Christy Sargent¹; Amanda Gerwig¹; Arlene Schmid⁶; Teresa Damush^{1,3}; Zhangsheng Yu⁵; Louanne W. Davis⁷; Kurt Kroenke^{1,3}. ¹VA HSR&D Center for Health Information and Communication, Indianapolis, IN; ²Indiana University School of Medicine, Indianapolis, IN; ³Regenstrief Institute, Inc, Indianapolis, IN; ⁴Wake Forest School of Medicine, Winston-Salem, NC; ⁵Indiana University School of Medicine, Indianapolis, IN; ⁶Colorado State University, Fort Collins, CO; ⁷Roudebush VA Medical Center, Indianapolis, IN. (Tracking ID #1937595)

BACKGROUND: Despite the prevalence and substantial functional, psychological, and economic impact of chronic musculoskeletal pain on military personnel and veterans, there have been few intervention studies to treat chronic pain in these populations. We conducted a randomized controlled trial to determine if a stepped-care intervention is more effective than usual care in reducing pain-related disability, pain interference, and pain severity.

METHODS: We recruited patients from post-deployment and five general medicine clinics at a Veteran Affairs Medical Center. Participants included 242 Operation Enduring Freedom and Operation Iraqi Freedom Veterans with chronic, disabling musculoskeletal pain of the cervical or lumbar spine or extremities (shoulders, knees, and hips). The intervention involved 12 weeks of analgesic treatment and optimization according to an algorithm coupled with pain self-management strategies (Step 1) followed by 12 weeks of brief cognitive behavioral therapy (Step 2). All aspects of the intervention were delivered by nurse care managers. The primary

outcome was pain-related disability (Roland Morris Disability Scale) at 9 months. We also assessed pain interference (Brief Pain Inventory) and pain severity (Graded Chronic Pain Scale). The primary analysis compared the change from baseline to 9 months between study groups. To estimate treatment effects, we used random-effect linear regression adjusted for age, sex, severity of pain, and baseline value of outcome measure. Analyses were conducted with SAS version 9.13.

RESULTS: There were no significant baseline differences between stepped-care intervention and usual care arm. The mean age of ESCAPE participants was 36.7 years (range=21 to 73 years) and 88.4 % were men. In terms of racial mix, 77.7 % were white, 13.0 % were black, and 9.2 % classified as other. The primary site of pain was the low back (57 %) followed by knee pain (21.6 %), neck pain (7.5 %), shoulder pain (7.1 %), and hip pain (6.6 %). Two-thirds (66.4 %) had been in the Army, 74.9 % had been deployed to Iraq, 8.8 % deployed to Afghanistan, and 16.3 % deployed to both conflicts. One hundred twenty-one intervention participants and 120 usual care participants were included in the primary analysis. At 9 months, the mean decrease from baseline in the Roland Morris Disability Scale score was 1.6 points (95 % confidence interval [CI] 0.72–2.6) in the usual care group and 3.4 points (95 % CI 2.5–4.3) in the stepped-care intervention group (between group difference of -1.8 points, -3.1 to -0.51; $p=0.0063$). The mean decrease from baseline in the Brief Pain Inventory interference score was 0.86 points in the usual care group and 1.6 points in the intervention group (between group difference of -0.69 points, -1.3 to -0.12; $p=0.0170$). The Graded Chronic Pain Scale severity score was reduced by 7.1 % (95 CI's 2.7 % to 11.5 %) and 20.4 % (95 % CIs 14.3 % to 26.6 %), respectively (between group difference 13.3 %, 11.6 % to 15.1 %; $p=0.0013$).

CONCLUSIONS: A stepped-care intervention that combined analgesics, self-management strategies, and brief cognitive behavioral therapy resulted in a significant reduction in pain-related disability, pain interference, and pain severity in Veterans of Iraq and Afghanistan with chronic, disabling musculoskeletal pain of the spine and extremities.

EVALUATION OF THE MODIFIED HEART SCORE IN PREDICTING OUTCOMES IN PATIENTS WITH LOW-RISK CHEST PAIN

Carlos Calle-Muller; David Paje; Matthew Cerasale; Iani Patsias. Henry Ford Hospital, Detroit, MI. (Tracking ID #1940326)

BACKGROUND: The HEART (History, ECG, Age, Risk factors and Troponin) score was recently shown to be potentially useful in identifying patients presenting with chest pain with a very low pretest probability of acute coronary syndrome (ACS) and where further testing may not be beneficial. However, all of the previous studies relied on the investigators' retrospective appraisal of the patient's chest pain history and used a nonstandard definition for classifying chest pain. We adopted the American Heart Association's clinical classification of chest pain to modify the HEART score and prospectively evaluated its ability to predict outcomes in patients with low-risk chest pain.

METHODS: Patients presenting with chest pain were considered at low risk for ACS and were referred to the observation unit of an 805-bed hospital if they had none of the following features: ongoing chest pain, dynamic ST-segment changes and cardiac troponin $I \geq 0.20$ ng/mL. As part of the initial evaluation, clinicians filled out a standard data collection tool that included clinical variables necessary to calculate the modified HEART Score (Table 1). The occurrence of the composite endpoint of death from any cause, acute myocardial infarction and coronary revascularization within 30 days of the visit were recorded through follow-up phone call and medical records review. Sensitivity, specificity, and positive and negative predictive values were calculated.

RESULTS: Of the 420 patients that were enrolled, 298 (71 %) had complete follow-up data and were included in the analysis. The composite endpoint occurred in 9 (3 %) patients within 30 days (1 died, 3 had nonfatal acute myocardial infarction and 5 had significant disease requiring coronary revascularization). A cardiac endpoint occurred in 3 of 155 (1.9 %) patients with a HEART score 0 to 3, and in 6 of 143 (4.2 %) with a score of >3 ($p=0.25$). The sensitivity, specificity, and positive and negative predictive values of a HEART score >3 in predicting a cardiac endpoint are shown in Table 2.

CONCLUSIONS: The incidence of significant coronary events is very low among patients presenting with chest pain who do not have ongoing chest pain, dynamic ST-

segment changes or abnormal cardiac troponin. The modified HEART score does not appear to be useful in further identifying those who are at very low risk.

Table 1. Modified HEART Score

Clinical Features		Points
<u>History</u>	1) substernal chest discomfort with a characteristic quality and duration that is 2) provoked by exertion or emotional stress and 3) relieved by rest or nitroglycerine	2
	meets 2 of the above characteristics	1
	meets 1 or none of the above characteristics	0
<u>ECG</u>	significant ST depression	2
	nonspecific repolarization abnormality	1
	normal	0

Prevalence (%):	3.02	95%CI: 1.39 to 5.66

EVALUATION OF THE MODIFIED NORTH AMERICAN CHEST PAIN RULE TO IDENTIFY PATIENTS AT VERY LOW RISK OF ACUTE CORONARY SYNDROME Matthew Cerasale; David Paje; Carlos Calle-Muller; Iani Patsias. Henry Ford Hospital, Detroit, MI. (*Tracking ID #1940296*)

BACKGROUND: The North American Chest Pain Rule (NACPR) was developed to identify patients presenting with chest pain who are at very low risk for a cardiac event and who may be suitable for discharge from the emergency department without additional investigations. However, this tool defines chest pain as typical for acute coronary syndrome based on the judgment of the attending emergency physician, which makes it difficult to standardize. We adopted the American Heart Association's definition of typical angina to modify the chest pain component of the NACPR and we prospectively evaluated its ability to predict outcomes among patients with low-risk chest pain.

METHODS: Patients were considered to have low-risk chest pain and were referred to the observation unit of an 805-bed hospital if they had no ongoing

chest pain, no dynamic ST-segment changes and no abnormal cardiac troponin value. During their initial evaluation, clinicians filled out a standard data collection tool that included clinical variables necessary to capture the components of the modified NACPR (Table 1). Primary outcome was the composite of all-cause mortality, acute myocardial infarction and coronary revascularization within 30 days of the visit. Follow-up was done through phone call and medical records review. Test characteristics of the modified rule were calculated.

RESULTS: Baseline data was recorded on 419 patients, one patient was excluded because of ST-segment elevation in the initial ECG. A total of 298 patients had complete follow-up data (72 % with phone follow-up) and were included in this analysis. The composite endpoint occurred in 9 (3 %) patients within 30 days (1 died, 3 had nonfatal acute myocardial infarction and 5 had significant disease requiring coronary revascularization). All 9 events occurred in patients that had at least one component of the modified NACPR. The

sensitivity, specificity, and positive and negative predictive values of the presence of any component of the modified NACPR in predicting the primary outcome are presented in Table 2.

CONCLUSIONS: The modified NACPR appears useful in identifying chest pain patients who are at very low risk of acute coronary syndrome and who may benefit from early discharge from the emergency department.

Table 1. Modified North American Chest Pain Rule

A patient with chest pain and possible acute coronary syndrome can be safely discharged without additional diagnostic testing if <u>NONE</u> of the following five criteria is present:	
1. New ischemia on initial ECG	
2. History of coronary artery disease	
3. Pain is typical for angina, which has <u>ALL</u> of the following features: a) substernal chest discomfort with a characteristic quality and duration that is b) provoked by exertion or emotional stress and c) relieved by rest or nitroglycerine	
4. Initial or 6-hour troponin cardiac troponin is greater than 99th percentile	
5. Age greater than 50 years	

Table 2. Test Characteristics of the Modified NACPR in Patients with Low-Risk Chest Pain

NACPR Criteria Present	Composite Outcome of Death, Acute Myocardial Infarction and Coronary Revascularization	
	Yes (n)	No (n)
Yes	9	220
No	0	69
Sensitivity (%):	100	95%CI: 66.21 to 100
Specificity (%):	23.88	95%CI: 19.08 to 29.22
Positive likelihood ratio:	1.31	95%CI: 1.23 to 1.40
Negative likelihood ratio:	0	n/a
PPV (%):	3.93	95%CI: 1.82 to 7.33
NPV (%):	100	95%CI: 94.74 to 100
Prevalence (%):	3.02	95%CI: 1.39 to 5.66

EXAMINING PERCEIVED BARRIERS TO GOOD NUTRITION IN A SUBSET OF HOMELESS WOMEN IN URBAN BIRMINGHAM, ALABAMA

Sandhya L. Kumar¹; Jeremy B. Walker¹; Dennis J. Pillion²; Amanda Willig²; April Agne²; Andrea Cherrington². ¹University of Alabama at Birmingham, Birmingham, AL; ²University of Alabama at Birmingham, Birmingham, AL. (Tracking ID #1939137)

BACKGROUND: The relationship between homelessness and poor health is well-recognized. Many of today's food-insecure homeless suffer from obesity-related complications, including hypertension and diabetes. Homeless individuals who regularly access meals provided by charitable services are at the mercy of well-meaning food-providers. The lack of control over quality and quantity of meals is often viewed as an insurmountable barrier, and can be particularly frustrating for patients and their health educators/providers as they attempt to discuss dietary modifications as an avenue for chronic disease management. The resulting apathy further perpetuates disregard for nutrition. In this study, we used a mixed-methods approach to further explore the various factors that influence dietary choice in the homeless population. In partnership with three community organizations, we interviewed and surveyed women who sought services from an urban Birmingham charitable meal program with the aim of exposing the perceptions and attitudes they held regarding good nutrition, as well as to assess if any relationships existed between factors such as health status, extent and accuracy of nutrition knowledge, food security, and determinants of healthy food choices.

METHODS: A convenience sample of 49 women was recruited over a 6 week period (Summer 2013) based on participation in meal services provided by a partner agency's charitable organization. In this mixed-methods study, 11 women in a transitional housing program took part in a semi-structured interview focused on perceived barriers to good nutrition and an 83-item questionnaire on demographics, health status, extent and accuracy of nutrition knowledge, food security, and

determinants of healthy food choices. Another 38 women recruited from the same institution's "Day Center" participated in the survey alone. Quantitative analysis was performed using SPSS. Qualitative content analysis was conducted to identify major categories and substantive themes.

RESULTS: Mean age category was 41–50 years. Diabetes and hypertension prevalence were 20 % and 53 %, respectively. Sixty-three percent of participants express a desire for a "special diet", 81 % citing for health concerns. Thematic analysis of interview scripts reveals food concepts (good versus bad foods, utility versus consequences), desired nutrition knowledge (food budgeting, how to shop, components of food), and influences on food choices (availability, access, competing demands, social reciprocity).

CONCLUSIONS: This subset of homeless experiences a high rate of hypertension and diabetes. Many in the homeless population display an interest in learning more about nutrition and having more control over dietary intake as a way of health management. However, for those on the streets or in temporary housing, meeting immediate physiological needs is the highest priority and dietary control is a secondary or tertiary concern. For these individuals, it seems most appropriate to impact diet by increasing the dietary adequacy and nutrition density of charitable meals. Nutrition-based education and lifestyle modification is a more practical and a desired avenue of chronic disease prevention and management in the transitional population. Individuals in transitional programs are focused on conquering higher order needs, such as security of employment, housing, and health. Given this consideration, this group seems the most amenable to productive discussion of dietary choices and nutrition education. Permanent incorporation of nutrition-based life-skills classes that focus on practical application of nutrition knowledge (i.e. food budgeting, how to shop, etc.) is a long-term investment that will help redefine concepts of food and benefit health status, financial status, and future generation's health-promoting behaviors.

EXAMINING THE POTENTIAL FOR CPOE SYSTEM DESIGN AND FUNCTIONALITY TO CONTRIBUTE TO MEDICATION ERRORS

*Arbor J. Quist¹; Alexandra Robertson¹; Thu-Trang Thach¹; Lynn A. Volk²; Adam Wright^{1,2}; Shobha Phansalkar^{1,3}; Sarah P. Slight^{1,4}; David W. Bates^{1,5}; Gordon D. Schiff^{1,5}.
¹Brigham and Women's Hospital, Boston, MA; ²Partners HealthCare, Wellesley, MA;
³Wolters Kluwer Health, Indianapolis, IN; ⁴University of Durham School of Medicine, Durham, United Kingdom; ⁵Harvard Medical School, Boston, MA.* (Tracking ID #1937921)

BACKGROUND: The Institute of Medicine has estimated that at least 1.5 million people are harmed by medication errors each year, thus efforts to reduce medication errors are an essential component to improving patient safety. While computerized prescriber order entry (CPOE) systems have reduced medication errors by creating legible and structured prescriptions and incorporating effective clinical decision support, they have also introduced new types of errors and must be optimally designed if medication errors are to be minimized. The FDA Brigham and Women's Hospital Computerized Prescriber Order Entry Medication Safety Project is an FDA-funded study conducted to better understand 10 CPOE systems, their functionality, features, interfaces, and safety, at 6 sites.

METHODS: We examined 10 different CPOE systems that varied in providers, vendors, and care settings across 6 different healthcare facilities. CPOE functionality data were collected through usability testing and detailed interviews with key CPOE system users and managers at each site. Test patients were created in each system and a CPOE Medication Safety Assessment Tool was developed to assist in eliciting and collecting structured information regarding the systems and their functions. These interviews and system evaluations were recorded, transcribed, and organized to highlight the similarities and differences between functionality in the systems.

RESULTS: We found a high level of inconsistency in the functionality of the CPOE systems evaluated, both within and across systems. Differences were found based on the system, care setting, care provider, and user role. Inpatient and outpatient systems at the same site were often unable to communicate, causing confusion and burdening clinicians. Users with different roles, such as physicians, nurses, and pharmacists, were found to have different system capabilities. Differences in workflow and medication prescribing across specialties led to some CPOE functionality that varied according to specialty. We found variation in discharge modules, override reasons, and hard stops. In searching institutional "paper trails" for CPOE system change reasons, we found a lack of system documentation of modifications and features. Some unanticipated findings included frequent user unawareness of obvious screen items and features as well as the surprising degree of local customization of various vendor-based systems (including customized interfaces, clinical decision support, order capabilities, and drug name presentation). We found studying CPOE system design features and rationale to be challenging as we attempted to connect the local patient safety logs. We observed differences in the mental models between CPOE system designers and users, complications with creating and using test patients to evaluate functionality, and difficulties in sharing and comparing useful, but proprietary, information. For example, it was often difficult or impossible to create test patients that were pregnant to simulate scenarios that would trigger pregnancy-related alerts.

CONCLUSIONS: A detailed and comprehensive understanding of the functionality of CPOE systems is important in building better systems that will reduce errors due to inefficiencies and inconsistencies in CPOE systems. Design features and tracking of issues arising from experience with these systems need to be more systematically catalogued. To more effectively prevent CPOE frustrations and errors, functionality needs to be improved through more standardized and less confusing interfaces and design features.

EXCESSIVE PERSPIRATION IS A PREDICTIVE FACTOR FOR AGGRAVATION OF RHABDOMYOLYSIS

*Masaki Tago¹; Naoko E. Furukawa^{3,1}; Yuka Naito¹; Akiko Eiri¹; Hiroki Aihara¹; Motoshi Fujiwara¹; Jun Tokutomi¹; Motosuke Tomonaga¹; Yuta Sakanishi²; Tsuneaki Yoshioka¹; Norio Fukumori²; Masaki Hyakutake¹; Itaru Kyoraku¹; Takashi Sugioka²; Shu-ichi Yamashita¹.
¹Saga Medical School Hospital, Saga, Japan; ²Saga Medical School, Saga, Japan; ³Saga Medical School, Saga, Japan.* (Tracking ID #1912342)

BACKGROUND: Rhabdomyolysis is a serious syndrome in which skeletal muscle fibers are damaged and release breakdown products such as creatinine kinase, or myoglobin into circulation. Some of the products are harmful and may lead to acute kidney injury, multiple organ failure, and even death. However, which factors are valuable in predicting the prognosis of this condition remains to be clarified. The

objective of the study was to elucidate the predictive factors for the prognosis of this syndrome.

METHODS: We analyzed consecutive 53 cases of rhabdomyolysis hospitalized at the department of general medicine of the Saga University Hospital in Japan by retrospective chart review from 2006 to 2013. The diagnosis of rhabdomyolysis was made by the presence of increased amount of serum creatinine kinase (CK) (>200 IU/L). At first, we divided the patients into two groups, one with serious consequences of death or acute kidney injury requiring blood purification therapies such as hemodialysis (HD) or continuous hemodialysis and filtration (CHDF) (Group A) and the others without ones (Group B). Then, we compared the characteristics of the patients of both groups about age, sex, number of days from onset to admission, main reason of admission, symptoms and signs (fever, muscle rigidity, extrapyramidal signs, the state of consciousness, excessive perspiration, dehydration), blood chemistry on admission (CK, blood urea nitrogen, creatinine, albumin, sodium and potassium), and maximum levels (CK, blood urea nitrogen, creatinine).

RESULTS: All of the 53 patients who were enrolled were Japanese (men, 60.4 %; women, 39.6 %; age 58.6 \pm 17.2). Group A consisted of 5 cases, in which 2 cases required blood purification therapies (HD/CHDF), and 4 cases deceased. According to univariate analysis, sex, age, fever, muscle rigidity, consciousness, CK, creatinine level on admission, and maximum level of CK were not significantly related to serious consequences. Only the finding of excessive perspiration on admission was related to the serious consequences (odds ratio 31.33, 95 % confidence interval 2.17–450.07, p -values <0.05).

CONCLUSIONS: The presence of excessive perspiration on admission is a useful factor to predict the serious prognosis of the patients who are admitted because of rhabdomyolysis.

EXPENSIVE DREAMS: SLEEP DURATION AND INCOME LEVELS IN GENEVA, SWITZERLAND

*Idris Guessous^{2,1}; Cédric Gubelmann¹; Jean-Marc Theler²; José Haba-Rubio³; Jean-Michel T. Gaspoz²; Pedro Marques-Vidal⁴.
¹Lausanne University Hospital, Lausanne, Switzerland; ²Geneva University Hospitals, Geneva 14, Switzerland; ³Center for Investigation and Research in Sleep, Lausanne University Hospital, Lausanne, Switzerland; ⁴Institute of Social and Preventive Medicine (IUMSP), Lausanne, Switzerland.* (Tracking ID #1935443)

BACKGROUND: Sleep has been shown to depend on socioeconomic status (SES), but the associations remain controversial. We aimed to assess associations between sleep duration and several markers of SES (education, monthly income, and nationality).

METHODS: Adults of a representative sample of the Geneva population were recruited. Self-reported sleep duration was assessed by questionnaire, where the participants indicated the usual time they went to bed and they woke up.

RESULTS: The analysis included 3853 adults (50 % women, 51.7 ± 10.9 years). After adjusting for survey year, sleep duration was higher among elderly subjects (adjusted mean \pm SE: 7.67 ± 0.02 , 7.82 ± 0.03 and 8.41 ± 0.04 h/day for age groups [35–50], [50–65] and [65+ years, respectively, p <0.001], and lower in participants who were foreigner (7.77 ± 0.03 vs. 7.92 ± 0.03 h/day for Swiss nationals, p <0.001), with higher education (7.92 ± 0.02 for non-university vs. 7.74 ± 0.03 h/day for university, p <0.001) or higher income (8.10 ± 0.04 , 7.84 ± 0.03 and 7.70 ± 0.03 h/day for <5'000 SFr; 5'000–9'500 SFr and >9'500 SFr, respectively, p <0.001). Similar associations were found for prevalence of sleep <8 h/day or after multivariate adjustment, except that the association with education was borderline significant (p =0.065). Finally, no significant trend was found both for reported sleep time (7.7 ± 1.1 in 2005 vs. 7.8 ± 1.1 h/day in 2011, p =0.36) or the prevalence of sleep <8 h/day, and no interaction was found between SES markers and study year.

CONCLUSIONS: Income, more than education, is negatively and positively associated with sleep duration and short sleep in the Geneva population. No change in sleep duration and short sleep was observed from 2005 to 2011.

EXPLORING THE ASSOCIATION BETWEEN PATIENT-CENTERED MEDICAL HOME TEAM-BASED CARE ELEMENTS AND EMPLOYEE JOB SATISFACTION AT THE VHA

*Ian A. Randall^{1,2}; Henry B. Harvey²; David Mohr^{3,4}; Emily D. Dolan^{1,2}; Karin M. Nelson^{1,5}; Paul Hebert^{1,5}; Stephan D. Fihn^{5,6}; Christian Helfrich^{1,2}.
¹University of Washington, Seattle, WA; ²VA Puget Sound Healthcare System, Seattle, WA; ³VA Boston Healthcare System, Boston, MA; ⁴Boston University, Boston, MA; ⁵VA Puget Sound Healthcare System, Seattle, WA; ⁶Veterans Health Administration, Seattle, WA.* (Tracking ID #1938409)

BACKGROUND: The Veterans Health Administration (VHA) implemented a patient-centered medical home (PCMH) model, termed Patient Aligned Care Teams (PACT), in 2010. We explored how various team-based care elements of this organization-wide implementation and other employee- and clinic-level covariates were associated with employee job satisfaction.

METHODS: We analyzed a cross-sectional, web-based survey of VHA employees from May 2012 and VHA administrative data. Overall job satisfaction was scored on 5-point scale from "Not at all satisfied" to "Very satisfied" and modeled using multivariate linear regression. PACT team-based care elements that are characteristic of either the presence or absence of an implemented PCMH model were tested for associations with employee job satisfaction.

RESULTS: 4,565 VHA primary care employees, including primary care providers (physicians, physician assistants and nurse practitioners), nurse managers, clinical assistants and clerks from 536 different primary care clinics responded to the survey. Results presented below are coefficients representing the estimated linear change on the 1–5 job satisfaction outcome scale (e.g., a β of 0.5 represents an estimated job satisfaction outcome that is 0.5 points higher). Among PACT characteristics, participatory decision-making (i.e., giving PACT team members a voice in decisions about how the team operates) was associated with higher job satisfaction ($s=0.36$, 95 % CI: 0.21, 0.52), while a chaotic or stressful work environment ($\beta=-0.49$, 95 % CI: -0.59, -0.40) and spending time on tasks someone with less training could do ($\beta=-0.15$, 95 % CI: -0.24, -0.05) were associated with lower job satisfaction. Among employee-level covariates, being a Team Leader ($\beta=0.13$, 95 % CI: 0.04, 0.21), Supervisor ($\beta=0.36$, 95 % CI: 0.16, 0.55) or Manager ($\beta=0.57$, 95 % CI: 0.39, 0.76) were associated with higher job satisfaction compared to having no supervisory responsibility. Being a nurse ($\beta=0.17$, 95 % CI: 0.06, 0.28), clinical associate ($\beta=0.46$, 95 % CI: 0.34, 0.57), or administrative clerk ($\beta=0.22$, 95 % CI: 0.08, 0.35) were associated with higher job satisfaction compared to PCPs. Spending more than 80 % of one's time in primary care ($\beta=-0.21$, 95 % CI: -0.39, -0.03) was associated with lower job satisfaction. Having VA tenure of 1–2 years, 2–5 years, 5–10 years, 10–15 years, 15–20 year or more than 20 years was associated with lower job satisfaction, compared to having VA tenure less than 6 months. Among clinic-level covariates, working in a clinic with a higher mean patient comorbidity (as measured by mean DCG score) was associated with higher job satisfaction ($\beta=0.14$, 95 % CI: 0.06, 0.22), while working in a VA Medical Center-affiliated clinic was associated with lower job satisfaction ($\beta=-0.11$, 95 % CI: -0.20, -0.03).

CONCLUSIONS: Some PACT characteristics hypothesized to correlate with job satisfaction were associated with overall job satisfaction after adjusting for employee- and clinical-level covariates. Participatory decision-making was associated with higher job satisfaction while working in a chaotic or stressful environment and working below one's competency were associated with lower job satisfaction. Results indicated that job satisfaction may be lower among PCPs, longer-tenured VA employees and primary care personnel, posing potential long-term challenges to the sustainability of the PACT model and retention of key personnel.

EXTENT AND PREDICTORS OF TRAINING IN OFFICE-BASED TREATMENT OF OPIOID ADDICTION IN U.S. RESIDENCY PROGRAMS: A NATIONAL SURVEY OF PROGRAM DIRECTORS Lello Tesema; Jeffrey Marshall; Rachel Hathaway; Christina Pham; Camille Clarke; Genevieve Bergeron; James Yeh; Michael Soliman; Danny McCormick. Cambridge Health Alliance and Harvard Medical School, Cambridge, MA. (Tracking ID #1938929)

BACKGROUND: Opioid addiction (OA) is a public health epidemic and is associated with a high mortality rate. Highly effective pharmacotherapies to treat OA exist, but less than 15 % of those in need of treatment receive it. While methadone and buprenorphine are the gold standard treatments for OA, buprenorphine alone can be prescribed in office-based settings, potentially providing greater access. Prescription of buprenorphine in ambulatory medical practice is uncommon, however, potentially due to limited instruction of physicians during residency training. However, little is known about the extent to which residency programs provide training in the prescribing of buprenorphine or the treatment of OA.

METHODS: We conducted an email based survey of all U.S. residency program directors (RPD) in Family Medicine, Internal Medicine and Psychiatry that were listed on the website of the American College of Graduate Medical Education (ACGME). Survey items assessed the extent of program training in the use of buprenorphine, in addictions medicine generally, and whether or not residents were required or encouraged to obtain a Drug Enforcement Administration buprenorphine waiver (required to prescribe this medication). We also assessed program directors' views and attitudes regarding the use of buprenorphine and potential barriers to

buprenorphine training. We produced descriptive statistics for all items and also compared responses of RPD across the three program types. We also examined the relationship between RPD views of the value of buprenorphine and the extent of program training in buprenorphine by calculating odds ratios of 95 % confidence intervals.

RESULTS: Of the 947 RPD we surveyed, 471 responded (49 % response rate). The majority of RPD report that their residents frequently manage patients with opioid addiction (77 %), believe buprenorphine is an important treatment option for opioid dependence (88 %), and believe increased residency training in buprenorphine would expand access to care for OA patients (73 %). Yet a minority of programs train residents in the use of buprenorphine (36 %), require or encourage residents to obtain a waiver (23 %) or dedicate greater than 12 h (over 3 years) to formal training to addiction medicines (23 %), although psychiatry programs were more likely to do so (data not shown) A minority also believed that prescribing buprenorphine should be a core competency (37 %) of their discipline. We also found that RPD belief that buprenorphine is an important treatment option for OA was associated with a greater odds of the program providing training in buprenorphine (3.5 [CI95% 1.6–7.4]). The most frequently cited barriers to implementing buprenorphine training in residency programs included: shortage of licensed preceptors (77 %), competing curricular priorities (64 %), and lack of support services (54 %).

CONCLUSIONS: Most residency programs frequently care for OA patients and most RPD believe in the effectiveness of buprenorphine and its ability to expand access to treatment for OA. Yet only a minority of training programs offer formal training in the treatment of OA generally, or with buprenorphine specifically. Increasing the exposure of physicians during residency training to ambulatory treatment of OA using buprenorphine could promote greater access to this treatment option.

EXTERNAL VALIDATION OF A SCORING SYSTEM THAT PREDICTS READMISSION OF PATIENTS WITH ACUTE PANCREATITIS TO THE HOSPITAL WITHIN THIRTY DAYS OF DISCHARGE Mohammed Aljasmi; Aymen Bukannan; Yathreb Alaali; Ahmed Saeed; Gregory Buran. Henry Ford Hospital, Detroit, MI. (Tracking ID #1939127)

BACKGROUND: Acute pancreatitis (AP) is one of the medical conditions that cause a heavy financial burden on the American health care system, in addition to causing significant morbidity to patients. Studies have estimated that the average cost of hospitalization for acute pancreatitis ~\$10 k, and acute pancreatitis is responsible for about \$2.2 billion in US health care expenditure annually. Studies have shown that the rate for early readmission for acute pancreatitis was found to be close to 20 %. Our aim was to validate a recently published scoring system to predict readmission of patients with acute pancreatitis to the hospital within 30 days of discharge.

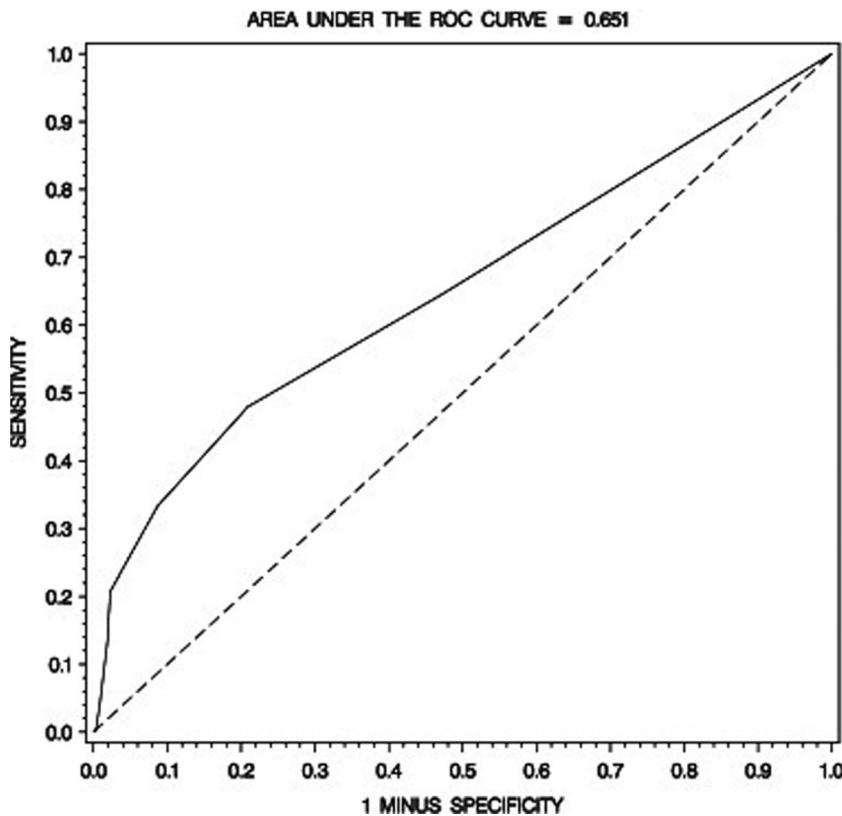

METHODS: A Retrospective review of patients with AP admitted to Henry Ford Hospital from October 2008 to December 2010. Inclusion and exclusion criteria reflected that of the original study. Diagnosis of AP required two of the following: characteristic abdominal pain, serum amylase/lipase more than or equal to three times the upper limit of normal, or CT of the abdomen within the first 7 days of hospitalization demonstrating changes consistent with AP. Factors of the scoring system were analyzed at time of discharge including eating less than solid diet; GI symptoms; pancreatic necrosis; antibiotics; pain. Results were analyzed using Logistic regression modeling and a ROC curve to evaluate the strength and performance of the scoring system.

RESULTS: There was 380 patient admitted during the study period with 47 being readmitted within the 30 day period for a readmission rate of 12 %. An odd ratio of 1.381 (p -value <000.1) indicate that each single unit increase in the risk score corresponds to approximately a 1.381 times increase in the likelihood of 30-day readmission within both settings. The resulting ROC curve areas 0.66 indicate that the risk score is a moderate predictor of 30-day readmission.

CONCLUSIONS: Our findings suggest that the "SNNAP" scoring system was predictive of 30-day readmission.

Comparison in 30 day readmission in patients who are low, moderate and high risk for readmission

	Readmission with 30 days	N
Risk Score <2	24 (8 %)	287
Risk Score 2–3	7 (15 %)	47
Risk Score ≥4	16 (35 %)	46
	47 (12.4 %)	380

FACTORS ASSOCIATED WITH LOSING AT LEAST 75 % OF GESTATIONAL WEIGHT GAIN BY EARLY POSTPARTUM IN WOMEN WITH RECENT GESTATIONAL DIABETES Jacinda M. Nicklas^{1,2}; Chloe A. Zera³; Sue E. Levkoff^{4,5}; Ellen W. Seely². ¹University of Colorado School of Medicine, Aurora, CO; ²Brigham and Women's Hospital, Boston, MA; ³Brigham and Women's Hospital, Boston, MA; ⁴Brigham and Women's Hospital, Boston, MA; ⁵University of South Carolina, Columbia, SC. (*Tracking ID #1937893*)

BACKGROUND: Women with gestational diabetes (GDM) have a 30–70 % risk for developing type 2 diabetes (T2DM) later in life. Postpartum weight retention is highly predictive for future obesity, and further increases risk for T2DM. We sought to identify factors associated with losing at least 75 % of gestational weight gain by early postpartum in women with recent GDM.

METHODS: We recruited women with GDM during pregnancy or just after delivery. Pre-pregnancy weight was self-reported at recruitment; gestational weight gain, mode of delivery, and insulin use were extracted from medical records. At a mean of 7.2 (± 2.1) weeks postpartum we measured weight, height, and administered questionnaires, including: demographics, breastfeeding, sleep, Edinburgh Postnatal Depression Scale, Harvard Food Frequency, and the International Physical Activity Questionnaire. After conducting an analysis of univariates, we used backward selection to fit a multivariable logistic regression model for univariates with $p < .2$ to identify factors associated with losing 75 % or more of gestational weight gain by early postpartum.

RESULTS: Our study included 75 women (mean 33 ± 5 years; pre-pregnancy BMI $31.4 (\pm 5.6)$ kg/m 2 ; 57 % White, 29 % African-American, 15 % Asian, with 20 % identifying as Hispanic and 34 % low income). Mean pregnancy weight gain was 12.5 kg (± 7.8). Fifty-two percent of participants lost at least 75 % of their pregnancy weight gain by the study visit. Dietary composition, fiber intake, added sugars, and glycemic index were similar between those who demonstrated early weight loss and those who did not, and consequently were not included in the multivariate model. Physical activity, sedentary time, race/ethnicity, education, income, mode of delivery, postpartum depressive symptoms, and breastfeeding were also similar between groups and not included in the model. In a multivariate model adjusting for weeks postpartum, only increased age (OR 1.31; 95 % CI 1.06 to 1.76 per year) and less gestational weight gain (OR 0.63; 0.48 to 0.76 per kg) were associated with at least

75 % early postpartum weight loss. Insulin use, nulliparity, and sleep were not retained in the model.

CONCLUSIONS: A substantial proportion of women with recent GDM lost at least 75 % of their gestational weight gain by early postpartum. Older women and those who had gained less weight during pregnancy were significantly more likely to have lost at least 75 % of gestational weight. Limiting gestational weight gain may help women with GDM return to pre-pregnancy weight quickly during the postpartum period.

FACTORS ASSOCIATED WITH PATIENT'S VIEW ABOUT DISAPPEARANCE OF THEIR CHRONIC PAIN Michel P. Kossovsky¹; Valerie Piguet²; Christine Cedraschi¹; Anne-Francoise Allaz¹. ¹Geneva University Hospitals, Geneva, Switzerland; ²Geneva University Hospitals, Geneva, Switzerland. (*Tracking ID #1935509*)

BACKGROUND: Chronic pain is a frequent complaint among internal medicine patients. One important aspect in the care of such patient is to understand how they apprehend the manifestation of the pain and what they expect for the future. The aim of our study was to investigate the variables associated with chronic pain patients' expectations about the possibility of pain disappearance.

METHODS: A self-administered questionnaire was given to all patients referred to our pain centre over a 2 year period. Patients were asked about the likelihood of pain disappearance (dichotomic answer: possible/probable vs. unlikely/impossible). Multivariate logistic linear regression analysis evaluated which variables were associated with the likelihood of pain disappearance. The model was controlled for age and gender, the presence of depression (evaluated with the Beck Depression Inventory), anxiety (evaluated by the Hospital anxiety and depression scale), present pain intensity (evaluated on a visual analog scale (0–10 cm)), duration of chronic pain, attribution of pain origin (extrinsic, intrinsic or undetermined) and perceived level of illness on a 4 level scale (from considerably to not at all).

RESULTS: We collected information on 437 patients. Mean age was 53; women were 284 (65 %). Table represents the odds-ratios associated with patients' estimation of the likelihood of pain disappearance.

CONCLUSIONS: Neither age nor sex were associated with likelihood of pain disappearance according to patients. Interestingly, pain intensity, anxiety or causal attribution were not either associated with likelihood of pain disappearance. Depression, a longer duration of chronic pain and a higher perceived level of illness

were significantly associated with a reduced likelihood of pain disappearance. Practitioners confronted with chronic pain patients should be aware that these three

variables are linked with patients' views about the future of their pain and taken into account when planning the treatment.

Variable	Odds-ratio	95%CI	p value
Age (for each year)	1.00	0.99 – 1.02	0.41
Sex (F vs. M)	1.08	0.66 – 1.77	0.75
Anxiety (for each point)	0.99	0.93 – 1.06	0.91
Depression (for each point)	0.97	0.94 – 0.99	0.01
Causal attribution			
Extrinsic vs. Intrinsic	0.69	0.38 – 1.24	0.22
Undetermined vs. Intrinsic	1.07	0.61 – 1.89	0.80
Present pain intensity (for each point)	1.03	0.93 – 1.14	0.56
Duration of chronic pain (per year)	0.96	0.93 – 0.99	0.003
Perceived level of illness			
Somewhat vs. Considerably	1.98	1.07 – 3.71	0.03
Lightly vs. Considerably	2.21	0.96 – 5.08	0.06
Not at all vs. Considerably	2.98	1.12 – 7.88	0.03

FACTORS ASSOCIATED WITH THE DECISION TO UNDERGO CONTRALATERAL PROPHYLACTIC MASTECTOMY AT THE TIME OF A BREAST CANCER DIAGNOSIS Kyungsuk Jung^{1,2}; Kala Visvanathan². ¹Presence Saint Francis Hospital, Evanston, IL; ²Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD. (*Tracking ID #1921712*)

BACKGROUND: Increasing number of breast cancer patients are electing for contralateral prophylactic mastectomy (CPM) to prevent contralateral breast cancer. CPM was shown to be associated with a survival advantage in women with BRCA1/2 mutation carriers, thus at high risk of developing breast cancer with a life expectancy gain of 0.6–2.1 years. This study sought to identify factors that may affect the decision of breast cancer patients to undergo CPM.

METHODS: A cohort of >1200 women who are at high risk of developing breast cancer were recruited primarily from the high risk clinic. Women with either positive family history of breast or ovarian cancer, positive BRCA1/2 gene or <40 years of age were eligible for inclusion. From this cohort, 370 women diagnosed with breast cancer were identified. All study participants had completed a Questionnaire that included—demographic, disease history, surgical history, lifestyle factors extensive family history of cancer, and genetic testing. Pearson's χ^2 test, univariable analysis and multivariable analysis were used to compare characteristics in both groups.

RESULTS: 81/370 patients with unilateral breast cancer, chose to have a CPM. Univariable analyses showed that younger patients were significantly more likely to undergo CPM (OR, 0.93; 95 % CI, 0.91–0.96). Patients were also significantly more likely to undergo CPM if they had bilateral oophorectomy (OR, 2.18 95 % CI, 1.22–3.87), deleterious result from BRCA test (OR, 1.87, 95 % CI, 1.00–3.49), had breastfeeding experience (OR, 2.96, 95 % CI, 1.28–3.20) and had a positive family history of breast cancer in 1st and 2nd degree relative (OR, 2.75, 95 % CI, 1.22–6.17). Multivariable logistic regression analysis with significant variables from the above outcome revealed that patients who were younger (OR, 0.92, 95 % CI, 0.89–0.97), had bilateral oophorectomy (OR, 2.63, 95 % CI, 1.18–5.89), had a positive family history of breast cancer in 1st & 2nd degree relative (OR, 4.36, 95 % CI, 1.40–13.60) were more likely to choose to undergo CPM. BRCA testing, BRCA test result, marital status, menopausal status and breastfeeding experience were not significantly associated with the use of CPM.

CONCLUSIONS: Younger age is the strongest determinant of undergoing CPM in women at high risk for breast cancer which is consistent with their higher risk of a second breast cancer. For women with family history of breast cancer, it is important to identify their genetic risks to help with their decision. History of oophorectomy was also associated with CPM. However, oophorectomy is reported to be a negative factor on the risk of developing CBC. Evidence-driven models are needed to better inform patients.

FACTORS ASSOCIATED WITH UNCONTROLLED HYPERTENSION IN AN URBAN ACADEMIC PRIMARY CARE CLINIC POPULATION Yaakov Y. Liss; Jonathan Arend; Georgia Giebel; Lauren Peccoralo. Mount Sinai School of Medicine, New York, NY. (*Tracking ID #1922682*)

BACKGROUND: Despite innumerable anti-hypertensive medication treatment options, only 70 % of Americans receiving treatment have controlled hypertension. Emerging data demonstrates that using a panel-based approach can dramatically improve hypertension control for a clinic population. However, little data exists on factors associated with uncontrolled hypertension within an urban academic primary care clinic population. Identifying such factors is crucial for designing a hypertension panel management program that will succeed in improving hypertension control for this population. This pilot study aims to identify factors related to uncontrolled hypertension in an urban academic primary care clinic population including patient demographics, co-morbid disease status, specific medication use, and disease control measures, as well as to identify visit specific factors that may contribute to hypertension control.

METHODS: Data included in this study is from a convenience sample of all patients with a diagnosis of hypertension seen in an urban academic primary care clinic on October 1, 2013. Data was obtained using the reporting workbench function of the clinic's Electronic Medical Record (EMR) system. Predictor variables included patients' sex, ethnicity, race, age, preferred language, marital status, last blood pressure, BMI, presence of diabetes, CHF, CAD, or asthma, ace inhibitor use, beta blocker use, hemoglobin A1C, LDL, and GFR. The outcome variable of uncontrolled hypertension was dichotomized and defined as uncontrolled if the last blood pressure reading performed in an ambulatory setting exceeded 140/90. For categorical non-numeric predictor variables, a chi square test was used to determine an association with blood pressure control, and for continuous predictor variables, a one-way anova test was used. Using the same methods as above, data for all hypertensive patients (>5000) seen in the clinic over a 1-year period will be recorded and analyzed. Additionally, a chart review was performed of 32 randomly selected patients with uncontrolled hypertension to identify the management plan. Eventually, 200 charts will be reviewed by two investigators, with a 3rd investigator to resolve discrepancies.

RESULTS: Based on the convenience sample described above, 261 patients were identified, 40 % of whom had uncontrolled hypertension. Baseline demographic data of the 261 patients identified can be found in Table 1. There was a statistically significant association with gender and uncontrolled hypertension (73 % males uncontrolled versus 27 % females uncontrolled, $p=0.0001$), and with race-ethnicity and uncontrolled hypertension (Non-Hispanic African American descent versus Hispanic Non-African American descent versus Non-Hispanic Non-African American Descent, 51 % versus 35 % versus 25 %, $p=0.008$). There were no other statistically significant associations. The results of the chart review demonstrated seven common scenarios and management plans (or lack thereof) during the visit when the last (uncontrolled) blood pressure measurement was taken. These are described and quantified in Table 2.

CONCLUSIONS: This study demonstrated significantly worse hypertension control in African American patients and male patients, results that differ significantly from recent national trends where Hispanic and female patients were noted to have worse hypertension control. It is unclear why this discrepancy exists and whether these results are specific to this clinic population or are reflective of a broader trend in urban academic primary care clinics. Additionally, the identification of seven management plans occurring during the patient-doctor interaction presents several different possibilities of interventions that may improve overall hypertension control in this clinic population. Among these are instituting a policy encouraging providers to schedule patients with uncontrolled hypertension for follow up within 1 month; EMR alerts to a patient's primary doctor when an elevated blood pressure is recorded by a consultant; and a system to remind patients of upcoming appointments.

Table 2. Patient Doctor Interaction Scenarios

BP Management Plans	Number of Occurrences	Percentage
BP normal or near normal- no need for intervention	6/32	19 %
BP elevated, meds adjusted, Pt pending f/u within 1 month	3/32	9 %
BP elevated, meds adjusted, Pt referred for f/u >1 month	5/32	16 %
BP elevated, meds adjusted, Pt referred for f/u within 1 month, Pt never came in	8/32	25 %
Elevated BP recorded during consultant visit- BP not addressed during visit	6/32	19 %

FACTORS INFLUENCING MEDICAL STUDENT USE OF ELECTRONIC HEALTH RECORDS: A NEEDS ASSESSMENT Dylan Sherry; Megan S. McNamara. Case Western Reserve University, Cleveland, OH. (*Tracking ID #1934496*)

BACKGROUND: Physicians are increasingly using Electronic Health Records (EHRs) in their daily practice, but there is a lack of formalized training about EHRs in most medical school curricula. Education in the use of EHRs for medical students has typically been unofficial "on the job" training by superiors or "how-to" online modules which focus on how to accomplish a specific task using the EHR, such as documenting a history and physical, or writing a progress note. These narrow approaches may lead students to consider the EHR as merely a repository of information, rather than a system which can potentially improve physician workflow and patient care. In order to design effective curricula for medical students, we conducted a needs assessment to understand how students are currently using the EHR and what factors influence their use.

METHODS: We developed a seven-item electronic questionnaire which surveyed students about how they would use the EHR in a particular clinical scenario. Each item was associated with a list of potential responses, and students were asked to justify their choice through a written explanation. The clinical scenarios were developed using the RIME educational framework (Reporter-Interpreter-Manager-Educator) approach to EHR education. We mapped each question to both a RIME category and to ACGME core competencies. For example, a question about whether or not a student might copy and paste a previous day's progress note to save time would be mapped to the RIME category "Reporter" and to the ACGME core competency "Professionalism." In order to ensure content validity we sent the questionnaire to 10 national informatics experts for recommendations and made suggested changes. All Case Western Reserve University students were eligible for participation and were recruited via email invitation.

RESULTS: The questionnaire was sent to 495 medical students (Preclinical, Core Clerkships, Elective/Acting Internship) with a 39 % return rate. Using a framework analysis approach we identified 11 specific factors which influence students' use of the EHR. These included efficiency, communication tool, accuracy of documentation, influence on physician/patient communication, trusting the EHR, intrusive, role modeling, familiarity with the EHR, habit, advancing learning, and impediment to learning. For example, efficiency was a factor that drove students to use templates or copy and paste. Influence on physician/patient communication was a factor which determined how, if at all, the EHR was used during a clinical encounter. These factors could be broadly grouped into how students view the positive and negative aspects of the EHR as it relates to patient care, how students learn about the EHR, and how the EHR influences their medical education overall. The following exemplar quotes help to illustrate why medical students chose to use the EHR in certain ways: "Flipping through fill-in-the-blanks is fastest, but it makes me feel like a robodoctor. I would rather write it out to really make myself learn it, but when you don't have much time, [templates] are the best." Core Clerkship Student "I like to be able to shape my differential in my head without a pre-conceived notion of what is important. When I am entering it [in the EHR] afterwards, I am happy that there are templates available so I can be reminded of what I may have missed." Core Clerkship Student "I [copy and paste] for efficiency in tracking the patient, not just to save time. I like having my note in the same essential format from 1 day to the next so that my eye can scan quickly to pertinent changes. I can quickly see how many days an antibiotic has been taken, which consults have returned recommendations, etc. If I wrote each note from scratch I would have to read the entire thing the next day to find what I wanted to know." Core Clerkship Student "Copy/pasting is dangerous and can lead to incorrect information in the chart. Always start from scratch and you'll never be inaccurate. Reference old notes to ensure you're not missing anything, but don't copy paste." Elective/Acting Internship Student

CONCLUSIONS: Medical students are quite aware of the positive and negative impacts that the use of EHRs can have on patient care and on medical education. These factors could be used as a springboard for EHR education. Alongside the

current how-to focus, education could be enhanced by addressing student's concerns about the potential negative impacts of the EHR, such as copy and pasting or interrupting the clinical encounter. Student decision-making regarding EHR use suggests that future EHR education should be placed more in the context of clinical medicine to help students learn to mitigate negative effects on medical education and on patient care.

FACULTY PERCEPTIONS OF COMPETENCY-BASED EVALUATION OF MEDICAL STUDENTS Elizabeth Karwowski^{1,2}; Elizabeth Sandman²; Jane M. Liebschutz¹; Bruce Fraser³; Jay D. Orlander^{2,1}. ¹Boston University Medical Center, Boston, MA; ²Boston VA Healthcare System, Boston, MA; ³Boston University School of Education, Boston, MA. (*Tracking ID #1938972*)

BACKGROUND: The Accreditation Council for Graduate Medical Education (ACGME) transitioned to competency-based evaluation with its Outcome Project in 1999. The Liaison Committee on Medical Education (LCME) adopted the same core competencies to evaluate medical students: medical knowledge, patient care, interpersonal communication, professionalism, practice-based learning and improvement, and systems-based practice. In May 2012 Boston University School of Medicine changed all student clerkship evaluation forms to a standardized, competency-based format. Little is known about faculty perception of the use of the core competencies to evaluate medical students or their process of student evaluation.

METHODS: Semi-structured, one-on-one interviews were conducted with Department of Medicine physician faculty. Eligibility criteria included evaluating six or more third and/or fourth year clerkship students per year in any clinical setting. Interview questions explored types of faculty interaction with students, faculty attitudes toward student evaluation, and faculty attitudes towards evaluating medical students using the ACGME core competencies. All interviews were transcribed verbatim. Co-investigators reviewed transcripts and identified common themes using Grounded Theory. Two separate investigators coded interviews and achieved consensus on the themes present, resolving discrepancies through discussion. The remaining three co-investigators, with more qualitative experience, checked the final coding schemes for accuracy.

RESULTS: Twelve faculty members with a range of clinical responsibilities (primary care, hospitalist, specialist) and experience participated in the study. All faculty acknowledged that their evaluations were limited due to a lack of direct observation for many competencies. The majority primarily observed case presentations and used these as a proxy for areas they were unable to observe. One faculty commented: "the majority of my evaluation is gonna be based on how they presented the patient to me... so, even if I'm not observing how they're getting the data, if they come back and they've got pretty good data... I can technically check these off [evaluation questions on global assessment form]." For competencies, such as systems based practice, faculty had few, if any, objective or measurable activities to evaluate. Faculty identified multiple barriers to student evaluation including time, other learners, patient care responsibilities, and lack of training in evaluation methods. Faculty expressed significant tension over the evaluation process. They contrasted a sense of inadequacy in their ability to reliably evaluate students with a heightened awareness of the significance of their evaluations in determining student grades. In particular, faculty felt they could identify and evaluate students at the extremes of performance but struggled with discriminating between students in the middle. One faculty commented: "I feel like... there's not enough ability to distinguish [between students], just using this scoring system. And... presumably, that's the intent." The purpose and ramifications of medical student evaluation were not well understood: does evaluation certify that a student is competent or does it provide a means of stratification between students? Often this resulted in self-reported grade inflation.

CONCLUSIONS: Competency-based evaluation on the clinical clerkships presents a challenge to many experienced faculty members. Faculty development around student evaluation that explicitly addresses student milestones and expectations, purpose of evaluation, and feedback on an individual's grading practices may be beneficial in improving the process. Given the frequency at which it seems to occur, further work needs to elucidate the association of presentation skills as a proxy for other clinical skills.

FAILING TO CHOOSE WISELY: LACK OF TREATMENT DE-INTENSIFICATION IN OLDER PATIENTS WITH DIABETES Eve A. Kerr^{1,2}; Rob Holleman¹; Mandi L. Klamerus¹; Sameer D. Saini^{1,2}; Lillian Min^{1,2}; Sandeep Vijan^{1,2}; Jeremy Sussman^{1,2}; Timothy Hofer^{1,2}. ¹VA Center for Clinical Management Research, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI. (*Tracking ID #1936536*)

BACKGROUND: It is increasingly recognized that efforts to intensively improve hemoglobin A1c (A1c) and blood pressure (BP) control in patients with diabetes sometimes unintentionally result in overtreating patients who are unlikely to benefit. Recent guidelines and initiatives like Choosing Wisely recommend less aggressive treatment for older patients with limited life expectancy (LE), since such treatment is unlikely to improve outcomes and may cause harm. This suggests that medication de-intensification is indicated among many patients with limited LE. Yet, we know little about how often providers decrease treatment intensity among patients who are unlikely to benefit. We examined how often the number or dose of medications are decreased in older patients with diabetes and lower than recommended levels of A1c or BP, and whether medication de-intensification is more common in patients with lower LE.

METHODS: Using the Veterans Health Administration's (VHA) Corporate Data Warehouse, we identified all patients with diabetes, age 70 and older, receiving primary care in VHA during 2012. We then identified the patients' last A1c and BP during 2012, and their prescribed medications at the time of this index A1c or BP. Patients with A1c<6.5 % and on hypoglycemic medications (other than metformin alone) were considered eligible for de-intensification. Patients with BP<130/65 and on BP medications (other than low dose angiotensin converting enzyme inhibitor (ACEI) alone or low dose angiotensin receptor blockade (ARB) alone) were similarly eligible. We determined the proportion of patients who had medications discontinued or had the dose decreased in the 6 months after the index A1c or BP. Using logistic regression, we examined the association between limited LE, based on the Charlson comorbidity index, and de-intensification, controlling for number of medications the patient was taking at the time of the index A1c or BP.

RESULTS: 500,742 patients with diabetes, age 70+, were receiving primary care in VHA during 2012. Among the 114,411 with A1c<6.5 %, 51 % were on no medications, 15 % were on metformin only, 8 % were on insulin only, 14 % were on sulfonylureas only, and 12 % were on other or combination therapy. Among the 36,686 eligible for de-intensification, 8,466 (23 %) were de-intensified within 6 months. Patients with LE<5 years were modestly more likely to be de-intensified than those with LE>10 years (predicted probability 29 % vs 19 %, $p<0.001$). Among the 66,750 patients with a BP<130/65, 10 % were on no medications, 6 % were on low dose ACEI or ARB only, 22 % were on 1 BP medication, and 62 % were on 2 or more BP medications. Among those eligible for de-intensification, 9,883 (21 %) were de-intensified. Patients with LE<5 years were somewhat more likely to be de-intensified than those with LE>10 years (predicted probability 24 % vs 17 %, $p<0.001$).

CONCLUSIONS: Despite increasing awareness that overtreatment of diabetes may be harmful in older adults, less than one quarter of patients treated to levels significantly lower than recommended had medications de-intensified. While patients with limited LE were more likely to be de-intensified than those in good health, the majority of eligible older patients, even those with limited LE, continued to receive care that is of low value or potentially harmful. Future initiatives that seek to help patients and providers choose wisely will need to address this significant clinical inertia for de-intensification of treatment.

FEAR OF INDEPENDENCE LOSS (FOIL): OLDER ADULT PERCEPTIONS ON REFUSAL OF HOME CARE Vanessa Ramirez-Zohfeld¹; Kenzie A. Cameron¹; Priya Sunkara¹; Chris Forcucci²; Megan Huisingsh-Scheetz³; Lee Lindquist¹. ¹Northwestern University, Chicago, IL; ²Aging and In-Home Services of Northeast Indiana, Fort Wayne, IN; ³University of Chicago, Chicago, IL. (*Tracking ID #1935965*)

BACKGROUND: Remaining in one's own home is often one of the highest priorities of older adults. As their physical, functional, cognitive, and social needs increase, older adults may require more care in their home which they may illogically refuse. We sought to understand seniors' perceptions, in particular fears that they faced related to the potential loss of independence and refusal of accepting care in the home.

METHODS: We conducted eight focus groups with older adults (age 65 and older) living in rural, suburban and urban areas. Following a semi-structured interview guide, participants discussed advanced planning, decision-making, barriers, and resources that might have an impact on their ability to remain in their own home. We elicited participant's thoughts regarding losing independence. Three independent coders used content and constant comparative analysis to interpret results.

RESULTS: Sixty-eight older adults participated in the focus groups with a mean age of 73.9 years (SD=6.53); 50 (73.5 %) were female. Several major themes related to fear of independence loss (FOIL) as well as strategies to overcome FOIL emerged. FOIL was associated with loss of control, resentment of depending on others, annoyance with working around other people's schedules, as well as guilt of being

burdensome. One participant stated: "I had to depend on friends and neighbors to fix food or shop or do anything, and I thought, I don't want to be in that position." A feeling of burden, especially related to their children was a prominent theme across the focus groups with one participant stating: "I don't want to be a hinder. I don't want to stop their living. Because I have enjoyed my life and I want them to enjoy their life." Lack of trust in others and concerns about being exploited were also identified as reasons for FOIL: "At times, it seems like trying to get across a mine field avoiding exploitation from caregivers, from relatives and it is very disconcerting. Who can you trust?" Conversely, multiple participants re-framed the concept of independence and saw the actions as more inter-dependent. Someone noted that even if one becomes more limited over time, the recognition that one is still contributing something meaningful to society is important to overcoming FOIL: "I think we forget what the other person is contributing... the person who is able to see his grandchildren to smile at them; I mean he's giving them something as well." Another strategy presented to overcome FOIL was recognition that others may engender positive emotions by helping someone who is in need once they are less able to do so themselves: "When I'm on the receiving end, I've got to remember that that's giving somebody else some joy."

CONCLUSIONS: Older adults perceive fear of independence loss, which can impact their willingness to accept help. Addressing and promoting strategies to overcome this fear may aid in understanding how to assist seniors to obtaining and accepting needed home care, enabling them to remain safely in their own homes.

FINANCIAL BARRIERS TO CARE AMONG THE INSURED IN MASSACHUSETTS AFTER HEALTH CARE REFORM: DISPARITIES BY RACE, INCOME, AND HEALTH STATUS Sonali Saluja^{1,2}; Leah Zallman^{4,2}; Steffie Woolhandler³; David Himmelstein³; David Bor^{2,1}; Danny McCormick^{2,1}. ¹Harvard Medical School, Boston, MA; ²Cambridge Health Alliance, Cambridge, MA; ³City University of New York School of Public Health, New York, NY; ⁴Institute of Community Health - Cambridge Health Alliance, Cambridge, MA. (*Tracking ID #1936234*)

BACKGROUND: Massachusetts' 2006 Health Care Reform, the model for the Affordable Care Act (ACA), aimed to increase coverage and access to health care by making care more affordable, particularly for minorities, persons with low incomes and persons in poor health. Little is known about the post-reform prevalence of financial barriers to care among the insured in Massachusetts.

METHODS: We analyzed data from Massachusetts Behavioral Risk Factor Surveillance System, a representative statewide cross-sectional population-based survey of adults, pre-reform (2004–2005) and post-reform (2009–2010). The sample included adults ages 18 to 65 who reported having health insurance (2004–2005: $N=11,876$; 2009–2010: $N=21,782$). We considered respondents to have a financial barrier to care if they indicated that within the last 12 months they needed to see a doctor but could not because of cost. We compared rates pre and post-reform, overall and for racial/ethnic, income and health status groups. We used multivariate logistic regression models to assess the independent effect of race and income on financial barriers to care after adjusting for other covariates. Finally we examined the association between financial barriers to care and potential markers of need for care and utilization of care.

RESULTS: Among all non-elderly insured adults in Massachusetts, the proportion reporting a financial barrier to care did not change after state health care reform (pre-reform: 5.8 %, post-reform: 6.0 %; $p=0.60$). However, the proportion citing such a barrier rose 37.9 % (from 9.5 to 13.2 %; $p=0.004$) among low-income individuals (incomes \$15,000–\$34,999)—many of whom acquired subsidized insurance requiring copayments for physician visits under the reform. Post-reform, financial barrier rates varied by race and income group—with the highest rates in low-income minority individuals. Among persons with incomes below \$15,000, 24.9 % of Blacks and 24.2 % of Hispanics reported financial barriers vs. 9.8 % of Whites ($p=0.011$). In multivariate analyses, lower income individuals reported more financial barriers than those with incomes over \$50,000 ($\sim \$15,000$: OR=5.68 95%CI=5.61–5.74, \$15,000–\$34,999: OR=4.91; 95%CI=4.87–4.95, \$35,000–\$49,999: OR=3.43; 95%CI=3.40–3.47) as did minorities compared to Whites (Black: OR=1.18; 95%CI=1.16–1.19, Hispanic: OR=1.45; 95%CI=1.43–1.46). Individuals reporting financial barriers were less likely to have a primary care provider (RR=0.91; 95%CI=0.86–0.95) and to have a routine health care visit in the last year (RR=0.89; 95%CI=0.83–0.95), but were more likely to have two or more chronic health conditions (RR=1.26; 95%CI=1.10–1.44) and much more likely to be in poor or fair health (RR=3.13; 95%CI=2.63–3.77).

CONCLUSIONS: After full implementation of health reform in Massachusetts, financial barriers to care among Black, Hispanic and low-income residents are common and strongly related to worse health status. These findings raise concern

about the likely persistence of financial barriers to care nationwide after implementation of the ACA.

FINANCIAL INCENTIVES FOR COMPLETION OF FECAL OCCULT BLOOD TESTS AMONG VETERANS: A 2-STAGE PRAGMATIC CLUSTER RANDOMIZED, CONTROLLED TRIAL Jeffrey T. Kullgren¹; Tanisha N. Dicks²; Xiaoying Fu²; George L. Tzanis^{2,3}; Martin Tobi^{2,3}; Steven C. Marcus^{2,3}. ¹Ann Arbor VA Healthcare System and University of Michigan, Ann Arbor, MI; ²Philadelphia Veterans Affairs Medical Center, Philadelphia, PA; ³University of Pennsylvania, Philadelphia, PA. (*Tracking ID #1940020*)

BACKGROUND: Rates of primary care patient completion of prescribed fecal occult blood tests (FOBTs) are often low. A promising tool for improving rates of FOBT completion is financial incentives, which capitalize on insights from behavioral economics that suggest patients disproportionately weight near-term relative to distant costs and benefits. The objective of this study was to identify the dose and design of modest financial incentives that could increase rates of initial completion of prescribed FOBTs among Veterans Health Administration (VHA) primary care patients.

METHODS: We conducted a 2-stage pragmatic cluster randomized, controlled trial in the primary care clinics of the Philadelphia Veterans Affairs Medical Center. All 1,549 patients who were prescribed an FOBT during the study period were enrolled (i.e., there were unique samples of 713 patients in stage 1 and 836 patients in stage 2). In stage 1, patients were assigned to usual care or \$5, \$10, or \$20 for FOBT completion within 30 days. In stage 2, different patients were assigned to usual care or \$5, a 1 in 10 chance of \$50, or a \$500 raffle for FOBT completion within 30 days. The primary outcome was FOBT completion within 30 days. Secondary outcomes included time to FOBT completion and, among patients who had failed to complete a prescribed FOBT in the previous year, 30-day FOBT completion and time to FOBT completion.

RESULTS: In stage 1, \$5 (40.4 %, 95 % CI, 30.4 % to 51.3 %; $P=0.96$), \$10 (44.9 %, 95 % CI, 37.6 % to 52.3 %; $P=0.44$), and \$20 (45.3 %, 95 % CI, 38.4 % to 52.4 %; $P=0.38$) did not lead to a statistically significant increase in FOBT completion compared to usual care (40.7 %, 95 % CI, 33.3 % to 48.6 %). In stage 2, a 1 in 10 chance of \$50 led to a statistically significant increase (47.8 %, 95 % CI, 39.5 % to 56.3 %; $P=0.002$) but \$5 (38.9 %, 95 % CI, 29.5 % to 49.3 %; $P=0.15$) and a \$500 raffle (41.5 %, 95 % CI, 32.4 % to 51.2 %; $P=0.05$) did not lead to a statistically significant increase in FOBT completion compared to usual care (30.7 %, 95 % CI, 25.0 % to 37.0 %). In each stage there were no significant differences in time to FOBT completion and, among patients who had failed to complete a prescribed FOBT in the previous year, no significant differences in 30-day FOBT completion or time to FOBT completion.

CONCLUSIONS: Fixed payments of \$5, \$10, and \$20 did not increase rates of VHA patient completion of prescribed FOBTs within 30 days. However, when we tested 3 different financial incentive designs that shared a common upfront per patient allocation of \$5, we found that a 1 in 10 chance of \$50 was effective at increasing rates of FOBT completion within 30 days. Our finding serves as an example of a low-cost, scalable intervention that can improve health care quality by promoting patient adherence to a high-value clinical preventive service and adds to a growing evidence base supporting the effectiveness of financial incentives in improving health behaviors among VHA patients.

FINANCIAL ISSUES AND ADULT IMMUNIZATION: MEDICARE COVERAGE AND THE AFFORDABLE CARE ACT Laura Hurley^{1,2}; Megan C. Lindley⁴; Mandy Allison^{1,5}; Lori A. Crane^{1,6}; Michaela Brtnikova¹; Brenda Beaty^{1,3}; Megan Snow¹; Carolyn Bridges⁴; Allison Kempe^{1,5}. ¹Children's Hospital Colorado, Aurora, CO; ²Denver Health, Denver, CO; ³University of Colorado Anschutz Medical Campus, Aurora, CO; ⁴Centers for Disease Control and Prevention, Atlanta, GA; ⁵University of Colorado Anschutz Medical Campus, Aurora, CO; ⁶Colorado School of Public Health, University of Colorado, Denver, CO. (*Tracking ID #1935920*)

BACKGROUND: Financial barriers are often reported for adult vaccinations. The Affordable Care Act addresses some of these barriers; most notably by mandating private health plans to cover Advisory Committee on Immunization Practices recommended vaccinations with first-dollar coverage when delivered by in-network providers. The law does not change coverage of vaccines by Medicare: Medicare Part D, a pharmaceutical benefit, covers some vaccines, and Medicare Part B, a medical provider office-based benefit, covers others. Medicare part D has been seen as a barrier to physician-based vaccination. Our objectives were to assess among general

internists (GIM) and family physicians (FM): 1) how often vaccines are deferred or refused by adult patients for financial reasons 2) how often physicians reported not recommending an adult vaccine for financial reasons 3) knowledge of Medicare coverage of vaccines, and 4) awareness of vaccine specific provisions of the Affordable Care Act.

METHODS: We administered an Internet and mail survey from June to October 2013 to a national network of 438 GIM and 401 FM physicians representative of the American College of Physicians and American Academy of Family Physicians memberships. Descriptive analyses were performed.

RESULTS: Response rates were 72 % (317/438) for GIM and 59 % (236/401) for FM. Depending on the vaccine, 2–23 % of GIM and 5–30 % of FM reported adult patients defer or refuse vaccines due to financial reasons the majority of the time. The vaccines most commonly deferred or refused by patients for financial reasons were zoster and human papillomavirus vaccine for both specialties. Physicians in many instances reported they do not recommend vaccines when they thought a patient could

not afford it (GIM 4 % ‘frequently’, 16 % ‘sometimes;’ FM 5 % ‘frequently’, 20 % ‘sometimes’), when they thought a patient’s insurance would not cover the vaccine (GIM 9 % ‘frequently’, 24 % ‘sometimes;’ FM 12 % ‘frequently’, 24 % ‘sometimes’) and when they thought a patient could receive a vaccine more affordably elsewhere (GIM 9 % ‘frequently’ 30 % ‘sometimes;’ FM 11 % ‘frequently’, 26 % ‘sometimes’). The table shows physicians’ knowledge regarding Medicare coverage for vaccines. Over a third of physicians were unaware of provisions in the Affordable Care Act that promote vaccinations (GIM-39 %, FM-34 %) and one-fifth were only ‘a little aware’ (GIM-20 %, FM 17 %) of these provisions.

CONCLUSIONS: Patients are refusing and physicians are not recommending adult vaccinations for financial reasons. Increased knowledge of Medicare coverage would better enable physicians to direct older patients to the best venue to receive vaccines, particularly if their practice does not bill Medicare Part D. Heightened awareness of the favorable financial implications of the Affordable Care Act on vaccinations might result in physicians being more likely to recommend them.

Vaccine	Medicare coverage	Physicians who answered Medicare coverage question correctly (%)	
		GIM	FM
Hepatitis A	Part D	9	6
Hepatitis B	Part B	30	22
PCV13	Part B	44	35
PPSV23	Part B	53	53
Seasonal influenza	Part B	60	58

FIRST YEAR EXPERIENCE OF HCV SCREENING OF 2,765 BABY BOOMERS ADMITTED TO A SAFETY NET HOSPITAL IN SOUTH TEXAS

Barbara J. Turner^{2,1}; Barbara S. Taylor^{1,2}; Joshua T. Hanson^{1,2}; Mary E. Perez²; Ludivina Hernandez². ¹University of Texas Health Science Center at San Antonio, San Antonio, TX; ²University of Texas Health Science Center at San Antonio, San Antonio, TX. (Tracking ID #1935853)

BACKGROUND: Baby boomers account for over 75 % of the 3 to 5 million HCV-infected persons in the U.S., and 75 % of these HCV-infected persons are undiagnosed. The Centers for Disease Control and Prevention and the U.S. Preventive Services Task Force now both endorse one-time testing of all baby boomers (born 1945 to 1965) for hepatitis C virus (HCV) infection. Objective: To implement a baby boomer HCV screening and linkage to care program in the largest safety net hospital in South Texas.

METHODS: The program has 4 key features: 1) Education in English and Spanish about HCV screening of baby boomers using posters throughout the hospital and flyers in admission packets that offer an opt out option; 2) Electronic medical record algorithm that identifies eligible baby boomers and, for most, places an order for HCV antibody (HCV Ab) with a reflex HCV RNA test for positive HCV Ab [exclusion criteria: record of prior HCV test or diagnosis, poor prognosis (e.g. metastatic cancer), psychiatric admission]; 3) Personalized counseling for HCV Ab+ patients by a bilingual inpatient counselor who reviews a mobile app-based HCV educational program in English and Spanish that was developed by our team; and 4) Navigation by a bilingual community health worker to facilitate follow-up primary and HCV specialty care after hospital discharge by addressing barriers to care, poor health literacy, substance abuse, and lack of social support.

RESULTS: From 12/1/2012 to 11/30/2013, 5,572 unique baby boomers were hospitalized of whom 45 % were women, 59 % Hispanic, median birth year 1956, and 46 % uninsured. Of these, over 1,400 patients had a prior HCV test or diagnosis and were excluded. Of 2,765 unique baby boomers screened for HCV infection, 230 (8.3 %) tested HCV Ab+. HCV Ab+ was more likely for men (75 % vs. 55 % of HCV Ab negative, $p < .001$) but did not differ by birth year, Hispanic ethnicity, or insurance status. Follow-up HCV RNA testing was performed for 205 (89 %) of HCV Ab+ patients. 125 (61 %) were HCV RNA+ while 80 (39 %) were HCV RNA negative. HCV RNA positive and negative patients did not differ by birth year, gender, Hispanic ethnicity, or insurance status. Of the 125 patients diagnosed with chronic HCV infection, 110 (88 %) have been counseled, 100 (80 %) have had follow-up ambulatory care addressing HCV and 43 (34 %) have received HCV specialty care.

CONCLUSIONS: To our knowledge, this is the first baby boomer HCV screening program that has been broadly implemented in a civilian, safety-net hospital. The 8.3 % HCV Ab+ prevalence in persons without evidence of prior HCV testing or

diagnosis supports the public health value of screening in similar inpatient settings. This program has newly identified 125 patients with chronic HCV infection and linked the majority to follow-up ambulatory care. The high rate of apparent clearance of HCV (39 %) needs to be confirmed by repeat HCV RNA testing after 3–6 months. If confirmed, cost-effectiveness models may need to be adjusted to account for a lower proportion of HCV Ab+ baby boomers with persistent infection.

FOLLOW-UP OF ABNORMAL CT RESULTS Linda J. Canty¹; Paul Visintainer¹; Mihaela S. Stefan¹; Philip Henneman¹; Sean Stanhope¹; Reva Kleppel¹; Annie Lagoy¹; Jessilia Santiago¹; Michael B. Rothberg². ¹Tufts University School of Medicine / Baystate Medical Center, Springfield, MA; ²Cleveland Clinic, Cleveland, OH. (Tracking ID #1939790)

BACKGROUND: CT scans often include abnormal findings, and follow-up is frequently recommended. However, when a CT scan ordered in the emergency department (ED) or the inpatient unit contains an abnormal finding, it may not always be followed up by the primary care provider. Mechanisms in place to ensure the appropriate follow-up of tests may miss these types of handoffs. The objective of this study was to quantify the proportion of abnormal findings with follow-up and to assess factors associated with timely follow-up.

METHODS: We conducted a retrospective cohort study to assess the proportion of abnormal findings that had documented follow-up. The CT scans were performed at three hospitals within Baystate Health, a large health system in western Massachusetts. For the two community hospitals, we looked at all scans performed in 2010 on patients who also had a visit during 2010 to the primary care office associated with the hospital. For the academic medical center, we used a sample of two-thirds of the scans from January to mid-July 2010 performed on patients who had a visit during 2010 to one of six nearby primary care practices. All providers in the system have access to radiology readings through a shared electronic health record, but only for scans ordered in outpatient settings does the ordering provider receive the scan results in their electronic medical record inbox. CT scans involved the chest (including angiograms,) abdomen, pelvis or a combination of these. An abnormal result was defined as any finding for which the radiologist’s dictated final report recommended follow-up using wordings such as “recommend,” “suggest,” or “should be” followed, or cited guidelines outlining a timeframe for follow-up. For each of these findings, we used the electronic health record to assess whether the patient received appropriate follow-up, defined as either adherence to the radiologist’s suggestion or documentation that the finding was discussed and a conscious decision was made not to pursue the finding further. We compared the proportion of findings that received follow-up if they were ordered by outpatient providers to those ordered in the ED and inpatient wards.

RESULTS: We reviewed 1922 scans performed on 1524 patients. Overall, there was documentation of follow-up within the recommended time period in 176 out of 236 findings (75 %.) Of these, documentation of follow-up was seen in 41 of 64 (64 %) ED findings, 37 of 52 (71 %) inpatient findings, and 98 of 120 (82 %) outpatient findings. Follow-up was more common for findings on CT scans ordered by outpatient providers than for those ordered in the ED ($p=0.01$.) Findings on inpatients were not statistically more likely to be followed when compared to either the ED or the outpatient setting. Radiologists stating in the dictated report that the results were "communicated" was not associated with greater follow-up (44 of 56 findings; 79 %) compared to when this was not in the report (132 of 180 findings; 73 %; $p=0.49$.)

CONCLUSIONS: Abnormal findings on CT scans ordered in the outpatient setting were more likely to have documentation of follow-up than those ordered through the emergency department. For patients scanned in the ED, more than 1/3 of abnormal findings went without evidence of timely follow-up. Improved communication systems appear needed for radiological handoffs between the ED and the outpatient setting.

FOLLOW-UP PRIMARY CARE VISITS IN A RESIDENT PRACTICE AFTER HOSPITAL DISCHARGE - HOW ARE WE DOING? Sanjai Sinha¹; Thomas Uttaro³; Daniel M. Stein²; Amanda S. Carmel¹. ¹Weill Cornell Medical College, New York, NY; ²Weill Cornell Medical College, New York, NY; ³Weill Cornell Medical College, New York, NY. (Tracking ID #1935099)

BACKGROUND: Patients cared for in internal medicine teaching clinics often have poor primary care follow up after hospital discharge. Such discontinuity can result in medical errors, suboptimal care, and re-hospitalization. In a Medicare study, more than half of patients who were re-admitted within 30 days of hospital discharge had not had an outpatient encounter between admissions. Based on a 6-week period of inpatient and emergency department (ED) discharges from New York Presbyterian/Weill Cornell Medical Center (NYP/WCMC), we aimed to assess the percentage of Weill Cornell Internal Medicine Associates (WCIMA) patients that completed a post discharge appointment at WCIMA within 30 days of discharge. Secondarily, we examined the percentage of patients who utilized the hospital or ER more than once in the study period, and who saw their PCP for follow up.

METHODS: WCIMA is a large internal medicine practice affiliated with Weill Cornell Medical College in New York City. It is the main practice site for 33 faculty physicians and 136 internal medicine residents. Through data extraction of our electronic health records, we identified all WCIMA discharges from NYP/WCMC from 9/1/2013 to 10/12/2013. Information for each discharge including basic patient identifiers, age, payer, hospital department/ service, assigned primary care provider, completed visit date and provider were obtained. Interval between discharge and the follow up visit were calculated. The unit of analysis was a hospital discharge event, some patients had multiple hospitalizations and ED/urgent care visits. IBM SPSS software version 22 procedures for data manipulation and descriptive statistics were used for data analysis. IRB approval is pending.

RESULTS: We identified 1,908 unique discharges for 1,513 WCIMA patients from NYP/WCMC during the study period. Two hundred ninety-three patients (19.4 %) had more than one discharge. In WCIMA patients discharged from a Medicine admission, 51.2 % (N=259/506) had a post discharge visit at WCIMA, 37.2 % (N=188/506) had the visit within 30 days of hospital discharge, and 37.7 % (N=190/506) saw their assigned PCP. In WCIMA patients discharged from the ED/Urgent care, 35.8 % (N=375/1,047) had a post discharge visit at WCIMA, 24.1 % (N=242/1,047) had the visit within 30 days of discharge, and 19.2 % (N=201/1,047) saw their PCP. The mean follow up interval was 23.01 days (SD 22.360) after a Medicine discharge and 25.40 days (SD 23.619) after ED/Urgent care. The mean age of all discharged patients was 52.62 years (SD 18.468). Patients who completed post-discharge appointments were significantly older than those who did not (57.2 vs. 49.3 years, $P<0.001$), however, this difference was lost when examining Medicine patients alone.

CONCLUSIONS: Only half of WCIMA patients discharged from Medicine during the study period, and fewer from the ED/Urgent care had a WCIMA follow up visit, indicating significant missed opportunities to coordinate care from hospital to home. Fewer than half had visits within 30 days or saw their assigned PCP. Overall, older patients were more likely to follow up. Other resident teaching practices likely have similar challenges in hospital-outpatient continuity. We have designed an intervention using a transitions registrar and care manager to ensure timely and appropriate post discharge care. We hope the intervention will identify one strategy to improve follow up rates and clinical outcomes among patients of a large internal medicine teaching clinic.

FOOD INSECURITY AND COST-RELATED MEDICATION UNDERUSE ARE INDEPENDENT BARRIERS TO DIABETES CONTROL: RESULTS FROM THE MEASURING ECONOMIC INSECURITY IN DIABETES (MEND) STUDY Seth A. Berkowitz¹; James B. Meigs¹; Steven J. Atlas¹; Darren A. DeWalt⁴; Hilary K. Seligman³; Deborah J. Wexler². ¹MGH, Boston, MA; ²MGH, Boston, MA; ³UCSF, San Francisco, CA; ⁴UNC, Chapel Hill, NC. (Tracking ID #1934690)

BACKGROUND: Food insecurity, cost-related medication underuse (CRMU), and housing instability may be significant, yet modifiable, barriers to diabetes management. However, whether these barriers are independently associated with poor diabetes control, accounting for other aspects of low socioeconomic status and comorbidity, is unclear. To inform future population management interventions, we tested the hypothesis that they are independently associated with poor diabetes control.

METHODS: We contacted a stratified random sample of adult (age >20 years) diabetes patients in 4 clinic sites (2 community health centers, 1 academic internal medicine practice, and a diabetes center) from June 15–Sept 15th 2013. Participants completed validated instruments assessing food insecurity, CRMU, and housing instability, in English or Spanish. We also collected information on other social circumstances, including educational attainment, limited English proficiency (LEP), health literacy, and nativity, along with age, gender, race/ethnicity, insurance, diabetes duration, Charlson comorbidity score, diabetes medications, Hemoglobin A1c (HbA1c) tests/year and number of outpatient visits. The primary outcome was poor diabetes control (most recent HbA1c >9.0 % or LDL cholesterol >100 mg/dL). We estimated prevalence using inverse probability weighting. We performed multivariable logistic regression analysis with generalized estimating equations to account for clustering by clinic, and used pseudo-R² statistics to evaluate explained variation in diabetes control.

RESULTS: Overall, 412 patients were included (response rate: 62 %). Of these, 19 % reported food insecurity, 28 % CRMU, and 11 % housing instability. Patients reporting food insecurity were more likely to be younger (mean age 56 vs. 63 years, $p=.01$), non-white (35 % vs 22 %, $p=.01$), and have Medicaid (22 % vs. 11 %, $p=.03$). In unadjusted analyses, the prevalence of poor diabetes control was higher in those with, vs. without, food insecurity (53 % vs. 28 %, $p=.01$), CRMU (53 % vs. 22 %, $p=.01$) and housing instability (56 % vs. 30 %, $p=.01$). Those with, vs. without, food insecurity, CRMU, or housing instability had similar comorbidity and HbA1c tests/year (an indicator of engagement with care), but more outpatient visits/year (Table 1). In a multivariable regression analysis, adjusted for the covariates listed above, food insecurity and CRMU were associated with worse diabetes control (Table 2). Using Pseudo-R² statistics, our model explained 28 % of the variation in diabetes control; food insecurity, CRMU, and housing accounted for 4 % of total variation. By comparison, education, health literacy, LEP, and nativity (other indicators of social disadvantage) together explained only 2 %.

CONCLUSIONS: Food insecurity and CRMU are common, and independently identify patients at increased risk of poor diabetes control despite similar comorbidity and engagement with care. Because these patients already have higher healthcare utilization, interventions targeting food insecurity and cost-related medication underuse may have greater utility than increasing usual care.

Table 1

	Food Insecure	Food Secure	<i>p</i> -value	Cost-related Medication Underuse	No Cost-related Medication Underuse	<i>p</i> -value	Unstable Housing	Stable Housing	<i>p</i> -value
Charlson Score Median (IQR)	4 (3–7)	4 (2–7)	.44	4 (3–6.5)	4 (2–7)	.84	3.5 (2–6)	4 (3–7)	.11

FOOD INSECURITY IS ASSOCIATED WITH DIABETES SELF-CARE BEHAVIORS AND GLYCEMIC CONTROL William J. Heerman¹; Ken Wallston²; Chandra Y. Osborn³; David Schlundt⁴; Shari D. Barto¹; Russell L. Rothman¹. ¹Vanderbilt University Medical Center, Nashville, TN; ²Vanderbilt University Medical Center, Nashville, TN; ³Vanderbilt University Medical Center, Nashville, TN; ⁴Vanderbilt University, Nashville, TN. (*Tracking ID #1928444*)

BACKGROUND: Food insecurity is the “limited or uncertain availability of nutritionally adequate and safe foods,” and has been associated with worse glycemic control among patients with type 2 diabetes (T2DM). Less is known about food insecurity’s relationship with diabetes self-care behaviors, and whether its effects on glycemic control can be attributed to that relationship. Therefore, we examined the relationships between food insecurity, self-care, and glycemic control, and whether any effect on glycemic control was due to relationships with self-care.

METHODS: We conducted a cross-sectional analysis of baseline data from patients with T2DM enrolled in a randomized trial evaluating a health literacy-focused diabetes intervention at 10 county health departments across middle Tennessee. Food insecurity was assessed with 3 items from the U.S. Household Food Security Survey and patients who answered “sometimes” or “often” to at least one of these items were considered “food insecure.” Diabetes self-care behaviors were assessed with the Summary of Diabetes Self Care Activities Scale (SDSCA), Personal Diabetes Questionnaire (PDQ-11), and Adherence to Refills and Medication Scale (ARMS). Glycemic control was assessed with A1C, collected prospectively unless available in medical record within 4 weeks of study enrollment. Student’s t-tests or Wilcoxon rank-sum tests were used to evaluate the bivariate relationships between food insecurity and each self-care behavior, food insecurity and A1C, and each self-care behavior and A1C. Significant bivariate relationships were re-examined using linear regression models adjusted for gender, ethnicity, education, and income. Mediational analyses were performed as appropriate.

RESULTS: The sample consisted of 401 participants, of whom 61 % were female, 57 % self-identified as non-Hispanic White, 17 % as non-Hispanic Black, 24 % as Hispanic, and 2 % as non-Hispanic other. The majority (88 %) were uninsured, and 37 % had less than a high school education. Nearly three-quarters (73 %) reported some level of food insecurity. Food insecurity was significantly associated with self-care behaviors (Table) including less adherence to a general diet ($p=0.03$), routine physical activity ($p=0.05$), and medications ($p=0.01$), and a greater occurrence of poor eating ($p=0.02$) and skipping meals ($p=0.03$). Food insecurity was also associated with worse glycemic control (adjusted β co-efficient 0.6, $p=0.015$). The median A1C for food insecure participants was 9.8 % (IQR 8.2, 11) compared to 9.3 % for food secure participants (IQR 7.7, 10.6). There was no relationship between any of the self-care behaviors assessed and A1C, so tests for mediation were not performed.

CONCLUSIONS: There was a high rate of food insecurity in this sample of diabetes patients with low socioeconomic status. Food insecurity was associated with less adherence to recommended self-care behaviors, a greater occurrence of undesirable behaviors, and worse glycemic control. Further work is needed to understand the mechanisms by which food insecurity impacts self-care, including behaviors not directly related to food (e.g., physical activity and medication adherence) as well as the mechanisms by which it also impacts glycemic control. While our measures of self-care were not associated with A1C, limiting our ability to explore self-care as a mechanism, other more sensitive measures of behavior may hold promise. Nonetheless, our findings contribute to a limited literature on the relationship between food insecurity and diabetes behaviors.

Food Insecurity and Diabetes Self-Care Behaviors

	All Participants (n=401)	Food Secure (n=109)	Food Insecure (n=292)	P- value

FOOD INSECURITY, COPING STRATEGIES, AND GLYCEMIC CONTROL IN LOW-INCOME PATIENTS WITH DIABETES Victoria L. Mayer¹; Kevin H. McDonough¹; Hilary K. Seligman²; Judith A. Long^{1,3}. ¹Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; ²University of California San Francisco, San Francisco, CA; ³Philadelphia Veterans Affairs Medical Center, Philadelphia, PA. (*Tracking ID #1933037*)

BACKGROUND: In the U.S., people who are food insecure (lack sufficient food for an active and healthy life) have a higher prevalence of diabetes and worse diabetes control. However, the mechanisms underlying these associations are not well understood. In this study we evaluate the relationship between food insecurity and coping strategies hypothesized to worsen glucose control in a population of low-income diabetics.

METHODS: We performed a cross-sectional telephone survey among low-income adults with diabetes seen at a large, urban medical center. We interviewed people within 8 weeks of having a hemoglobin A1c (HbA1c) evaluation and characterized individuals as having poor glycemic control ($\text{HbA1c} \geq 8.0$) or adequate glycemic control ($\text{HbA1c} < 8.0$). The main independent variable was a dichotomous measure of food insecurity (18-item U.S. Department of Agriculture Household Food Security Survey Module). We assessed the use of coping strategies including a diet low in fruits and vegetables and high in added sugars (using the California Health Interview Survey Dietary Screener), foregone medications, foregone medical care, use of food assistance programs (including the Supplemental Nutrition Assistance Program - SNAP) and emergency food programs, and overeating in times of adequacy. Additional independent variables included socio-demographic and clinical covariates. In bivariate analyses, we compared glucose control and use of coping strategies in the food insecure and food secure groups. We developed logistic regression models to evaluate the association between food insecurity and glucose control, with adjustment for covariates and coping strategies. Finally, we assessed the role of interactions between food insecurity and coping strategies.

RESULTS: Of 413 respondents (response rate 51 %), 40.4 % were food insecure. The food insecure group had a higher proportion of patients with poor glycemic control (68.3 % vs. 53.3 %, $p=0.002$). There were no significant differences between the food insecure and food secure groups in daily intake of fruits, vegetables, or added sugars. A significantly higher percentage of patients in the food insecure group reported foregone medications, foregone medical care, participation in food assistance programs and use of emergency food programs. Food insecure patients were also more likely to report overeating at times when food is adequate. However, these coping strategies were not significantly associated with glucose control. In the adjusted model without interaction terms, when compared to food secure individuals,

food insecure individuals were more likely to have poor glucose control (OR 2.83, 95 % CI 1.47–5.44). However, there was a significant interaction between food insecurity and receipt of SNAP: food insecure individuals receiving SNAP benefits were less likely to have poor glucose control (OR 0.28, 95 % CI 0.09–0.90), while food insecure individuals not receiving SNAP were more likely to have poor glucose control (OR 7.41, 95 % CI 2.41–22.77).

CONCLUSIONS: Food insecurity was associated with higher risk of poor glucose control. While more prevalent among patients who were food insecure, many coping strategies previously thought to underlie this relationship were not significantly associated with poor glucose control. However, receipt of food assistance among food insecure individuals was associated with better diabetes control, suggesting that in addition to helping individuals afford food, such programs may also play a role in improving health.

FORGET ME NOT: A RANDOMIZED TRIAL OF THE DURABILITY OF HOSPITAL-BASED EDUCATION ON INHALERS FOR PATIENTS WITH COPD OR ASTHMA Valerie G. Press¹; Vineet Arora²; Kristin L. Constantine³; Edward T. Naureckas⁴; Steven R. White⁴; Jerry Krishnan⁵. ¹University of Chicago, Chicago, IL; ²University of Chicago, Chicago, IL; ³University of Michigan, Ann Arbor, MI; ⁴University of Chicago, Chicago, IL; ⁵University of Illinois at Chicago, Chicago, IL. (*Tracking ID #1934140*)

BACKGROUND: As part of a nationwide strategy to reduce readmissions for chronic diseases, hospitals are increasingly using the inpatient setting as a “teachable moment” to train patients in important self-management techniques to improve both patient-centered outcomes as well as to avoid preventable re-hospitalizations. Inpatient education is particularly salient for patients with COPD, which is the 3rd leading cause of readmission among Medicare patients, who are often not aware how to use their preventive and rescue inhaler medications correctly. While hospital-based education is not new, it is unclear how durable it is and when reinforcement may be needed. The objective of this two-center randomized clinical trial was to test the short-term effectiveness and longer-term retention of a guideline-based, patient-centered approach, called teach-to-goal (TTG) compared to a brief intervention (BI) of simple verbal instructions to teach inhaler technique to inpatients with COPD or asthma.

METHODS: Patients were randomized to TTG or BI, stratified by level of health literacy (high/low/unknown [due to insufficient vision]). Use of metered-dose inhaler (MDI) and Diskus® devices was assessed using step-by-step checklists. Misuse was defined as <75 % of steps correct. TTG participants received cycles of inhaler demonstration followed by re-assessment of technique (“teach-back”). BI participants received verbal instructions without demonstration. Participants returned at 30-days and 3 months post-hospital discharge. Significance was tested using Chi square and Fishers exact tests.

RESULTS: Between September 2011–October 2012, 120 participants were enrolled from two urban hospitals and were randomized to either the TTG ($n=62$) or BI ($n=58$) interventions. The majority were female (73 %) and African-American (90 %), with a mean age of 47 years. Two-thirds (66 %) had been hospitalized at least once in the last year and nearly half (49 %) had a near-fatal event (ICU admission and/or intubation) in their lifetime. Fifteen percent had insufficient vision, 19 % had low health literacy. Eighty-nine percent of participants returned at 30-days and 86 % returned at 3 months. There were no baseline differences between groups (TTG vs. BI) in the baseline prevalence of misuse for either MDI or Diskus. Immediately after education, misuse was less common in TTG vs. BI for MDI (11 vs. 60 %, $p<0.001$) and Diskus devices (5 vs. 61 %, $p=0.001$). At 30-days there were no significant differences in misuse for either MDI (53 vs. 70 %, $p=0.09$) or Diskus (53 vs. 59 %, $p=0.73$). Despite the lack of significant 30-day findings, MDI misuse was significantly less likely at 3 months in the TTG vs. BI group (48 vs. 76 %, $p=0.003$). A similar result at 3 months for the Diskus device was not seen ($p=0.2$). Stratifying the results by level of health literacy did not produce any clear patterns [Table]. There were no differences between TTG and BI for any health literacy group at 30 days; those with adequate health literacy were less-likely to misuse MDI at 3 months in TTG vs. BI group ($p=0.02$). Participants were less-likely to misuse Diskus if they received TTG vs. BI for those with adequate health literacy ($p=0.006$) or less-than-adequate health literacy ($p=0.048$), but not for those with insufficient vision ($p>0.99$). There were no differences between TTG and BI for any health literacy group at 30-days or 3 months for the Diskus device.

CONCLUSIONS: Although patient-centered TTG education can improve self-management skills among inpatients with asthma or COPD, the effects of hospital-based education wane over time. This suggests that in order to improve patient-reported outcomes and potentially decrease re-admissions, post-discharge educational reinforcement is likely necessary for long-term mastery of chronic disease self-

management. Further, data are needed about the effectiveness of hospital-based education on subsequent clinical outcomes for hospitalized patients with COPD or asthma in the short-term and long-term after hospital discharge.

Proportion of Misuse

	MDI		<i>p</i> -value	DISKUS		<i>p</i> -value
	TTG	BI		TTG	BI	
Baseline	92	84	n/a	75	89	n/a
Post-education	11	60	<0.001	5	61	<0.001
30-days	54	70	0.112	53	59	0.73
3 months	48	76	0.003	38	63	0.157

TTG: Teach To Goal; BI: Brief Intervention

FROM FLIPPING THE CLASSROOM TO FLIPPING THE HOMEWORK: A LEARNER-CENTERED APPROACH TO ADVANCE PREPARATION ASSIGNMENTS Paul Haideit; Klara Papp; Daniel R. Wolpaw. Penn State College of Medicine, Hershey, PA. (*Tracking ID #1939412*)

BACKGROUND: The commonly used convention for preparing learners to participate in active classroom learning is to assign them pre-readings or similar materials. We have found that such published resources do not always align well with educational objectives. Further, pre-reading assignments often present information according to the teacher's organizational schema, rather than allowing students to identify learning needs and incorporate material according to their own emerging conceptual frameworks. We sought to develop a method for advance preparation that addresses these issues.

METHODS: We designed a 2-hour session on “introduction to educational concepts” for junior faculty enrolled in a 12-month faculty development fellowship. The in-class portion used the Team-Based Learning method to foster active learner participation. However, rather than assign specific readings for the pre-session preparation, we gave learners a list of 27 educational terms (e.g., ‘Bloom’s Taxonomy’, etc.) and instructed them to research unfamiliar terms and reflect on their own assumptions and beliefs regarding teaching. We performed internet searches using the terms to review information that our learners might access. We distributed a post-session survey containing three open-ended questions that addressed how the assignment: 1) affected learning about educational concepts, 2) differed from typical reading assignments, and 3) influenced levels of enjoyment during completion. We performed a thematic analysis of learner responses to the open-ended questions.

RESULTS: Nineteen learners (33 % women) participated in the session and returned surveys (100 % response). Forty-eight percent of learners were clinically focused in their scholarly work, 28 % educationally focused, and 24 % research focused. For our session, several themes emerged from the responses about the advance preparation assignment. First, some learners struggled with uncertainty and a need to find the “right” answer, particularly when they found conflicting information. A few learners viewed uncertainty as an opportunity to deepen understanding, because it forced them to critically appraise information, identifying knowledge gaps during the process. Second, learners generally perceived more active engagement as compared to typical reading assignments; however, this effect was tempered for learners who focused on collecting definitions at the expense of understanding concepts. Finally, the majority of learners expressed enjoyment with the assignment and appreciated the ability to allocate preparation time according to their own needs.

CONCLUSIONS: Using a learner-directed approach for advance preparation merits further exploration. Learner experiences suggested more active, critical thinking, and may represent more efficient and deeper learning of course concepts, and better preparation for subsequent learning in the classroom. Future work should more rigorously test these outcomes, and explore additional methods of fostering learner-centeredness in advance preparation assignments.

FULFILLING UNMET NEEDS: INTEGRATING WOMEN’S HEALTH INTO THE INTERNAL MEDICINE RESIDENCY PROGRAM CURRICULUM Sneha Shrivastava; Abby Spencer. Allegheny General Hospital, Pittsburgh, PA. (*Tracking ID #1941879*)

BACKGROUND: National guidelines and the American Board of Internal Medicine (ABIM) have highlighted key areas of women’s health that are critical to the training of an internal medicine resident. The federated council for Internal Medicine (FCIM), who sets the core knowledge curriculum for IM residency programs, argues that all general internists should be competent in conditions that are “unique to, more common in or more serious in women or that have manifestations, risk factors, or interventions that are different in women”. Our objective is to improve the women’s

health curriculum in a large academic community Internal Medicine residency program.

METHODS: A 147-item anonymous online survey was sent to PGY1&2 residents to assess their comfort, perceived knowledge, perceived importance, and exposure to 28 Women's Health topics identified as critical to the training of an internist. Topics were selected based on a thorough literature review, curricular recommendations by ABIM, FCIM, and the NIH Women's Health Congress. We used descriptive statistics to determine and rank comfort, exposure, perceived knowledge, and perceived importance of the topics. We then analyzed the In-Training exam results from the last 3 years and compared the performance of our residents to national data on topics related to women's health. Based on our survey results and ITE review, we designed a new longitudinal interactive women's health curriculum to meet critical learning needs of our residents. Curricular methods included problem-based learning (PBL) workshops on osteoporosis, multi-disciplinary case conferences on depression and anxiety during pregnancy traditional didactics, and STD jeopardy. Our interprofessional panel experts during case conferences included faculty from internal medicine, psychiatry, and obstetrics-gynecology Pre-post surveys were conducted after problem-based learning (PBL) and multi-disciplinary case conferences. The Wilcoxon signed-rank test was used to compare resident knowledge and comfort before and after case conferences.

RESULTS: Response rate on the initial survey was 63 % (38/60). Non-responders were similar to responders in gender and pgy-year. 13/28 topics were identified as having the highest perceived importance to our IM residents. Of these, residents felt they had insufficient clinical exposure in prescribing contraception, evaluating breast symptoms, managing menopause, performing pap smears and pelvic exams, and diagnosing or managing polycystic ovarian syndrome (PCOS). Lower clinical exposure in these areas correlated significantly with lower comfort and lower perceived knowledge. Osteoporosis was identified by residents as their single greatest learning need; this topic was rated as highly important and residents had low knowledge and comfort with it. While residents reported a low perceived knowledge on several women's health topics, their performance on the In-Service exam was on par with that of the national average. After an interactive PBL conference on osteoporosis, 95.1 % of the residents felt knowledgeable and comfortable in this topic as compared to 37.9 % who were knowledgeable and comfortable before the case discussion ($p=0.0003$). After the multi-disciplinary case discussion on anxiety and depression during pregnancy, 80.1 % of the residents felt more comfortable in this topic as compared to only 36.4 % who were comfortable before the case discussion ($p=0.0009$). Additionally, 94.7 % of the residents preferred PBL conference and 88.9 % of the residents preferred multi-disciplinary conference to a standard noon conference lecture. All the residents (100 %) agreed that PBL cases and multi-disciplinary conferences are extremely effective methods of learning.

CONCLUSIONS: Our study highlighted significant gaps in our women's health curriculum. Additionally, there is a concerning perception among residents that many topics critical to the health of women and the education of IM residents are not very important. Based on our findings, we are redesigning our didactic and experiential women's health curriculum to augment knowledge, comfort, importance of, and exposure to areas in need. Problem based learning and multi-disciplinary case discussions are effective educational tools to achieve this. Enhancing education and increasing clinical exposure to fundamental women's health issues will produce better residents and promote higher quality care for women.

GENDER AND RACIAL DIFFERENCES IN CONTROL OF CARDIOVASCULAR DISEASE RISK FACTORS AMONG VETERANS Karen M. Goldstein^{1,3}; S. Dee Melnyk^{1,4}; Leah L. Zullig^{1,5}; Karen Stechuchak¹; Eugene Z. Oddone^{1,3}; Lori A. Bastian^{6,7}; Susan Rakley^{2,3}; Maren Olsen^{1,8}; Hayden Bosworth^{1,9}. ¹Durham Veterans Affairs Medical Center, Durham, NC; ²Durham Veterans Affairs Medical Center, Durham, NC; ³Duke University, Durham, NC; ⁴University of North Carolina, Chapel Hill, NC; ⁵University of North Carolina, Chapel Hill, NC; ⁶University of Connecticut Health Center, Farmington, CT; ⁷VA Connecticut Healthcare System, West Haven, CT; ⁸Duke University, Durham, NC; ⁹Duke University, Durham, NC. (Tracking ID #1934589)

BACKGROUND: Female Veterans are the fastest growing Veterans Administration (VA) patient population, nearly doubling in the past decade. Compared with non-Veteran females, Veteran women have higher rates of cardiovascular disease (CVD) risk factors, such as smoking and obesity, which put them at significant risk for long-term cardiovascular morbidity and mortality. Recent findings suggest that black female Veterans are more likely to have a diagnosis of hypertension, diabetes, and obesity compared with white female Veterans. However, there is little information about CVD risk factor control between male and female Veterans, particularly by race. We sought to address the following: 1) Is there a significant difference in CVD risk factor control between men and women Veterans at high risk for CVD, defined as poor control of blood pressure (mmHg), hemoglobin A1c, and LDL cholesterol (mg/dL); and 2) Is there a significant difference in CVD risk factor control between African-American and White Veterans by gender, defined as blood pressure (mmHg), hemoglobin A1c, and LDL cholesterol (mg/dL)?

METHODS: We used analysis of variance, adjusting for age, to compare gender and racial differences in three risk factors that predispose to CVD (i.e. diabetes, hypertension, and hyperlipidemia) in a cohort of Veterans who were eligible for enrollment in a clinical trial. To be eligible for the trial, individuals had to be enrolled at the Durham VA Medical Center and have a diagnosis of hypertension, hyperlipidemia, or both. Means provided were estimated from our ANOVA model that adjusted for age. Our sample included 23,955 men (33.9 % black and 54.0 % white) and 1,010 women (54.8 % black and 39.3 % white).

RESULTS: LDL values were higher in female than male Veterans with hyperlipidemia with age-adjusted estimated mean values of 111.7 mg/dl vs 97.6 mg/dl ($p<0.01$). There was no difference in LDL values between black and white women. There was a small but significant difference between black and white male Veterans with hyperlipidemia, specifically 99.6 mg/dl vs 95.8 mg/dl respectively ($p<0.01$). Systolic blood pressures were similar between male and female Veterans with hypertension, though there was a significant difference in diastolic blood pressures of 79.0 mmHg vs 76.8 mmHg ($p<0.01$) respectively. Blood pressures were higher among black than white female Veterans with hypertension with age-adjusted estimated mean systolic blood pressures of 136.3 mmHg versus 133.5 mmHg, respectively ($p<0.01$), and diastolic blood pressures of 82.4 mmHg versus 78.9 mmHg ($p<0.01$); a similar pattern between black and white male Veterans was also seen. There was no difference in hemoglobin A1c between male and female Veterans with diabetes. Age-adjusted estimated mean hemoglobin A1cs for African-American and White men were 7.5 and 7.3 ($p<0.01$), respectively. Age-adjusted estimated mean hemoglobin A1cs for African-American and White women were 7.6 and 7.1 respectively, though this was not significant.

CONCLUSIONS: Among this Veteran population at high-risk for CVD, we found that female Veterans had worse control of hyperlipidemia than male Veterans. This difference was observed despite the fact that female Veterans in this cohort on average were almost 10 years younger than male Veterans. In addition, we found that African-American women and men had worse blood pressure control than white women. Further examination of CVD gender and racial disparities in this population may help to develop targeted treatments and strategies applicable to the general population.

GENERAL MEDICINE CAREER INTEREST, PRIMARY CARE KNOWLEDGE AND MENTORSHIP AFTER PARTICIPATING IN A STUDENT-FACULTY COLLABORATIVE PRACTICE Charlotte E. Ward; Emma C. Jeffries; Marya J. Cohen. MGH, Boston, MA. (Tracking ID #1938150)

BACKGROUND: It is becoming increasingly difficult for patients to find primary care physicians (PCPs) in the United States. The Medicaid expansion will extend coverage to 30 million new patients, many of whom will likely need a PCP. It is important therefore, to attract a greater number of medical students to the field of primary care and to better understand factors that contribute to student career interests. The Crimson Care Collaborative (CCC), a series of five student-faculty collaborative practices, aims to give students hands-on practical experience in understanding innovation in primary care clinics across the Harvard Medical School network. We surveyed medical students before and after participating in CCC. Our goal was to examine whether knowledge and understanding of primary care-related constructs, and interest in general medicine as a career, increased after participating in CCC. A secondary aim was to examine whether influential factors, such as mentorship and peer and faculty support for primary care, also increased over time.

METHODS: All Harvard Medical School (HMS) students who joined CCC as student-volunteers and participated for a minimum of one semester were administered pre- and post-participation surveys. The surveys focused on assessing career interest, attitudes toward and knowledge about primary care, and presence of faculty mentoring. Pre- and post-survey responses were compared using logistic regression.

RESULTS: The study population included 225 HMS students who filled out a survey prior to participating in CCC and 61 HMS students who filled out a post-survey; 31 students completed both a pre- and post-survey. Students who completed a post-survey were more likely to report having interest in or having decided upon a career in general medicine compared to students who completed a pre-survey (Pre: 38.9 %, Post: 59 %, $p=0.01$). Post-survey respondents were more likely to report feeling comfortable with their knowledge of chronic disease management (Pre: 24.9 %, Post: 52.5 %, $p<0.001$), understanding the role of coordination of care (Pre: 55.6 %, Post: 73 %, $p=0.01$), and understanding the roles of non-MD clinicians on patient care team (Pre: 49.3 %, Post: 73.8 %, $p=0.03$) compared with students who completed a pre-survey. Students who completed a post-survey were more likely to report having heard positive comments about primary care from residents (Pre: 11.8 %, Post: 23 %, $p=0.04$), students (Pre: 33.5 %, Post: 36.1 %, $p=0.65$) and faculty (Pre: 31.1 %, Post: 34.4 %, $p=0.58$) compared to pre-survey respondents. Post-survey respondents were also more likely to agree with the positive comments that they heard about primary care compared to pre-survey respondents (Pre: 84.1 %, Post: 93.3 %, $p=0.07$). Finally, post-survey respondents were more likely to report knowing an HMS faculty member whose career in general medicine is one they would like to emulate (Pre: 37.2 %, Post: 50.8 %, $p=0.14$).

CONCLUSIONS: For a group of medical students who participated in a primary-care based student-faculty collaborative clinic, rates of knowledge and interest in general medicine increased. Factors that would be influential in student interest and knowledge, such as mentorship and peer support, also increased from pre- to post-survey administration. Further research is needed in order to assess what factors predict general medicine or primary care career interest.

GRAND-PARENTING EXPERIENCES AMONG ADULTS WITH A HISTORY OF DEPRESSION: A MIXED-METHODS STUDY Adriana Izquierdo¹; Jeanne Miranda¹; Elizabeth Bromley^{1,2}; Cathy Sherbourne³; Gery Ryan³; David Kennedy³; Kenneth B. Wells¹. ¹University of California Los Angeles, Los Angeles, CA; ²West Los Angeles VA Healthcare Center, Desert Pacific Mental Illness Research, Education, and Clinical Center (MIRECC), Los Angeles, CA; ³RAND, Santa Monica, CA. (*Tracking ID #1923290*)

BACKGROUND: Grand-parenting is an important social role but how adults with a history of depression experience grand-parenting is unknown; we describe grand-parenting experiences reported by an ethnically-diverse sample of adults with a history of depression. **METHODS:** Mixed-methods study using semi-structured interviews of adults at 10-year follow-up and quantitative data collected over 9 years from 280 systematically-sampled participants from a longitudinal, multi-site trial of quality-improvement interventions for depressed primary care patients; of 280, 110 reported noncustodial grand-parenting experiences.

RESULTS: Of 110 adults reporting grand-parenting experiences, 90 (82 %) reported any positive experience such as special joy; 57 (52 %) reported any stressful experience such as geographic separation; 27 (34 %) reported mixed experiences. Adults with chronic or recent depression were significantly more likely than their respective counterparts to report any stressful experience ($p<0.05$). There was no significant association between depression status and reporting a positive experience.

CONCLUSIONS: Grand-parenting was a highly salient and positive experience as reported by ethnically-diverse adults 10 years after being identified as depressed in primary care. Depression status was associated with reporting stressful but not positive experiences. Specific themes underlying positive and stressful experiences may have implications for developing strategies to enhance quality of life for adults with a history of depression who are grandparents.

GRASSROOTS REFORM OF DISCHARGE SUMMARIES - ASSESSING HOUSE STAFF ATTITUDES Madeline R. Sterling¹; Mallory Otto¹; Brian Eiss²; Eugenia Siegler². ¹New York Presbyterian - Weill Cornell, New York, NY; ²New York Presbyterian - Weill Cornell, New York, NY. (*Tracking ID #1927328*)

BACKGROUND: With more transitions of care in the era of hospitalist-based medicine, a greater focus must be placed on handoffs to preserve patient safety. Discharge summaries (dsumms) are a prime example. Research has identified many flaws with current dsumms; outpatient practitioners are dissatisfied with the quality of dsumms, and medication reconciliation errors made in dsumms lead to readmission. However little is known about the attitudes of the primary authors of these documents at academic institutions, namely interns, residents, and physician assistants (PAs). This study aims to address this gap.

METHODS: Surveys were administered to 79 of 135 residents (PGY 1–3) and 10 PAs at a large academic medical center in New York City. The survey was developed using resident focus groups and was internally validated via review by an expert committee. Using Likert scale analysis, dichotomous relationships, and open-ended questions, the survey sought to measure the attitudes of residents and PAs (house staff) toward authoring dsumms. Surveys were voluntarily completed and anonymous. Results were calculated and stratified by level of training or PA. Comparisons of interns (PGY1) vs. residents (PGY2 and PGY3) and of MDs (PGY1, PGY2, and PGY3) vs. PAs were also conducted for relevant questions and assessed using Fishers exact test. This study was approved by the institutional review board.

RESULTS: Of 89 respondents, 38 (42.7 %), 21 (23.6 %), 20 (22.5 %), and 10 (11.2 %) were PGY1, PGY2, PGY3, and PAs, respectively. Eighty-four percent reported to authoring and using dsumms frequently, and 77.2 % reported that quality dsumms are useful for primary care practitioners. Compared to upper level residents however, interns have less experience in using the discharge summary in the outpatient setting (23.7 % vs. 63.4 %, $P<0.001$). Interns were also less comfortable authoring dsumms for patients who were not their primary responsibility, compared to their resident colleagues (47.4 % vs. 24.4 %, $P=0.038$). While over three-quarters of housestaff reported having received formal teaching at least once on authoring dsumms, 54.8 % of interns surveyed reported never receiving feedback from their senior resident or attending on their dsumms, and no PAs reported ever received feedback from attendings. Furthermore, the majority of interns and 90 % of PAs responded that further formal teaching would be helpful.

CONCLUSIONS: This study demonstrates a gap in translating theory into practice. While greater than three-quarters of house staff identified the importance of a dsumm in the transfer

of care, interns especially admit that they are not comfortable authoring discharge summaries for patients they may not have cared for during the duration of their hospital stay, a rather common practice for MDs on rotational schedules. Furthermore, they welcome further teaching. The interns' discomfort in authoring dsumms for patients they do not know well likely speaks to their lack of experience in general, and thus targeted teaching sessions and/or feedback, especially from their residents who report more comfort in this arena, may be most appropriate at this level. Future studies could further characterize the effect formalized feedback and/or teaching sessions have on house staff attitudes toward dsumms.

GRATEFUL PATIENT PHILANTHROPY: A QUALITATIVE STUDY OF PATIENTS WHO GIVE BACK TO THEIR DOCTORS Sean Tackett¹; Rosalyn W. Stewart²; Leah Wolfe¹; Scott Wright¹. ¹Johns Hopkins Bayview Medical Center, Baltimore, MD; ²Johns Hopkins Hospital, Baltimore, MD. (*Tracking ID #1935909*)

BACKGROUND: Philanthropy is a vital source of financial support for academic medical centers, and grateful patients are the single most important source for substantive philanthropic gifts. The factors surrounding patients' decisions to make financial donations have not been empirically studied.

METHODS: Individual structured interviews were conducted with 20 patients who were identified by the Johns Hopkins Medicine development office as having made significant financial contributions to Johns Hopkins Medicine. An interview guide was developed to elicit patients' initial motivations for giving, how patients became aware of the need for financial support, how their gifts may have affected their care or relationships with treating physicians, and the elements of stewardship that were most effective. Interviews were transcribed verbatim. Content analysis was performed by two investigators using an editing analysis style.

RESULTS: Informants were on average 65.1 years old (range 45–87 years) and had affiliations with Johns Hopkins Medicine for a mean of 22.3 years (range 3–64 years). Most (13/20, 65 %) were men. Estimated personal financial donations ranged from a few thousand dollars to over \$15 million (median \$500,000), and most (11/20, 55 %) also supported the institution in other ways (e.g. serving on a board). Their donations were directed in various ways, including unrestricted gifts to individual physicians, support for specific research projects that relate to illnesses of interest (e.g. those affecting donors themselves or donors' loved ones), endowed chairs, and institutional gifts directed to new construction. While some donations were made after the first clinical encounter, others came after decades of exposure to Johns Hopkins physicians. Five themes emerged from the analysis that shed light on this content area: (i) excellence in patient care was an activating provocation that stimulated patients to consider making donations, (ii) patients welcomed learning about, and were comfortable discussing, specific ways in which they could direct donations, (iii) gifts were often intended to support the work and effort of physicians whom patients had come to respect and admire, (iv) patients felt satisfied knowing their gift could make things better for future patients, and (v) stewardship and explanations about how gifts were being used further encouraged and activated donors. Additionally, while most patients sensed that they now receive "VIP" treatment, they maintained that they did not expect special treatment as a result of their gifts. Similarly, none felt that their gift impacted the doctor-patient component of their relationship, and none believed that there were ethical issues associated with their giving.

CONCLUSIONS: This study of patients that have made philanthropic contributions to our institution suggests that the best way to attract significant donations is to make exceptional patient care routine. Patients with significant means who are grateful for the care they have received appreciate knowing how they can contribute and feel gratified from giving back.

GUYS GET PAP TESTS TOO: DEVELOPING CERVICAL CANCER SCREENING PATIENT OUTREACH MATERIALS FOR FEMALE-TO-MALE TRANSGENDER PATIENTS Ida M. Bernstein^{1,2}; Sarah M. Peitzmeier³; Sari L. Reisner^{2,4}; Jennifer Potter^{1,5}. ¹Harvard Medical School, Boston, MA; ²Fenway Health, Boston, MA; ³Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ⁴Harvard School of Public Health, Boston, MA; ⁵Beth Israel Deaconess Medical Center, Boston, MA. (*Tracking ID #1938176*)

BACKGROUND: The American College of Obstetricians and Gynecologists recommends that female-to-male (FTM) transgender patients with a cervix follow the same cervical cancer screening guidelines as non-transgender women. However, there are unique barriers to screening for transgender men, including a disconnect between biological sex and gender identity, a high frequency of trauma histories, and a high likelihood of being nulliparous, among others. We have found that even at Fenway Health, an urban health clinic with expertise working with lesbian, gay, bisexual and transgender (LGBT) populations, FTM patients are significantly less likely to be up-to-date on Pap tests and 10 times more likely to have an inadequate Pap than non-transgender women (in press). Targeted interventions are needed to improve Pap utilization among FTM patients, including improved patient outreach materials. This study seeks to develop novel community-driven cervical cancer screening outreach materials for FTM patients.

METHODS: In-depth interviews (IDI) and an open-ended online survey administered on LimeSurvey® software were conducted with individuals who were 21 or older, born with a cervix, and self-identified on the FTM spectrum. Participants were purposively recruited through advertisements on social media, the Fenway Health website, and local trans community listservs. Topics explored in the IDIs and survey included participant experiences with Pap tests and preferences for a patient outreach campaign. Text and images of a brochure on cervical cancer screening for FTM patient outreach were developed from qualitative analysis of interview transcripts and survey responses. Existing community-driven cervical cancer screening education materials were reviewed and compared to participant feedback. A team of clinicians, patient outreach and transgender healthcare specialists reviewed and edited the brochure.

RESULTS: We performed 32 IDIs (Mean age 33.3 (SD=10.6), 18.8 % racial/ethnic minority) and received 65 completed online survey responses (Mean age 33.4 (SD=8.98), 13.8 % racial/ethnic minority). Some of the key themes identified from participant feedback and incorporated in designing the brochure text include: (1) FTM patients and their providers should jointly customize the Pap test to fit varying patient needs and comfort levels; (2) a need for gender-neutral language and presentation of Pap tests and associated health information; and (3) feeling in control during the exam and having confidence in provider competency in trans care are priorities for many trans men. Participant feedback informing the selection of images for the brochure included a desire for representation of diversity in age, gender expression, and race/ethnicity of the FTM community as well as exclusion of images of women, medical equipment, and anatomical diagrams.

CONCLUSIONS: The experiences with Pap tests and preferences regarding patient outreach materials reported in this study reflect the unique barriers to adequate cervical cancer screening faced by the trans masculine community. However, the diversity of acceptability of and comfort with Pap tests that was observed across participants suggests that presenting options for customization of the exam and strategies to increase comfort and control during screening may be an effective outreach tool. A brochure was developed from participant feedback that will be further evaluated by community member focus groups to ensure it is effectively tailored to the needs of FTM individuals.

HAS CARDIOVASCULAR DIAGNOSTIC TESTING BECOME THE SIXTH 'VITAL SIGN' IN THE EMERGENCY DEPARTMENT? NHAMCS 2009–2010

Anil N. Makam; Oanh K. Nguyen. University of Texas Southwestern Medical Center, Dallas, TX. (Tracking ID #1939616)

BACKGROUND: Current cardiology guidelines are increasingly discouraging cardiovascular diagnostic testing among low-risk ambulatory populations. Routine use of electrocardiograms (ECGs) on hospital admission has also been long discouraged due to low diagnostic utility. However, little is known about the extent of cardiovascular testing among low-risk populations in acute care settings such as the emergency department (ED). We hypothesize there is a high prevalence of cardiovascular diagnostic testing even among individuals who present to the ED without risk factors, signs or symptoms of cardiovascular disease.

METHODS: We analyzed data from the 2009–2010 National Hospital Ambulatory Medical Care Surveys (NHAMCS), a probability sample of ED visits in the US. Our primary outcome was the collection of cardiovascular tests (ECG and/or cardiac enzymes) during ED visits in adults (≥ 18 years) who were subsequently hospitalized. We estimated the adjusted probabilities of cardiovascular testing in the ED in low risk, average risk, and high risk scenarios using multivariate logistic regression adjusting for patient, visit and ED characteristics.

RESULTS: This study included 8,089 visits, representing 15.1 million ED visits per year by adult patients who were subsequently hospitalized. Of these visits, 52 % (95 % CI, 50 %–54 %) had symptoms potentially attributable to cardiovascular disease, and 59 % (95 % CI, 56 %–61 %) had a cardiovascular admitting diagnosis. Overall, 69 % of individuals (95 % CI, 66 %–71 %) had cardiovascular diagnostic testing, with 59 % (95 % CI, 57 %–62 %) having an ECG and 47 % (95 % CI, 43 %–51 %) with cardiac enzymes collected. In a low-risk scenario (25th percentile for age = 44 years, female, no cardiovascular symptoms, normal vital signs, no comorbidities, no cardiovascular admission diagnosis, disposition to a non-ICU bed, no/mild pain, normal mental status, non-emergent triage, and 0–5 other tests or services performed), 21 % (95 % CI, 18 %–25 %) of individuals had cardiovascular diagnostic testing (Table). In an average risk scenario (50th percentile for age = 59 years and holding all other covariates at their mean values), 72 % (95 % CI, 69 %–74 %) had cardiovascular diagnostic testing. In a high-risk scenario (75th percentile of age = 76 years, male, cardiovascular symptom(s) present, abnormal vital sign(s), 2–4 comorbidities, cardiovascular admission diagnosis present, disposition to an ICU bed, moderate/severe pain, abnormal mental status, emergent triage, and >10 other tests or services performed), 99 % (95 % CI, 99 %–100 %) had cardiovascular diagnostic testing.

CONCLUSIONS: There is excessive cardiovascular diagnostic testing among low-risk individuals and highly prevalent testing among average-risk individuals in the emergency department. Our findings suggest more attention is needed to develop strategies for more targeted use of cardiovascular diagnostic tests among individuals presenting to the ED for care.

Table: Adjusted Probability of Cardiovascular Testing in the ED Among Subsequently Hospitalized Individuals^a

^b Defined by 'reason for visit' fields.

^c Abnormal vital signs defined as ≥ 1 of the following: heart rate ≥ 100 or <60 beats/min, systolic blood pressure ≥ 160 or <90 mmHg, diastolic blood pressure

≥ 100 or <60 mmHg, respiratory rate <10 or >20 breaths/min, or oxygen saturation <90 %.

^d Diabetes, CHF, cerebrovascular disease, or ESRD on dialysis.

^e ≥ 1 'ED provider diagnosis' fields coded as a disease of the circulatory system per the AHRQ Clinical Classification Software.

HEALTH ACCESS INDICATORS AND ER USE AMONG LATINO MEDICAID BENEFICIARIES Hugo A. Torres¹; Ed Yelin². ¹Cambridge Health Alliance, Cambridge, MA; ²University of California, San Francisco, San Francisco, CA. (*Tracking ID #1939978*)

BACKGROUND: The Medicaid program is a major source of health insurance for the Latino population. The purpose of this study is twofold: first, to measure the association between health access indicators and insurance type in the Latino population, comparing Medicaid to private insurance. The second is to assess chronic disease care by measuring differences in ER and hospital usage for ambulatory-care-sensitive conditions (ACSC) between Medicaid and privately-insured Latinos.

METHODS: This is a cross-sectional study utilizing the 2009 California Health Interview Survey (CHIS). The population studied is Latino respondents, aged 18–64, with private or Medicaid insurance (N=5005). The principal independent variable is health coverage. For the first objective, the outcome is presence of a usual source of care (USOC) and interruption in health insurance in the past year. For the second objective, the analysis was limited to patients with conditions that have been documented to be ambulatory-care sensitive (ACSC); the outcome variable is ED visit or hospitalization for an ACSC. We use logistic regression to control for age; gender; rural location; education; English-speaking ability; presence of children; and self-reported health, chronic disease, and disability status.

RESULTS: There were 5,005 survey respondents that met the inclusion criteria, of whom 28.4 % were Medicaid recipients. Medicaid recipients were more likely to be female, younger, Spanish-speaking, and have children in the household. Medicaid recipients also had a lower level of education and mean income than the privately-insured respondents of the survey. Significantly more Medicaid recipients reported fair/poor health status (68.8 % vs. 52.5 %), and disability due to a physical or emotional condition (31.2 % vs. 21.0 %). 67.0 % of Medicaid recipients reported having a USOC, compared to 85.5 % of privately-insured patients (OR 0.34, $p < 0.0001$). The proportion of Medicaid recipients who were uninsured at any time in the past year is 25.6 %, compared to 6.5 % of privately-insured people (OR 2.9, $p = 0.002$). After adjustment with logistic regression, Medicaid recipients were half as likely to report having a USOC (OR=0.52, 95%CI 0.37–0.73, $p < 0.0001$) and three times more likely to report having been uninsured in the past year (OR 3.0, 95%CI 2.0–4.5, $p < 0.0001$). Among patients with chronic disease, there was a trend toward more Medicaid respondents reporting use of the emergency department or being hospitalized in the past year: 13.0 % of Medicaid recipients used the ER in the past year for their chronic condition, compared to 6.8 % of privately-insured patients, (OR=2.04, $p = 0.082$). This association became statistically significant after adjustment for the covariates (OR=2.2, $p = 0.03$).

CONCLUSIONS: This study demonstrates that Latinos with Medicaid report worse health access and have a greater chance of going to the emergency room with a chronic condition than those with private insurance, even when controlled for demographic variables and health status. In light of the importance of having a usual source of care and continuous insurance in the prevention of adverse health outcomes, these findings point to a need to ensure that a robust primary care system and education on how to access it support Medicaid patients. This is particularly true of patients with chronic disease, where strong primary care supports can prevent unnecessary emergency room visits or hospital stays.

HEALTH AND FINANCIAL HARM OF 25 STATES' DECISION TO OPT OUT OF MEDICAID EXPANSION David Himmelstein²; Samuel L. Dickman¹; Danny McCormick^{1,3}; Steffie Woolhandler². ¹Harvard Medical School, Boston, MA; ²City University of New York, School of Public Health, New York, NY; ³Cambridge Health Alliance, Cambridge, MA. (*Tracking ID #1929214*)

BACKGROUND: As of December 2013, 25 states have chosen to opt out of expanding Medicaid coverage for low-income adults following the Supreme Court ruling that they are not required to do so. Salutary effects of previous Medicaid expansions have been observed in several states. We quantified the health and financial consequences of states' decision to opt out.

METHODS: We categorized states as opting in or opting out of Medicaid expansion using data from the Kaiser Family Foundation. We used data from the 2013 Current Population Survey to project the number of persons in each state who will remain uninsured after implementation of the Affordable Care Act (ACA) and to analyze the number of people whose health and financial circumstances would improve if states opting out of Medicaid expansion were to opt in. We used data from the Oregon Health Insurance Experiment to predict the effects of Medicaid expansion on cervical and breast cancer screening, pharmacotherapy for diabetes mellitus, catastrophic medical expenditures and positive depression screening. We used two prior studies of

the impact of insurance on death rates (Wilper et al., 2009 and Sommers et al., 2012) to project excess mortality associated with opt-outs.

RESULTS: Of the 47.95 million people who were uninsured in 2012, 32.20 million will remain so after implementation of the ACA, 7.78 million of whom would have been covered had all states expanded Medicaid. Medicaid expansion in opt-out states would have resulted in between 7,115 and 17,104 fewer deaths, 712,037 fewer persons screening positive for depression, 240,700 fewer persons suffering catastrophic medical expenditures, 422,533 more diabetics receiving medication, 195,492 more indicated mammograms and 443,677 additional indicated pap smears.

CONCLUSIONS: Many low-income adults will forego health and financial benefits that would be expected had their states opted to expand Medicaid coverage.

HEALTH INSURANCE PLAN KNOWLEDGE IN MASSACHUSETTS: A COMPARISON OF CONSUMERS OBTAINING INSURANCE FROM A HEALTH EXCHANGE, NON-EXCHANGE SOURCE OR MEDICAID Rachel Nardin^{1,3}; Leah Zallman^{1,2}; Assaad Sayah^{1,3}; Danny McCormick^{1,3}. ¹Cambridge Health Alliance, Cambridge, MA; ²Institute for Community Health, Cambridge, MA; ³Harvard Medical School, Cambridge, MA. (*Tracking ID #1935010*)

BACKGROUND: Like the Affordable Care Act, the 2006 Massachusetts health care reform law (fully implemented by 2008) expanded Medicaid coverage and created a state health insurance exchange offering publicly subsidized private health insurance plans (called Commonwealth Care (CWC)) to low income residents. Informed decision-making by those seeking insurance coverage requires that the application process, as well as the cost and coverage features of plans, be comprehensible. Limited understanding of plan features could adversely affect utilization of care and could undermine the consumer-driven competition between plans that is expected to be a key driver of health plan affordability. However, little is known about health plan knowledge among those obtaining Medicaid or a subsidized health plan via a health insurance exchange.

METHODS: Between August and December 2013, we conducted face-to-face structured interviews with a convenience sample of 681 patients presenting to three emergency departments at a large safety net health care system in the Boston area. We confirmed respondents' insurance type using a statewide database updated daily. We included patients age 18–64 who had only one type of insurance and spoke English, Portuguese, Spanish or Haitian Creole. We excluded severely ill patients. We examined subjects' responses to questions about the application process for their current insurance, about their knowledge of their current plan's costs and benefits and about whether the extent of their knowledge affected their utilization of care. Comparisons across insurance types were made using the chi-square test.

RESULTS: Of the 681 participants, 16 % were uninsured, 14 % had CWC, 42 % had Medicaid and 28 % had private insurance. Overall, 21 % of respondents reported not understanding features of their coverage, including costs, and 34 % reported not being confident in their knowledge; this did not vary by insurance type. Among those who were not confident, 33 % delayed medical care due to this uncertainty. Overall, 24 % of respondents found it difficult to apply for their current insurance; this was significantly worse for those with publicly subsidized than for those with private insurance (Medicaid 25 %, CWC 35 %, private 14 %, $p = 0.03$). Similarly, more respondents reported difficulty completing the application process for Medicaid (39 %) and CWC (37 %) than for private insurance (16 %, $p = 0.003$). Overall, 41 % of respondents said the information provided regarding plan choices was hard to understand, 17 % said they did not have all the information they needed about costs when signing up for a plan and 38 % reported difficulty submitting the paperwork necessary to keep their insurance active; these measures did not vary by insurance type.

CONCLUSIONS: A high proportion of safety-net patients in Massachusetts report knowledge deficits about their insurance plan features and the application process, often resulting in delayed medical care due to this uncertainty. Those obtaining Medicaid and subsidized insurance through the state exchange reported the greatest difficulties. New federal and state insurance exchanges created under the Affordable Care Act should provide information about health plans and the application process in a format that is readily understandable to consumers. Relying on informed consumer choice to maximize competition in insurance exchanges may be premature.

HEALTH LITERACY AND USABILITY OF PATIENT EDUCATION DOCUMENTS Raman Singhal¹; Katya Ostrow²; Calie Santana¹. ¹Montefiore Medical Center, Bronx, NY; ²Sackler School of Medicine, Tel Aviv, Israel. (*Tracking ID #1929654*)

BACKGROUND: In 2003, the National Assessment of Adult Literacy found that 36 % of the population has basic or below basic health literacy and 41 % of Bronx

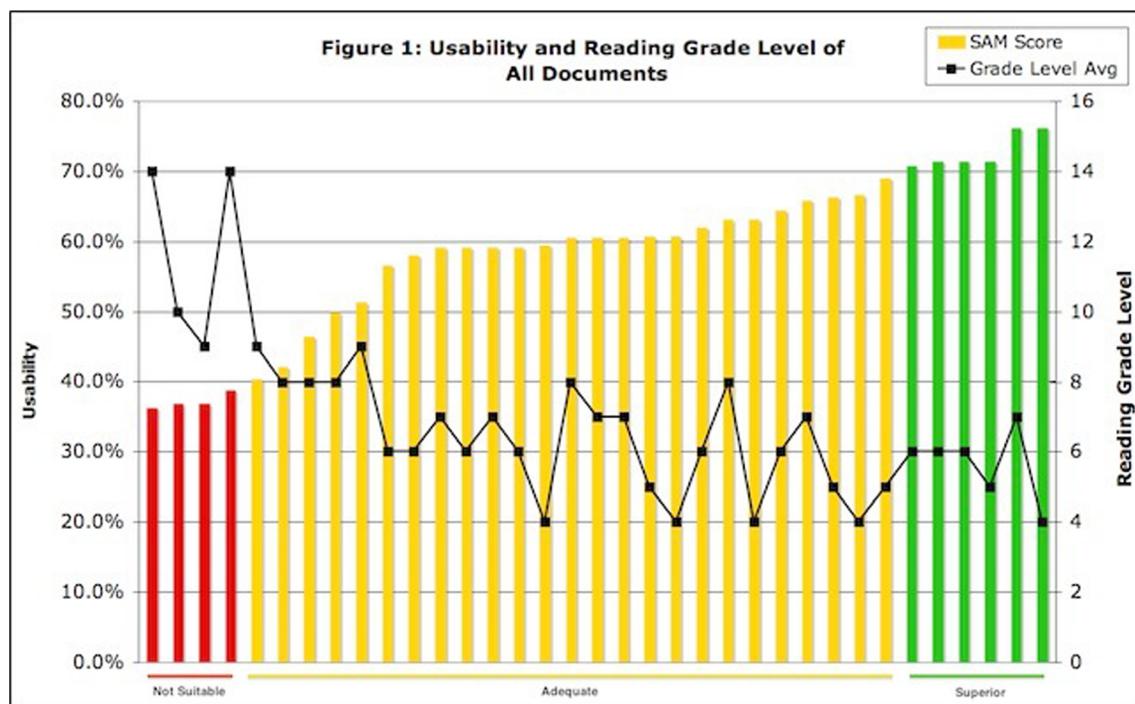

County adults lack basic literacy skills. With the advent of electronic medical records (EMRs), the dissemination of patient education materials has become increasingly feasible and required as part of the meaningful use federal incentive program. It remains largely unknown, however, if patients can understand and act on the information presented. We sought to determine the literacy level and usability of patient handouts, which document characteristics should be improved upon to increase usability, and how documents from different vendors perform on a usability scale.

METHODS: We analyzed 35 patient education documents in English from four vendors (A–D) and pertaining to six medical conditions (3 acute, 3 chronic) using the Suitability Assessment of Materials (SAM) tool. Vendors A and D provide easy-to-read (“basic”) as well as regular (“standard”) versions of documents—we analyzed 11 basic and 9 standard documents. The SAM tool assesses a document’s usability in six domains: content, literacy demand, graphics, layout/typography, learning stimulation, and cultural appropriateness. The literacy demand domain incorporates the reading grade level of the document’s text, which was calculated manually. Documents were printed in black-and-white, and were randomly numbered. Two researchers (RS and KO), blinded to each other’s scores and vendor, reviewed each document. For each document, we calculated a usability score, defined as the average SAM score—usability is categorized as not suitable (SAM<40 %), adequate (40–70 %), or superior (>70 %). We also calculated the average score for each domain; because of the disparate weighting of each domain within the SAM score, domain scores were converted to percentages.

RESULTS: Usability ranged from 36.3 to 76.2 %—25 documents (71 %) were adequate, six were superior, and four were not suitable. Figure 1 shows this distribution and the relationship between usability and reading grade level. All not-

suitable documents were written at or above the 9th grade reading level and all superior documents were written between the 4th and 7th grade level. The 11 basic documents had an average reading grade level of 5.7 (range 4–7), 1 (9 %) had superior usability, and zero were not suitable. The 9 standard documents averaged a 9.3 reading grade level (range 6–14), zero had superior usability, and 3 (33 %) were not suitable. As expected, average scores in all domains of the SAM tool trended up with increasing usability; the highest correlation was with literacy demand and the lowest with layout/typography. By domains, literacy demand achieved the highest average score across all documents at 75.3 %, while graphics achieved the lowest at 30.7 %. Documents from vendor A had an average usability score of 56.4 %, vendor B 70.3 %, vendor C 61.9 %, and vendor D 52.9 %. Vendors A (25 %) and D (75 %) produced all not-suitable documents, and vendor B produced 66 % of the superior documents.

CONCLUSIONS: The majority of patient education handouts available to us are acceptable by health literacy standards. Literacy demand had the highest correlation with usability, however, our study highlights that it is just one factor in creating a superior document. As an example, the literacy differences between basic and standard documents are muted when these documents are scored for usability. While several documents have mastered the literacy domain, the next area to improve is graphics—this domain had the second highest correlation with usability, but the lowest average score. As we aim to always choose usable documents, our results show that vendor B produced a majority of the superior documents. B’s documents achieved the highest average score in 4 domains, excelling by the greatest absolute magnitude in the graphics domain. As we increase the use of printed materials in our daily practice, we must continue to critically appraise their value and quality to ensure that they are useful for our patients.

HEALTHCARE FRAGMENTATION IN A MAJOR U.S. CITY Lisa M. Kern¹, Zachary Grinspan¹; Jason Shapiro²; Rainu Kaushal¹. ¹Weill Cornell Medical College, New York, NY; ²Mount Sinai School of Medicine, New York, NY. (*Tracking ID #1939540*)

BACKGROUND: American healthcare is fragmented, with patients routinely seeking care from multiple providers in different practices and health systems. Healthcare fragmentation is thought to be particularly common in cities with multiple academic medical centers. Healthcare fragmentation is important, because it can lead to fragmentation of clinical information (that is, clinical information that is needed by healthcare providers but which is missing at the point of care because of gaps in communication across providers). Previous studies have estimated that such gaps

occur frequently, with relevant clinical information missing in one of every seven ambulatory visits, potentially contributing to adverse events and readmissions. The degree to which healthcare fragmentation is contributing to this problem of information fragmentation has not been measured. In the absence of data on the amount of healthcare fragmentation, healthcare providers and policy makers may underestimate the actual degree of fragmentation and may, thus, underestimate the value of interventions designed to address it. Our aim was to derive a quantitative estimate of the amount of healthcare fragmentation in New York City.

METHODS: We conducted a longitudinal study using data from 2010 to 2011. We obtained the data from a health information exchange (HIE) organization previously called the New York Clinical Information Exchange (NYCLIX); it subsequently merged with another HIE organization and is now part of Healthix. We selected data

from NYCLIX because it had detailed information on individual patient encounters with health care. The NYCLIX data included emergency department (ED) and inpatient visits for patients who sought care at six hospitals in Manhattan: Beth Israel Medical Center, Mount Sinai Medical Center, New York-Presbyterian Hospital, New York University Medical Center, Roosevelt Hospital, and St. Luke's Hospital. For each patient who sought ED or inpatient care at one of the six hospitals, we determined whether that patient had been seen in a different hospital in the previous 12 months. This analysis allowed the specific 12-month window to vary from patient to patient, fixing time zero as the date of that patient's encounter in 2011. The purpose of this analysis was to calculate the rate of encounters for which a patient's clinical information could be missing if data were not exchanged across providers.

RESULTS: We identified 566,907 patients who were seen in the ED or inpatient settings in the six participating hospitals in 2011. We found that each of the six hospitals shared patients with every other hospital. For the entire group of patients, we found that there were 74,196 ED visits for which clinical information could have been missing, because the patient had been seen elsewhere in the previous 12 months. This is equivalent to 10.0 % of ED visits having potentially missing clinical information. Similarly, we found that there were 31,967 inpatient admissions for which clinical information could have been missing, because the patient had been seen elsewhere in the previous 12 months. This is equivalent to 9.1 % of inpatient admissions having potentially missing clinical information. The risk of potentially missing clinical data varied slightly by institution, but all institutions were affected. Depending on the institution, between 6.8 % and 16.9 % of ED visits had clinical data potentially missing. Similarly, between 6.6 % and 26.5 % of inpatient admissions had clinical data potentially missing, depending on the institution.

CONCLUSIONS: Healthcare fragmentation in New York City is extensive. All six participating hospitals were affected by healthcare fragmentation, with each hospital having its patients seen at each of the other five hospitals in a single year. It was very common for patients to seek care at the ED or inpatient setting of one hospital and have had previous care within the past 12 months at another hospital; this affected 10 % of all ED visits and 9 % of all inpatient admissions. This puts both patients and hospitals in a risky situation, in which relevant clinical information may be missing at the point of care. Interventions designed to decrease healthcare fragmentation are needed. In addition, interventions such as electronic health information exchange are needed, as they can potentially facilitate the efficient sharing of clinical data across providers and minimize the impact of healthcare fragmentation.

HEALTHCARE PROFESSIONALS' ATTITUDES, PERCEPTIONS AND PRACTICES REGARDING BREAST SELF-EXAMINATION Kah Poh Loh¹; Eng Keong Tan¹; Owolabi Ogunneye¹; Jennifer Friderici¹; Reva Kleppel¹; Mihaela S. Stefan¹; James Stewart². ¹Baystate Medical Center/Tufts University, Springfield, MA; ²Baystate Medical Center/Tufts University, Springfield, MA. (*Tracking ID #1934250*)

BACKGROUND: In 2009, the United States Preventive Service Task Force (USPSTF) published a revised guideline for breast cancer screening. Specifically for breast self-examination (BSE), USPSTF recommends against teaching breast self-examination, as opposed to the previous guideline stating "insufficient evidence to suggest for or against BSE". The objectives of this study is to assess healthcare professionals' knowledge, perception and attitude in BSE as well as their adherence to the newly revised USPSTF guideline in BSE. We hypothesized that the knowledge and adherence of healthcare providers to the USPSTF newly revised guidelines is poor.

METHODS: A cross-sectional survey study was carried out in five medical and gynecological practices affiliated with a large academic teaching hospital in Western Massachusetts. The survey was populated and e-mailed to all attendings, residents, advanced practitioners (APs), physician assistants (PAs) and nurses working in these medical practices. The first part of the survey contains demographic data including gender, age, residency program, job position, previous experience in medical practice in years and medical school they graduated from. The second part of the survey will enquire their awareness and perceptions of the 2009 USPSTF guidelines in BSE and clinical breast examination by physician, followed by their practices in BSE and the reasons why they do or do not teach BSE and whether any of their patients detected any breast lumps through BSE. Characteristics associated with adherence and knowledge were compared using Fisher's Exact test and univariable logistic regression analysis. Characteristics associated with adherence and knowledge were compared using Fisher's Exact test and univariable logistic regression analysis.

RESULTS: The survey completion rate was 50.7 % (104/205). Respondents were primarily female (64.4 %, a median (IQR) age of 31 years (29, 43)). Fifty-one percent of the responders were residents, 26.0 % were attending MDs and 23.1 % were APs, PAs and nurses. Fewer than half of respondents correctly perceived the 2009 USPSTF guidelines for BSE (41.4 %, 95 % CI 31.7 %, 51.0 %). Most (70.2 %, 95 % CI

61.3 %, 79.1 %) teach patients to perform BSE. The most frequent reason cited for teaching BSE was "early detection of cancer (48.0 %), and to "empower woman", (37.0 %). In univariable analyses, recommendation for BSE was significantly associated with female gender (OR 2.64, 95 % CI 1.11, 6.29). Other characteristics which showed an association without reaching statistical significance were: ≥5 years of practice (OR 2.11, 95 % CI 0.84, 5.30); non physician practitioner (OR 3.5, 95 % CI 0.82, 14.93); US Med School (OR 2.20, 95 % CI 0.84, 5.75); ever detecting a lump in a patient (OR 2.95, 95 % CI 0.80, 10.87) and belief that BSE reduces morbidity and mortality (OR 2.12, 95 % CI 0.84, 5.37). Among 35 respondents who stated they were aware of USPSTF guidelines, surprisingly approximately half (48.6 %) taught BSE frequently or occasionally.

CONCLUSIONS: Knowledge of, and adherence to, the 2009 USPSTF guidelines related to BSE is relatively low. Several personal and professional characteristics may be associated with adherence. Despite being aware of the guidelines, some health professionals still taught BSE. Greater efforts should be made to educate healthcare professionals about the 2009 USPSTF guidelines.

HEALTHCARE PROVIDERS' KNOWLEDGE OF DIFFERENT DIETS AND DIETARY ADVICE PROVIDED TO PATIENTS Sonali Arora^{1,2}; Auras R. Atreya²; Reva Kleppel²; Jennifer Friderici³; Tara Lagu²; Michael B. Rothberg⁴.

¹Baystate Medical Center/Tufts University School of Medicine, Springfield, MA; ²Baystate Medical Center/ Tufts University School of Medicine, Springfield, MA;

³Baystate Medical Center, Springfield, MA; ⁴Cleveland Clinic, Cleveland, OH. (*Tracking ID #1938959*)

BACKGROUND: Therapeutic lifestyle changes, including diet and exercise, are considered first line therapy for patients at risk of coronary heart disease (CHD). It is unknown what dietary advice healthcare providers offer to patients and whether they tailor that advice to specific risk factors. Similarly, healthcare providers' knowledge of the evidence supporting various diets has not been assessed. Our objective was to determine which diets physicians recommended to patients, as well as their beliefs about the evidence behind those recommendations.

METHODS: We surveyed attending physicians, fellows, residents, nurse practitioners and physician assistants in internal medicine, cardiology, endocrinology and family medicine at multiple practices within Baystate Health, a large integrated health system in Western Massachusetts. The 22-question survey was devised by the investigators to determine physicians' dietary recommendations for patients with diabetes mellitus (DM), hypertension (HTN), dyslipidemia, obesity and CHD; and to test healthcare providers' knowledge regarding published evidence for various diet recommendations. Knowledge scores were constructed based on number of correct responses to questions about evidence for the benefits of various diets. Average knowledge scores were compared according to provider characteristics using one-way analysis of variance.

RESULTS: The overall response rate was 57 % (115/203); and 13 questionnaires were excluded from the knowledge calculation for incomplete knowledge scores. Among 102 remaining responses, 40 (39 %) were attending physicians, 46 (45 %) house staff and 16 (16 %) advanced practitioners. The majority (*n*=88, 86 %) were from primary care specialties and 76 (75 %) worked in an academic practice. Seventy-nine percent (79 %) of healthcare providers felt it was important for patients to follow a healthy diet, but only 27 % offered dietary advice to all patients. Instead, 66 % gave dietary advice to high-risk patients or those who asked for advice. The top dietary recommendation for HTN was a low salt diet (79 %), for uncontrolled DM a low carbohydrate diet (65 %), for obesity a low calorie diet (75 %), for CHD and for dyslipidemia a low saturated fat diet (64 % and 74 % respectively). Only 9 % of healthcare providers recommended the same diet for all conditions. Providers believed that their 58 % of their incorrect diet recommendations were supported by randomized trial evidence. The most common misconceptions were that randomized trial evidence existed that low carbohydrate diet helps control DM (58 % of providers) and that Mediterranean diet increases life expectancy (51 % of providers). Respondents' overall knowledge of randomized trial evidence for dietary interventions was low (Mean/SD knowledge score 32 %/13 %, range 0 % to 58 %). Knowledge scores of attending physicians were significantly higher than those of house staff (+6.0 percentage points, *p*=0.02) and advanced practitioners (+11.0 percentage points, *p*=0.006). Knowledge scores did not vary significantly between specialties (32 % primary care vs. 30 % other, *p*=0.72) or practice type (30 % academic practice vs. 35 % non-academic, *p*=0.10).

CONCLUSIONS: Physicians and advanced practitioners report recommending different diets depending on specific risk factors and generally believe that their recommendations are evidence based. However, there remain substantial gaps between their knowledge and the randomized trial evidence regarding diet in disease prevention. Apart from increased provider education regarding diets (through medical school curricula, residency training and CME), guidelines

could take a more comprehensive approach to cardiovascular risk reduction, rather than focusing on single specific macronutrients for individual risk factors.

HIGH VALUE CARE BY US INTERNAL MEDICINE RESIDENTS: USING EXAM VIGNETTES TO ASSESS PRACTICE Kira L. Ryskina^{1,2}; Deborah Korenstein³; Arlene Weissman³; Philip Masters³; Patrick C. Alguire³; Cynthia D. Smith³. ¹University of Pennsylvania, Philadelphia, PA; ²University of Pennsylvania, Philadelphia, PA; ³American College of Physicians, Philadelphia, PA. (*Tracking ID #1940181*)

BACKGROUND: Unsustainably high healthcare spending in the US has lead to calls to incorporate high value care (that balances benefits of tests or treatments against potential harms and costs) as a competency for internal medicine residents. However, objective evaluation of resident practice of high value care (HVC) is a challenge for educators. In this study, we describe the development of an assessment of HVC resident practice using a set of clinical vignettes from the Internal Medicine In-Training Examination (IM-ITE).

METHODS: HVC concepts were broadly discussed with IM-ITE authors prior to and during question development. After the exam was finalized, three physicians independently reviewed each of the 340 questions for selection in the HVC subscore and categorized each selected question according to six specific HVC rationales. We measured inter-observer agreement across reviewers for (1) question selection, and (2) the HVC rationale, using Fleiss' kappa statistic. Exam questions were included in the HVC subscore if, after discussion, the reviewers reached a consensus about both the item and the associated rationale. The IM-ITE exam from which the HVC subscore was defined was administered in October 2012. Using descriptive statistics, we characterized residents' HVC subscore performance according to their year of training, medical school location, residency program track, career plans, overall ITE performance, and the Dartmouth Atlas' hospital care intensity (HCI) index of the training hospital. We used multivariate linear regression with clustering at the program level to identify resident and program characteristics associated with hypothetical practice of HVC, adjusting for overall exam performance and other potential confounders.

RESULTS: Thirty-eight questions were included in the HVC subscore. Initial inter-observer agreement was moderate for question selection ($\kappa=0.56$, 95 % CI 0.51–0.58, $p<0.001$), and fair for HVC rationale ($\kappa=0.25$, 95 % CI 0.16–0.26, $p<0.001$). Of the 18,102 US residents who completed the exam and had a measurable subscore, 34.1 % were PGY1, 34.6 % were PGY2, and 31.3 % were PGY3. About one in five (20.3 %) planned to pursue a career in general internal medicine. The mean HCI index of participants' hospitals was slightly higher than the national average (1.12 vs. 1.0, $p<0.001$). The average percent correct was lower for the HVC subscore compared to the overall exam (60.1 % vs. 63.1 %, $p<0.001$). The HVC subscore correlated strongly with the overall exam score (Pearson correlation coefficient 0.73, $p<0.001$). The mean HVC subscore was lower for interns compared to senior residents (20.1 vs. 24.0, $p<0.001$) and slightly higher for residents who trained at a hospital with below average HCI index compared to those who trained at a hospital with above average HCI index (22.6 vs 22.0, $p<0.001$). The difference in mean HVC subscores between residents trained at high vs. low HCI index hospitals was more pronounced for residents in lower quintiles of overall exam performance (Table). After adjusting for resident and program characteristics and overall test performance, the HVC subscore was negatively associated with the HCI index of the training hospital (beta coefficient -0.31 , $p=0.02$, 95 % CI -0.57 – -0.05).

CONCLUSIONS: The process used to develop an HVC subscore of the IM-ITE exam had face validity and resident scores varied slightly based on their home institution's level of healthcare utilization. Although alone it is likely inadequate, this measure may assist in evaluation of resident practice of HVC and may also motivate program directors and residents to focus their learning and curriculum more on high value care principles.

Mean Subscore by Quintile of HCI and Overall Performance

Quintile of overall performance	Mean Subscore for Lowest HCI Index Quintile (SD)	Mean Subscore for Highest HCI Index Quintile (SD)	P-value
Lowest	18.5 (4.0)	17.5 (3.9)	<0.0001
2nd	20.9 (3.7)	20.2 (3.8)	0.0005
Middle	22.7 (3.7)	22.0 (3.6)	0.0002
3rd	24.2 (3.5)	23.8 (3.4)	0.047
Highest	26.6 (3.5)	26.3 (3.2)	0.15

HOME-BASED PRIMARY CARE IS ASSOCIATED WITH REDUCED AMBULATORY CARE SENSITIVE HOSPITALIZATIONS IN VETERANS WITH DIABETES Samuel T. Edwards^{1,2}; Julia Prentice^{3,4}; Steven R. Simon^{1,5}; Steven D. Pizer^{3,6}. ¹VA Boston Healthcare System, Boston, MA; ²Harvard Medical School, Boston, MA; ³VA Boston Healthcare System, Boston, MA; ⁴Boston University, Boston, MA; ⁵Brigham and Women's Hospital, Boston, MA; ⁶Northeastern University, Boston, MA. (*Tracking ID #1927327*)

BACKGROUND: Intensive primary care and home-based services have the potential to reduce the likelihood of hospitalization of elderly patients with multiple chronic diseases. We examined the relationship between enrollment in Home Based Primary Care (HBPC), a national home care program operated by the US Department of Veterans Affairs (VA) and ambulatory care sensitive condition (ACSC) hospitalizations among elderly Veterans with diabetes.

METHODS: We performed a national cohort study of Veterans over age 67, who were traditional Medicare beneficiaries, had a diagnosis of diabetes mellitus and one other chronic disease, and had at least one hospitalization in 2005 or 2006. Our primary exposure was enrollment in HBPC, defined as a minimum of 3 HBPC encounters. Our main outcome was hospitalization due to an ambulatory care sensitive condition, as measured by the Agency for Healthcare Research and Quality Prevention Quality Indicators. Our data consisted of VA records supplemented by Medicare claims. Patients were followed from January 1st 2006 or 2007 (end of baseline year) through December 31st, 2010. Outcomes were analyzed using a two-stage discrete time survival model with distance from the Veteran's residence to a VA facility that provides HBPC serving as an instrumental variable to control for selection. Patients were censored after enrollment in Medicare Advantage or death.

RESULTS: We identified a total of 56,502 Veterans with a total of 2,049,838 person-months of follow up for analysis. Of these patients, 1,872 enrolled in HBPC and 54,630 did not. HBPC patients were older (mean 79.1 years vs. 77.1 years), and more often black (20.8 % black among HBPC patients vs. 10.9 % black among non-HBPC patients). HBPC patients had higher diabetes severity (Young's Diabetes Severity Index mean 4.8 vs. 4.2), and had more co-existing conditions such as CHF (59.2 % vs. 53.5 %). HBPC patients also had a higher prevalence of mental illness including psychosis (24.6 % vs. 13.7 %) and depression (32.6 vs. 18.3 %). Multivariate predictors for HBPC enrollment included paralysis (OR 2.12, 95 % CI 1.63–2.76), depression (OR 2.03, 95 % CI 1.73–2.40), CHF (OR 1.37, 95 % CI 1.17–1.59) and distance from HBPC providing VA (10–30 miles vs. <5 miles, OR 0.58, 95 % CI 0.49–0.70). After controlling for selection, HBPC enrollment was associated with a 22.5 % relative reduction in the probability of experiencing one or more ACSC hospitalizations in one year (table), corresponding to an absolute reduction in risk of ACSC hospitalization of 7 %, from 27 to 20 %.

CONCLUSIONS: HBPC enrollment is associated with decreased risk of ACSC hospitalization among elderly Veterans with diabetes. Programs like HBPC may play an important role in the management of elderly patients with multiple chronic diseases in accountable care models.

Change in probability of one or more ACSC hospitalization in 1 year associated with HBPC and other comorbidites

	Relative change in probability	p
HBPC	-22.5 %	<0.01
CHF	42.4 %	<0.01
COPD	36.0 %	<0.01
Pulmonary Circulatory Disorder	15.9 %	<0.01
Fluid/Electrolyte Imbalance	12.6 %	<0.01
Depression	10.8 %	<0.01
Diabetes Severity Index (per unit)	2.6 %	<0.01

HOSPITAL TO HOME HEALTH CARE TRANSITIONS: A GAP ANALYSIS OF TARGETS FOR QUALITY IMPROVEMENT Christine D. Jones¹; Julie E. Clemons¹; Ethan U. Cumbler¹; Benjamin Honigman²; Darren A. DeWalt⁴; Eric A. Coleman³; Robert Burke⁵; Heidi Wald^{1,3}. ¹University of Colorado School of Medicine, Aurora, CO; ²University of Colorado School of Medicine, Aurora, CO; ³University of Colorado School of Medicine, Aurora, CO; ⁴University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁵Department of Veterans Affairs Medical Center, Eastern Colorado Health Care System, Denver, CO. (*Tracking ID #1933651*)

BACKGROUND: Adequate information exchange is critical to high-quality care transitions, yet little is known about the quality of information transfer from hospitals to home health care services. To evaluate perceptions of completeness and timeliness

of medical information transferred from a tertiary care University Hospital to home health care agencies, we performed a cross-sectional survey of home health care clinicians and staff.

METHODS: During the fall of 2013, we submitted a web-based 34-question survey to 30 individuals from two health agencies that provide the highest volume post-hospitalization home health care for the hospital's discharged patients. The survey explored various aspects of care coordination, including access to medical records in a timely fashion and adequacy of information provided. Respondents could select answers from a 4- or 5-point Likert scale as well as enter free-text comments.

RESULTS: 24 of 30 home health representatives responded to the survey (80 % response rate). Among 24 respondents, 46 % identified as client services managers, 38 % were clinical managers, and 17 % held other positions (e.g., administration, liaison, marketing, etc.). We found that 38 % of respondents indicated having "occasional" or "rare" access to sufficient information from the hospital about a patient's discharge medical conditions and management. In addition, 23 % of respondents indicated encountering problems related to not having adequate information about a patient "often" to "almost always." The most common insufficient aspects of discharge communication were: advanced directives/code status (55 %), how to contact the appropriate hospital clinician with questions (55 %), and the appropriate clinician (e.g., primary care provider, hospital clinician) to contact with questions (50 %). Altogether, 86 % of respondents found it "somewhat difficult" or "difficult" to reach the appropriate physician with questions after discharge. Additionally, respondents indicated having insufficient access to information on care plans related to: physical or occupational therapy issues (45 %), follow up plans for labs or imaging studies pending at the time of discharge (33 %), and indication and planned duration for lines or catheters (33 %). Most respondents (86 %) indicated that internet-based access to the hospitals electronic medical record (EMR) would be important to help manage patients.

CONCLUSIONS: In this study, we performed a unique survey of home health care organizations in which we identified perceptions of quality gaps in the completeness of medical information provided to home health care clinicians and staff. As a next step, these individuals will be provided with internet-based access to the hospital EMR. We plan to repeat this survey 6 months following implementation of internet-based EMR access to determine which components of information exchange improve with this intervention and which require alternative interventions to drive improvement.

HOSPITALIST CAREER DECISIONS AMONG INTERNAL MEDICINE RESIDENTS John Ratelle¹; Denise Dupras²; Patrick C. Alguire³; Philip Masters³; Arlene Weissman³; Colin P. West^{4,5}. ¹Mayo Clinic, Rochester, MN; ²Mayo Clinic, Rochester, MN; ³American College of Physicians, Philadelphia, PA; ⁴Mayo Clinic, Rochester, MN; ⁵Mayo Clinic, Rochester, MN. (Tracking ID #1904482)

BACKGROUND: Since its inception in the mid-1990s, hospital medicine (HM) has grown into a distinct field of medical practice including more than 30,000 physicians, most of whom are trained in Internal Medicine. Despite its growth, little is known about internal medicine residents' decisions to pursue careers in HM. To meet this knowledge gap, we sought to identify which internal medicine residents choose a career in HM and how that choice changes over the course of their training.

METHODS: We conducted an observational cohort study of postgraduate year 3 (PGY-3) residents who completed the annual Internal Medicine In-Training Examination (IM-ITE) in 2009–2011. Survey questions addressed self-reported career plans, and linkage to National Board of Medical Examiners (NBME) records allowed analysis by program type (categorical or primary care), sex, and medical school location (United States or international). Results were linked to each resident by unique identifiers to allow analysis of changes in career plan across postgraduate years 1, 2, and 3.

RESULTS: We analyzed data from the 16,781 PGY-3 residents who completed the IM-ITE survey, representing 77.7 % of the 21,608 PGY-3 internal medicine residents in training in the 2009–2010, 2010–2011, and 2011–2012 academic years. 1552 (9.3 %) of these 16,781 PGY-3 residents reported HM as their ultimate career choice. Categorical residents were more likely than primary care track residents to report a hospitalist career plan in PGY-3 (9.8 % vs. 3.5 %, adjusted odds ratio (aOR) 3.19, 99 % CI 2.11–4.83, $p < 0.001$). Men were more likely than women to report a hospitalist career plan (9.8 % vs. 8.5 %, aOR 1.16, 99 % CI 1.01–1.33, $p=0.007$). Among categorical residents, hospitalist career plans did not differ for United States and international medical graduates (9.8 % in both groups), while among primary care track residents, United States medical graduates were more likely to report a hospitalist career plan (5.7 % vs. 1.8 %, aOR 3.64, 99 % CI 1.59–8.31, $p<0.001$). Among the 9501 residents completing the survey in all 3 years of training, only 276 (2.9 %) indicated a hospitalist career plan during the PGY-1 year, compared with 450 (4.7 %) in PGY-2, and 951 (10.0 %) in PGY-3. Among these 951 PGY-3 residents, 128 (13.5 %) originally made this decision in PGY-1, 192 (20.2 %) in

PGY-2 and 631 (66.4 %) in PGY-3. Only 87 (9.1 %) of these residents maintained a career decision in HM during all 3 years of training. Overall, 148 (53.6 %) of the 276 residents with a hospitalist career plan during PGY-1 reported a different career plan during PGY-3. Of these residents who changed career plans away from HM, 74 (50.0 %) planned a general medicine career and 64 (43.2 %) reported a subspecialty career. For the 823 residents with a hospitalist career plan during PGY-3, but not during PGY-1, 221 (26.9 %) had planned to be general medicine physicians and 445 (54.1 %) had previously reported a subspecialty plan.

CONCLUSIONS: Hospital medicine is a reported career choice for a significant proportion of graduating internal medicine residents. However, most residents do not finalize this decision until their final year of training. Additionally, the majority of residents who indicated HM as a career interest during PGY-1 indicate plans for an alternative career path by PGY-3. Further study is required to understand the reasons for these career plan shifts and to inform the best educational structures for hospitalist training.

HOSPITALIZATION-ASSOCIATED DISABILITY IN OLDER ADULTS IN A SAFETY NET HOSPITAL Anna H. Chodos¹; David Guzman³; S. Ryan R. Greysen⁴; Jeffrey Critchfield²; Urmimala Sarkar³; L. E. Goldman³; Margot Kushel³; Edgar Pierluissi^{1,2}. ¹UCSF, San Francisco, CA; ²UCSF, SFGH, San Francisco, CA; ³UCSF, SFGH, San Francisco, CA; ⁴UCSF, San Francisco, CA. (Tracking ID #1938146)

BACKGROUND: Hospitalization-associated disability (HAD) affects one-third of adults over 70 years old and predicts future disability and death. Adults cared for at safety net hospitals may be at risk of HAD at younger ages given the higher prevalence of risk factors for premature disability, such as low socioeconomic status. We measured the incidence of HAD by age group and examined associated risk factors in hospitalized adults at a safety net hospital.

METHODS: We measured functional outcomes of 548 patients 55 years and older who spoke English, Spanish, or Chinese, and were admitted to the San Francisco General Hospital, a safety net hospital. Participants' functional status at baseline (2 weeks prior to admission) and 30 days post-discharge was ascertained by self-report of ADL function. The outcome measure was new or additional disability in 1 or more ADL. Functional outcomes by age group were compared using chi-square tests. Logistic regression was used to identify associated risk factors for new or additional disability at 30 days.

RESULTS: Most participants were functionally independent at baseline. HAD was common in all age groups but it was the lowest in the middle age group, 65–69 years old, and significantly higher in the oldest group compared to all others. (See Table).

CONCLUSIONS: In adults at a safety net hospital, HAD at 30 days post-hospitalization occurred in almost as many adults 55–59 years old as 70–79 (30 %), which is similar to the proportion in the general population among adults 70 and older. Risk for HAD was significantly higher in the oldest group, ≥ 80 , compared to all other groups. In safety net hospitals, aggressive interventions that prevent and modify disability are needed and should also target adults younger than 65.

Hospitalization-Associated Disability at 30 Days by Age Group

Age, years	No Baseline Disability N (Row %)	Incidence of HAD at 30 days Row %	P-value for HAD at 30 days*	Odds Ratio for HAD at 30 days** (95 % CI)
55–59	97 (73.5 %)	25.8 %	$p=0.151$	1.80 (0.81, 4.01)
60–64	155 (80.7 %)	22.4 %	$p=0.342$	1.28 (0.59, 2.75)
65–69	71 (87.7 %)	17.3 %	reference	1.0
70–79	61 (66.3 %)	29.4 %	$p=0.063$	1.28(0.55, 2.97)
≥ 80	27 (52.9 %)	62.8 %	$p<0.001$	4.96 (1.98, 12.41)

HOW AN INTERVENTION TO HELP PREGNANT WOMEN USE PUBLICLY AVAILABLE PEDIATRIC QUALITY DATA AFFECTS THEIR TRUST IN THE INTERNET AS A SOURCE FOR THESE DATA Yara Youssef^{1,2}; Penelope S. Pekow^{1,2}; Peter K. Lindenauer^{1,4}; Jasmin L. Roberts¹; Katharine O. White^{1,5}; Kathleen M. Mazor^{2,3}; Sarah L. Gott^{1,4}. ¹Baystate Medical Center, Springfield, MA; ²University of Massachusetts Amherst, Amherst, MA; ³University of Massachusetts Medical School/Meyers Primary Care Institute, Worcester, MA; ⁴Tufts University School of Medicine/CTSI, Boston, MA; ⁵Baystate Medical Center, Springfield, MA. (Tracking ID #1935060)

BACKGROUND: IDEAS for a Healthy Baby is a randomized trial that examines whether helping pregnant women use publicly available pediatric quality data impacts their choice of pediatrician. Women randomized to the intervention group received an information session with a trained patient navigator who assisted them in using a website that reports pediatric quality data. Women randomized to the control group received a pamphlet that explained what quality data is, why it is important, and that included the web-address for the website used in the intervention.

METHODS: English-speaking women ages 16–50 between 20 and 34 weeks of gestation who attended a prenatal clinic that serves a low income population were enrolled between May and December 2013. As part of the baseline survey, participants were asked to rate how much they trust various sources of health quality information (e.g., friends, family, coworkers, the internet, social media) using a four-point Likert scale. Trust was again measured after the intervention to determine if changes in trust had occurred in the intervention and control groups. Health literacy was assessed using the Newest Vital Sign. Responses were collapsed into “high” and “low” trust. Wilcoxon matched-pairs signed-ranks test were used to assess changes in trust in sources of health quality information from baseline to follow-up.

RESULTS: Among participants with complete baseline and follow-up data ($n=189$; 102 intervention/87 control), the median age was 25; 57 % were Hispanic, 25.6 % White, and 18.9 % Black. 33.5 % of women had completed <12 years of education; 34.1 % earned <\$20,000/year; 76.2 % scored in the “possible” to “likely” limited health literacy range. There was no baseline difference in the level of trust in the internet between the intervention and control groups (40.8 % vs. 43.1 %, $p=0.10$). There was a significant increase in trust in the internet in the intervention group (40.8 % vs. 52.8 %, $p<0.05$); there was no change in trust in the internet in the control group (43.1 % vs. 40 %, $p=0.81$). A substantial proportion of participants in both the intervention and control groups reported a high level of trust in family as a source of information about health care quality (88.3 % and 87.4 %) with fewer participants reporting high levels of trust in friends (68.2 % and 64.9 %) or coworkers (43.5 % and 46.5 %) at baseline. There were no significant changes in levels of trust for these other sources after the intervention.

CONCLUSIONS: Participation in an intervention to enable use of publicly reported pediatric quality data was associated with an increase in trust in the internet as a source of health quality information. A pamphlet that provided information about health quality information and a link to the website did not have the same effect. Trust in other sources such as friends, family and coworkers did not significantly change in either the intervention or control groups. The greater increase in trust in information found on the internet in patients who viewed the information with a patient navigator compared to patients who only received written information about the website may indicate a role for facilitated review of this information for low-income, low health-literacy populations.

HOW CAN EHEALTH TECHNOLOGY ADDRESS MULTIMORBIDITY CHALLENGES? PERSPECTIVES FROM PATIENTS WITH MULTIPLE CHRONIC CONDITIONS Donna M. Zulman^{1,2}; Emily Jenchura⁴; Danielle Cohen²; Eleanor Lewis¹; Thomas Houston³; Steven Asch^{1,2}. ¹VA Palo Alto Health Care System, Menlo Park, CA; ²Stanford University, Stanford, CA; ³Bedford VA Medical Center, Bedford, MA; ⁴Arizona State University, Tempe, AZ. (Tracking ID #1939564)

BACKGROUND: eHealth technology such as personal health records, web-based disease management programs, and mobile applications can support patient self-management and health care navigation. These tools, however, are frequently disease-specific in design. Optimization of eHealth tools for patients with multiple chronic conditions requires an understanding of challenges and technology needs specific to multimorbidity.

METHODS: We conducted a qualitative needs assessment of patients with multiple chronic conditions from an academic medical center and a Veterans Affairs facility. A screening questionnaire was used to identify 330 patients with ≥ 3 chronic conditions and with experience using health-related technology. We used purposive sampling to construct 10 groups of 3–8 patients, grouping individuals by age, sex, primary health care setting, and a common chronic condition to facilitate discussion. A trained facilitator moderated the focus groups using a semi-structured guide based on the Fit between Individual, Task, and Technology (FITT) framework to elicit discussion about 1) challenges that patients face when they have multiple chronic conditions, and 2) patients’ use of technology—and opportunities to enhance technology—to address these challenges. Standard content analysis methods were used to code textual data from focus group transcripts. Three investigators generated preliminary codes based on the FITT framework, and two investigators independently read and coded all transcripts using ATLAS.ti software. Emergent themes were reviewed with all

collaborators, and final themes and representative quotes were validated through a follow-up survey with a sample of focus group participants.

RESULTS: Among focus group participants ($n=53$), the mean (SD) number of chronic conditions was 5(2) with the most common including hypertension (75 %), chronic pain (64 %), arthritis (49 %), diabetes (34 %), and depression (40 %). Patients described using technology most frequently to search for health information (96 %), communicate with health care providers (92 %), track medical information (83 %), track medications (77 %), and support decision-making about treatment (55 %). Focus group discussions yielded three overarching themes about multimorbid patients’ challenges that may be amenable to eHealth technology support: 1) Needing to serve as expert and advocate because of a unique combination of health issues (“You have to be your own advocate and research everything you can because sometimes you will be more cutting-edge than your doctor”); 2) Managing a high volume of information, visits, and self-management tasks (“I can save myself easily 15 or 20 visits a year just by messaging my primary or my neurologist”); and 3) Coordinating, synthesizing, and reconciling information from different providers and about different conditions (“My illness crosses so many specialty boundaries...I am always playing tag between one of four doctors”). Several desirable eHealth tools emerged from discussions, including resources that retrieve and synthesize information about multiple conditions and medications, applications that manage tasks and health records across multiple healthcare systems, tools that facilitate communication with multiple providers, and social media that connects patients with similar conditions.

CONCLUSIONS: Patients with multiple chronic conditions have holistic, rather than condition-specific, needs from eHealth technology, and desire tools that reconcile information about different conditions and enhance communication across providers and systems.

HOW DO PATIENTS PERCEIVE BREAST DENSITY? A QUALITATIVE STUDY Erin N. Marcus^{1,4}; Monica Yepes^{2,4}; Noella Dietz^{3,4}. ¹University of Miami Miller School of Medicine, Miami, FL; ²University of Miami Miller School of Medicine, Miami, FL; ³University of Miami Miller School of Medicine, Miami, FL; ⁴University of Miami Miller School of Medicine, Miami, FL. (Tracking ID #1939566)

BACKGROUND: Breast density is a radiologic term denoting the degree of opacity of breast tissue on mammographic imaging. Mammography is less sensitive in women with dense breasts. Supplemental ultrasound can help detect additional cancers in these women, but it also results in a significant increase in biopsies and imaging of noncancerous lesions. Some patient groups have urged that all women be told about their breast density and advised to consider additional testing for cancer. More than a dozen states now require that breast centers convey density findings to individual patients in writing with mammogram results. Little is known about women’s baseline understanding of the concept of breast density and about optimal ways to convey this information.

METHODS: Focus groups are being conducted with women who underwent screening mammography at a high volume academic medical center in 2013 and were found to have dense breasts with no suspicious lesions. The center routinely includes breast density information in the result letters it sends to patients, even though Florida state law does not require this. Women ages 40–69 with no history of breast cancer are eligible. All women meeting eligibility criteria were sent post cards providing them with the choice of opting out of a recruitment call. At least 3 attempts have been made to all women who did not opt out. Content analysis using a grounded theory approach is ongoing.

RESULTS: Thus far, 27 English-speaking women have participated in 4 groups. Participants’ ages range from 42 to 67. Ten women self-identified as Hispanic, 8 as Black, 5 as white non-Hispanic, and 4 as Asian. Repeated themes include confusion about the term “dense breasts” and the benefits of additional testing, as well as a fear that increased density is associated with a higher risk of cancer. Women liked print materials that included mammogram images showing normal, heterogeneous, and extremely dense breast tissue. Women stated they wanted a clear explanation of the potential financial costs of additional testing. Two more English and two Spanish focus groups are planned.

CONCLUSIONS: Simply adding language about density to patient result notification letters is inadequate to ensure these findings are communicated effectively. Our results suggest a need for tools to improve breast density understanding so that women can make an informed decision about additional breast imaging. Policymakers should keep in mind potential public confusion about this complex topic when crafting future density notification laws.

HOW DOES THE NUMBER OF BARRIERS TO CARE AFFECT TIMELINESS OF FOLLOW-UP AMONG WOMEN WITH ABNORMAL CANCER SCREENING TESTS IN THE PATIENT NAVIGATION RESEARCH PROGRAM? Ambili Ramachandran¹; Frederick R. Snyder²; Elizabeth Calhoun³; Donald J. Dudley⁴; Steven R. Patierno⁵; Tracy A. Battaglia⁶; On behalf of the Patient Navigation Research Program⁷. ¹Boston University School of Medicine, Boston, MA; ²NOVA Research Company, Bethesda, MD; ³University of Illinois at Chicago, Chicago, IL; ⁴University of Texas Health Science Center, San Antonio, TX; ⁵The George Washington University, Washington, DC; ⁶Boston University School of Medicine, Boston, MA; ⁷Patient Navigation Research Program, Rockville, MD. (Tracking ID #1931236)

BACKGROUND: Patient navigation (PN) programs were designed to address barriers to cancer care among underserved populations in order to improve access to timely care. While there is widespread dissemination of PN programs nationwide, there is a paucity of research examining the association of barriers and clinical outcomes within navigation programs. Better understanding of this relationship would help to guide improvements and adaptations of PN programs.

METHODS: We conducted a secondary analysis of the multicenter Patient Navigation Research Program (PNRP) using data from the intervention arms of seven sites that navigated women for abnormal breast or cervical cancer screening tests from 2006 to 2010. The independent variable was barriers to care documented by navigators during encounters with subjects. Barriers were characterized by quantity (0, 1, 2, 3+) and specific type. The dependent variable was median number of days to diagnostic resolution, defined by the time interval from index screening event to definitive diagnosis of cancer or no cancer, estimated using Kaplan-Meier cumulative incidence curves. Breast ($n=2600$) and cervical ($n=1387$) subjects were analyzed separately. Using chi-square tests, we compared subjects with and without barriers by socio-demographic characteristics. We then conducted descriptive statistics to examine specific barrier types and to describe the association of barrier quantity and navigation efforts (total number of encounters and total time spent by the navigator). Using log-rank tests, we compared median days to resolution by barrier quantity.

RESULTS: In both screening groups, compared to women without barriers, those with at least one barrier were more likely to be of minority race, non-English language speakers, and uninsured ($p<0.0001$). The most common barriers identified were health insurance (24 %), system problems scheduling care (23 %), language (18 %), and fear (18 %). As the number of barriers increased, total number of encounters and total time spent by the navigator increased significantly ($p<0.0001$). Breast subjects were more likely than cervical subjects to have at least one barrier to care (74 % vs. 55 % respectively, $p<0.0001$). For both breast and cervical subjects, women with an intermediate number of barriers (1 or 2) had the longest time to resolution, while those with none or many (3+) had the shortest time to resolution. Among breast subjects, median time to resolution for those with 0 barriers or 3+ barriers was 52 days (95 % CI 45,62) and 60 days (95 % CI 54,68); whereas women with 1 or 2 barriers had median time to resolution of 83 (95 % CI 65,104) and 81 days (95 % CI 60,97). The median time to resolution among cervical subjects for those with 0 barriers or 3+ barriers was 75 days (95 % CI 69,80) and 69 days (95 % CI 62,80), while women with 2 barriers had longer time to resolution [102 days (95 % CI 84,139)].

CONCLUSIONS: In a multicenter study of patient navigation, those with barriers were among the most vulnerable. For both breast and cervical subjects, we found that women with the most barriers resolve cancer screening abnormalities as quickly as women with no barriers. However, women with an intermediate number of barriers experience a longer delay until definitive diagnosis. Future analyses will explore if this pattern may be explained by intensity of navigation or types of barriers.

HOW INPATIENT MEDICINE TEAMS MAKE SENSE OF THEIR PATIENTS AND TASKS: ROUNDING PATTERNS, PATIENT DISCUSSIONS, AND CLINICAL OUTCOMES Luci Leykum²; Hannah Chesser¹; Carla Pezzia¹; Holly Lanham¹; Jacqueline Pugh²; Ray Palmer¹; Jamie Kohn⁵; Heather S. Reisinger³; Michael Agar⁴. ¹University of Texas Health Science Center at San Antonio, San Antonio, TX; ²STVHCS/UTHSCSA, San Antonio, TX; ³Iowa City VA/Univ Iowa, Iowa City, IA; ⁴Ethknoworks, Santa Fe, NM; ⁵Kenan-Flagler Business School, UNC Chapel Hill, Chapel Hill, NC. (Tracking ID #1934905)

BACKGROUND: Recent literature explores how relationships among providers influence patient outcomes. Relationships may influence providers' ability to engage in sensemaking, or how they come to understand what is happening with their patients and act based on their understanding. We examined sensemaking among inpatient medical teams, assessing patterns of team sensemaking and their association with patient outcomes of unnecessary length of stay (ULOS) and complication rates.

METHODS: We observed 11 inpatient teams in 2 teaching hospitals over 2 to 4 week periods, rounding with them daily. We took detailed field notes regarding team activities and

audiotaped rounds. We assessed sensemaking in two ways: first, by how the team made sense of what they needed to do on rounds, and second, by how they made sense of individual patients' clinical courses. To assess how teams made sense of their rounding tasks, we examined the order in which they rounded. We categorized rounding order as: "gravity," starting at the highest floor and moving down; "geography," starting on a particular unit and then moving to the next units; "intern by intern," rounding on one intern's patients first and then the other's; "running the board," sitting in the team room and rounding; and "patient-driven," rounding based on patients' clinical needs. We assessed the number of rounding patterns per team, hypothesizing that use of a greater number of patterns indicated that the team was better able to make sense of their clinical tasks and round accordingly. To assess sensemaking of individual patients, we listened to audiotaped discussions of 4 patient encounters. Two encounters were of complex patients on post-call days, and 2 were of patients who had complications. Complications were defined as the development of a new problem, or a clinical deterioration after at least 24 hours of stability. We used Charlson Comorbidity Score and presenting symptoms to sample post-call discussions, and Charlson and type of complication to sample patients with complications. We then applied the situation, task, intent, concern, calibrate (STICC) framework, assessing whether patient discussions included each of these elements. We gave each team a score from 0 to 4 for each STICC element, reflecting whether we heard the element in each of the 4 patient encounters. We then summed the scores from each element to obtain a total "STICC Score." We assessed the association between number of rounding patterns, STICC score, and ULOS and complications using regression analysis. All analyses were adjusted for Charlson score, mental illness, and team workload.

RESULTS: Teams who used a higher number of rounding patterns and whose patient discussions reflected Intent had significantly lower ULOS ($p=0.01$ and 0.04). Use of more rounding patterns was associated with fewer complications ($p=0.02$), as were use of task, intent, and total STICC score in patient discussions ($p=0.02$, <0.001, 0.01).

CONCLUSIONS: Inpatient teams differ in how they round and discuss individual patients, and these differences are associated with patient outcomes. A shared understanding of the intent of the treatment plan may be particularly important for effective patient care, as may consideration of patient needs in rounding order. Improving sensemaking among clinical teams may be an important strategy for improving patient outcomes.

HOW OFTEN ARE CATHETER-ASSOCIATED URINARY TRACT INFECTIONS THAT ARE IDENTIFIED FOR NATIONAL HEALTHCARE SAFETY NETWORK SURVEILLANCE REPORTING ALSO NOTED AS DIAGNOSES IN CLAIMS DATA? Jennifer Meddings; Heidi Reichert. University of Michigan, Ann Arbor, MI. (Tracking ID #1939737)

BACKGROUND: Since 2008, claims data descriptions of urinary tract infections are used to determine whether the condition is a payable comorbidity, or is one of certain hospital-acquired conditions (such as catheter-associated urinary tract infection, CAUTI) for which hospitals no longer receive additional payment. Hospital CAUTI rates from claims data were publicly reported on Medicare's 'Hospital Compare' website from 2011 and 2013. Since January 2012, hospitals have been required to collect CAUTI data for patients in intensive care units (ICUs) using criteria from the Center's for Disease Control and Prevention and National Healthcare Safety Network (NHSN); these NHSN CAUTI events are publicly reported on 'Hospital Compare.' Our objective was to assess how often ICU patients with CAUTI events reported for NHSN surveillance were also noted to have a CAUTI diagnosis in the discharge claims data (which includes diagnoses from ICU and non-ICU days during hospitalization).

METHODS: We first performed a retrospective analysis of 6 months of patient-level infection control data for all adult and pediatric ICU patients from one large academic tertiary care hospital, to identify patients with at least one NHSN CAUTI event reported as acquired while in the ICU. We next performed a retrospective analysis of the discharge claims data that was submitted for payment for these patients' hospitalizations. We identified claims data cases of CAUTI by having the ICD-9-CM diagnosis code 996.64 (infection or inflammation due to an indwelling urinary catheter); cases of UTI without catheter-association were identified by having at least one of 10 potential ICD-9-CM UTI codes listed among all diagnoses in the claims data without the 996.64 code.

RESULTS: Of the 4,522 adult and pediatric ICU patients admitted between January 1, 2012 and June 30, 2012, 56 patients were identified as having one or more CAUTI events during the ICU stay according to the infection control NHSN data. By claims data, 5 (9 %) of these 56 patients were identified as having a hospital-acquired CAUTI by the diagnosis code 996.64; 37 (66 %) were identified as having a UTI without catheter-association, of which 25 UTIs were noted as hospital-acquired. Of the 56 patients with NHSN CAUTI events, 14 (25 %) were not identified in claims data as having either CAUTI or UTI events.

CONCLUSIONS: CAUTI events reported by the CDC's National Healthcare Safety Network as hospital-acquired infections for comparing hospital performance are rarely identified as CAUTI diagnoses in claims data, which requires an accurate description of the UTI to identify it as a payable or non-payable comorbidity. NHSN CAUTI events (identified by infection preventionists using laboratory data and symptoms as documented in the medical

record) may not be listed as diagnoses in claims data (generated by hospital coders based upon descriptions of UTIs in physician notes) because physicians may not recognize and/or document the UTIs as catheter-associated, or because physicians apply different criteria for clinical diagnosis of CAUTI compared to the NHSN surveillance definitions. Consequently, hospitals may be receiving additional comorbidity payment for hospital-acquired CAUTI events being reported to the NHSN surveillance system, because two mandatory and resource-intensive data collections (NHSN data and claims data) for identifying hospital-acquired conditions are occurring in parallel, without communication between them.

HOW WELL DOES MEDICARE'S VTE-1 CORE MEASURE CAPTURE HOSPITAL PERFORMANCE FOR VENOUS THROMBOEMBOLISM PROPHYLAXIS? Claire Griffiths¹; Marc Moote¹; Carol Becker¹; Julie Wietzke¹; Amy N. Brant¹; Daniel Nielsen¹; Steven J. Bernstein^{1,2}; Scott A. Flanders¹. ¹University of Michigan, Ann Arbor, MI; ²US Department of Veterans' Affairs, Ann Arbor, MI (Tracking ID #1928904)

BACKGROUND: Venous thromboembolism (VTE), including pulmonary embolism and deep-vein thrombosis, is an important cause of preventable morbidity and mortality, and commonly occurs in the setting of hospitalization. Pharmacologic and mechanical prophylaxis are effective at preventing VTE and it is recommended that all patients admitted to the hospital be screened for VTE risk and given prophylaxis when indicated. The Centers for Medicare and Medicaid Services (CMS) has accordingly developed a set of 6 Core Measures of hospital performance for the prevention of VTE. The first of these measures, VTE-1, assesses whether at least 1 dose of pharmacologic prophylaxis or use of mechanical prophylaxis was provided to patients during hospital day 1 or 2 when indicated. However, the administration of a single dose of prophylaxis is not necessarily an accurate measure of hospital VTE prophylaxis performance as high performing hospitals should accurately assess risk, capture contraindications to pharmacologic prophylaxis, and deliver appropriately dosed VTE prophylaxis throughout the duration of a patient's hospital stay. The Michigan Hospital Medicine Safety Consortium (HMS), a multi-hospital quality collaborative, collects detailed data regarding VTE prophylaxis provided during hospitalization, allowing a comparison of hospital performance by the current CMS VTE-1 measure to a more rigorous definition developed by HMS.

METHODS: Data were collected from 21 participating hospitals from January to June, 2013. For VTE-1, CMS requires that each hospital randomly sample medical records of non-ICU patients >18 years old and report the rate at which patients receive any dose of pharmacologic or mechanical prophylaxis on day 1 or 2 of hospitalization or have a documented reason why prophylaxis was not given. CMS data were collected from an average of 229 patients per hospital (range 201–292), and CMS VTE-1 performance for each hospital was determined by using the average of monthly rates over the 6 month study period. HMS data were collected by trained medical record abstractors from an average of 369 non-ICU, non-surgical patients per hospital (range 324–401). Appropriate VTE prophylaxis by HMS criteria was defined as receipt of appropriately dosed pharmacologic prophylaxis on hospital day 1 or 2 for patients at high risk of VTE as determined by Padua risk score. High risk patients with contraindications to pharmacologic prophylaxis not receiving anticoagulants required an order for mechanical prophylaxis on day 1 or day 2. Hospitals were first placed into performance quartiles based on CMS VTE-1 rates of prophylaxis, and were then re-ranked by performance quartile based on the HMS appropriate prophylaxis definition.

RESULTS: Using the CMS VTE-1 performance measure, a mean of 92.1 % of patients (hospital performance range: 71.6 % to 99.6 %) met CMS core measure criteria for adequate VTE prophylaxis at all hospitals. The mean rate of prophylaxis and ranking of each hospital by performance quartile is shown in Fig 1. Using the HMS definition, only 72.5 % of patients (hospital performance range: 41.1 % to 90.5 %) received appropriate prophylaxis. Of the 5 hospitals in the top-performing quartile for the CMS measure, 2 hospitals (40 %) shifted to a lower quartile using the HMS performance criteria, 1 of which dropped to the bottom quartile. Of the 6 lowest performing hospitals by CMS criteria, 3 hospitals (50 %) moved out of the bottom quartile when ranked by the HMS performance criteria. In all, 13 hospitals (62 %) moved by 1 or more quartiles using the more rigorous HMS criteria (Fig 2).

CONCLUSIONS: Comparisons of hospital performance for VTE prophylaxis vary considerably based on the definition used for appropriate prophylaxis. A more rigorous, guideline-based definition of appropriate prophylaxis resulted in a shift of performance quartile for over 60 % of hospitals. As hospitals are increasingly being rewarded and penalized based on their performance by these measures, more effort is needed to better understand and address the limitations of existing measures.

HYPERTENSION IN WESTERN ALASKA NATIVE PEOPLE: THE WESTERN ALASKA TRIBAL COLLABORATIVE FOR HEALTH (WATCH) STUDY
Stacey E. Jolly¹; Kathryn R. Koller²; Jesse Metzger²; Scarlett Hopkins³; Bernadette Boden-Albala⁴; Bert Boyer⁵; Sven O.E. Ebbesson³; Barbara V. Howard⁵; Jason G. Umans⁵. ¹Cleveland Clinic, Cleveland, OH; ²Alaska Native Tribal Health Consortium, Anchorage, AK; ³University of Alaska-Fairbanks, Fairbanks, AK; ⁴Mount Sinai Hospital, New York, NY; ⁵MedStar Research Institute, Washington DC, DC. (*Tracking ID #1918808*)

BACKGROUND: Hypertension (HTN) is a common and an important risk factor for cardiovascular diseases (CVD), such as stroke, heart disease, and heart failure. Estimates of HTN among Alaska Native people are lacking from national surveys, yet CVD is increasing in this population; thus we assessed the prevalence of HTN, risk factors, awareness and treatment among western Alaska Native people.

METHODS: This cross-sectional analysis from the Western Alaska Tribal Collaborative for Health (WATCH) study, comprised of four epidemiologic cohort studies from 2000 to 2010, includes Alaska Native adults ≥ 18 years of age from the Norton Sound and Yukon-Kuskokwim regions of Alaska. Participants were categorized as having HTN if they had systolic blood pressure ≥ 140 mmHg, diastolic blood pressure ≥ 90 mmHg, were taking blood pressure medication at the time of entry into the study, and/or had a diagnosis of HTN in their medical record. Covariates examined were age, body mass index (BMI), glycemic status, smoking (current/former vs. never), triglycerides (TG), and high-density lipoprotein cholesterol (HDL-C). Obesity was defined as a BMI ≥ 30 kg/m². Diabetes and impaired fasting glucose were defined using 2010 American Diabetes Association criteria. High TG and low HDL-C were defined using 2002 National Cholesterol Education Program guidelines for metabolic syndrome. HTN awareness was by self-report, HTN treatment was defined by use of prescribed blood pressure medication, and HTN control was a baseline blood pressure $<140/85$ mmHg with concurrent use of blood pressure medication. U.S. General Population estimates are from NHANES.

RESULTS: Of the 4,569 participants, 54 % ($n=2,453$) were women. Mean age was 41 years (SD ± 16). One quarter, 25 % ($n=1,138$) had prevalent HTN; U.S. general population prevalent HTN is about 33 %. Women (27 %) had more HTN than men (23 %); HTN increased with age with 50 % of participants aged 55–64 years and nearly 70 % of those 65 years and older having HTN. The prevalence of HTN in the Yukon-Kuskokwim region was 28 % vs. 21 % in the Norton Sound region. Prevalent diabetes was 5 % ($n=219$) and impaired fasting glucose was 23 % ($n=1,047$); 71 % ($n=3,222$) were current/former smokers. In multivariate analysis, age, obesity, elevated triglycerides, and impaired fasting glucose were independently associated with HTN prevalence (see table). Of the people with HTN, 64 % ($n=731$) were aware of their condition. Of the 700 participants with HTN and for whom medication data was available, 61 % ($n=428$) were on blood pressure medication, and 39 % ($n=273$) were controlled. Among U.S. general population, 52 % have controlled HTN.

CONCLUSIONS: HTN in western Alaska Native people was less prevalent than in the U.S. general population and efforts to understand the protective factors are needed. Important correlates of risk for HTN were age, obesity, and high triglycerides. Data on awareness, treatment and control suggest the need for programs to better control HTN among those with it and stem the tide of rising cardiovascular disease.

Multivariate Regression Analysis of Independent Risk Factors for Prevalent HTN among Western Alaska Native People

	Odds Ratio (95 % Confidence Interval)
Sex (Female vs Male)	0.95 (0.80–1.13)
Age (referent is 18–34 years) 35–44	2.41 (1.89–3.08)
45–54	4.23 (3.30–5.42)
55–64	11.41 (8.72–14.94)
65+	27.12 (20.12–36.51)
Region (referent is Yukon-Kuskokwim) Norton Sound	0.51 (0.42–0.61)
Body Mass Index (≥ 30 vs <30)	2.31 (1.93–2.78)
Impaired Fasting Glucose	3.29 (2.30–4.71)
Prevalent Diabetes	1.11 (0.92–1.34)
Current/Former Smoker	0.74 (0.61–0.88)
Triglycerides (≥ 150 vs <150)	2.19 (1.76–2.72)
Low HDL (<40 for men; <50 for women)	0.89 (0.71–1.12)

IDENTIFYING AND DISCOURAGING OVERUSE IN AMBULATORY CARE: THE SWISS LESS IS MORE PROJECT Kevin Selby¹; Joana Le Boudec¹; Jean-Michel T. Gaspoz²; Arnaud Perrier²; Meier A. Christoph^{3,2}; Andreas Zeller⁴; Nicolas Rodondi⁵; Stefan Neuner-Jehle⁶; Jacques Cornuz¹. ¹University of Lausanne, Lausanne, Switzerland; ²University of Geneva, Geneva, Switzerland; ³Triemli Hospital, Zurich, Switzerland; ⁴University of Basel, Basel, Switzerland; ⁵University of Bern, Bern, Switzerland; ⁶University of Zurich, Zurich, Switzerland. (*Tracking ID #1929778*)

BACKGROUND: There is a growing movement in several countries to identify and list low-value healthcare activities so as to discourage their use, with the goal of reducing waste and avoiding harm to patients. In 2012, the Swiss Society for General Internal Medicine launched a process to create a list of activities to be avoided in Swiss primary care. Given differences in practice patterns between countries and the potential controversies surrounding such a list, a transparent process was needed to adapt international lists to the local context.

METHODS: A literature review of similar initiatives was performed to identify low-value healthcare lists in the US, UK et Australia. Recommendations with little relevance to ambulatory internal medicine were excluded. A panel of experts from throughout Switzerland participated in an online, modified Delphi process to rank international recommendations and propose additional low-value health care activities commonly performed in Switzerland.

RESULTS: 1090 recommendations were identified. Nine hundred thirty-two recommendations were excluded because they were not relevant to primary care and 91 were excluded because they were poorly substantiated or were recommendations of activities ‘to do’, leaving 38 unique recommendations relevant to ambulatory general internal medicine. Thirty-five Swiss experts ranked items based on their agreement with each statement, and suggested 12 new recommendations using a modified Delphi process. The average agreement score of the 50 items was 8.52/10 (SD=0.80). In a third round, the top 18 recommendations were re-ranked based on perceived frequency, costs and potential

harms to patients. To ensure that an initial 'do not do' list would have a potential large impact on primary care, the top 10 items based on frequency were identified (table).

CONCLUSIONS: Amongst Swiss experts, there is generally a high level of agreement with international recommendations to avoid low-value care. A score

based on frequency, costs and potential harms can provide a transparent way to measure the potential impact of recommendations.

Low-value healthcare activities to be avoided, ranked by frequency encountered in Swiss primary care

Rank	Recommendation	Agreement Score (0–10)	Impact Score (96–288)	Frequency Score (32–96)
1	Do not obtain imaging studies in patients with non-specific low back pain	9.56	212	94
2	Do not prescribe antibiotics for uncomplicated upper respiratory tract infections (URIs)	9.40	201	92
3	Do not perform the Prostate Specific Antigen (PSA) test to screen for prostate cancer without a discussion of the risks and benefits	9.59	211	90
4	Do not perform lab testing in patients with a clinical diagnosis of an uncomplicated upper respiratory tract infection (URI)	9.03	168	87
5	Do not continue pharmacological treatment of gastroesophageal reflux disease (GERD) with long-term acid suppression therapy without titrating to the lowest effective dose	9.50	196	82
6	Do not routinely prescribe antibiotics for acute mild-to-moderate sinusitis	9.50	186	81
7	Do not use antimicrobials to treat bacteriuria in immunocompetent older adults	9.16	180	80
8	Do not routinely obtain radiographic imaging for patients who meet diagnostic criteria for uncomplicated acute rhinosinusitis.	9.91	190	78
9	Do not obtain preoperative chest radiography in the absence of a clinical suspicion	9.26	168	77
10	Do not use dual-energy x-ray absorptiometry (DEXA) screening for osteoporosis in women younger than 65 or men younger than 70	9.16	169	72

Impact Score = Frequency + Cost + Harms

IDENTIFYING BARRIERS AND FACILITATORS TO IMPROVING THE IMPLEMENTATION OF WEIGHT MANAGEMENT SERVICES WITHIN A PATIENT-CENTERED MEDICAL HOME Melanie Jay^{1,3}; Sumana Chintapalli^{2,1}; Kathryn Oi^{2,1}; Allison Squires^{4,2}; Scott Sherman^{1,3}; Adina Kalet². ¹VA NY Harbor Healthcare System, New York, NY; ²NYU School of Medicine, New York, NY; ³NYU School of Medicine, New York, NY; ⁴NYU College of Nursing, New York, NY. (*Tracking ID #1920970*)

BACKGROUND: The Veterans Affairs (VA) Healthcare System uses Patient-Aligned Care Teams (PACT) as part of its patient-centered medical home model. "Teamlets" often consist of an RN, an LPN, a program assistant, and a PCP who are tasked with screening for obesity, providing brief interventions, counseling patients, and advising eligible patients to attend MOVE!, an intensive weight management program. While every VA hospital has a MOVE! Program to address the high prevalence of overweight and obesity among Veterans, less than 10 % of eligible patients attend even one session. Since Veterans visit PACT 3.6 times per year, there are opportunities to improve counseling and service coordination. A single-center, qualitative research study of healthcare team members assessed attitudes and practices as well as elicited barriers and facilitators to care implementation for overweight and obese patients.

METHODS: We recruited healthcare team members for individual key informant interviews using a combination of convenience and snowball sampling. We used a

semi-structured interview guide with questions informed by the Theory of Planned Behavior. Interviews lasted 30–60 min and were conducted by a general internist in a private office while a research assistant took field notes. The interviews were audio recorded and transcribed by a transcription company. Research assistants reviewed transcripts to correct mistakes and de-identify content. Analysts then used an iterative and directed coding approach, facilitated by NVivo software and structured by an initial coding guide developed from field notes and recollections. The primary coder segmented and coded each transcript, allowing additional codes to emerge. A second researcher then independently coded each segment. The researchers met frequently to harmonize codes and synthesize themes that emerged from coded transcripts.

RESULTS: There were 25 participants in the study (11 MD or NP, 5 RN, 2 RD, 5 LPN, 2 Other, with 6 holding an additional managerial role); 80 % were female, 48 % identified as White, 28 % African American, 16 % Asian, and 8 % Hispanic. Emerging themes included: system constraints, patient barriers, and perceived role responsibility. We found that performance measures and reminders motivate and shape current practices by the PACT teamlets. Barriers to treating patients included time, competing demands, and lack of understanding about what happens in the MOVE! Program. Facilitators included having received training in motivational interviewing (MI) and having a personal interest in nutrition and physical activity. Perceptions about role responsibility varied, with some RNs, LPNs, and MDs perceiving that they play important roles in weight management counseling, while others stated that it was the role of other team members. Similarly, perceived counseling competency varied within and between the different professions. For instance, some RNs and PCPs described in great detail how they used MI to counsel patients around weight, while others questioned whether they had adequate time and training.

CONCLUSIONS: These data allowed us to identify several approaches to improve weight management by the PACT teamlets and will inform the design of PACT-based weight management interventions. Findings, however, may be organization-specific, so replication of the study at other sites is necessary to determine common implementation issues.

IDENTIFYING PROVIDER FACTORS ASSOCIATED WITH PSA SCREENING AMONG ELDERLY VETERANS Victoria Tang^{1,2}; Ying Shi^{1,2}; Kathy Fung^{1,2}; Roxanne Espaldon^{1,2}; Jessica E. Tan^{1,2}; Louise Walter^{1,2}. ¹SFVAMC, San Francisco, CA; ²UCSF, San Francisco, CA. (*Tracking ID #192632*)

BACKGROUND: Despite guidelines recommending against prostate-specific antigen (PSA) screening in elderly men with limited life expectancy, screening is common. PSA screening is heavily dependent upon the health care provider; however, little is known about the provider-level determinants of PSA screening in elderly men with differing life expectancy. We sought to identify provider characteristics that are associated with PSA screening rates in elderly men with limited life expectancy and those with favorable life expectancy.

METHODS: We conducted a cross-sectional study of 636,413 men age 65+ years eligible for PSA screening and had laboratory tests performed at a VA in 2003. Men with limited life expectancy were defined as men age 85+ with Charlson score ≥ 1 or age 65+ with Charlson score ≥ 4 . Men with favorable life expectancy were defined as men age 65–74 with Charlson score = 0. We identified providers who ordered these patients' index screening PSA test or ordered the majority of their lab tests in 2003. The primary outcome was the percentage of men who had a screening PSA at a VA in 2003. The primary predictors were provider characteristics, including provider type, training level, gender, and specialty. We performed log-Poisson regression models for the association between each provider characteristic and PSA screening among men with limited life expectancy and favorable life expectancy, adjusting for patient characteristics (age, race, marital status, income, and education) and provider clustering.

RESULTS: Among 96,644 (15 %) men with limited life expectancy 42 % received PSA screening. Among 127,769 (20 %) men with favorable life expectancy 68 % received PSA screening. Higher PSA screening in men with limited life expectancy was associated with the following provider characteristics: training level (46 % for attendings versus 30 % for residents/fellows, $P < 0.001$), provider type (48 % for physician assistants versus 46 % for attending physicians and nurse practitioners, $P=0.002$), gender (44 % women vs 43 % men, $P<0.001$) and specialty (43 % Medicine vs 40 % Surgery, $P=0.007$). The same provider characteristics were associated with higher PSA screening in men with favorable life expectancy. All provider characteristics remained independently predictive of PSA screening in multivariate analyses except specialty, which was no longer predictive among men with limited life expectancy.

CONCLUSIONS: A significant percentage of men with limited life expectancy are receiving PSA screening. Practicing clinicians have substantially higher PSA screening rates than trainees regardless of patient life expectancy. Interventions to reduce PSA screening in elderly men with limited life expectancy should be targeted to high screening providers.

ILLEGITIMATE BUPRENORPHINE USE, AND ACCESS TO AND INTEREST IN BUPRENORPHINE TREATMENT Aaron Fox^{1,2}; Adam Chamberlain²; Taeko M. Frost³; Chinazo Cunningham^{1,2}. ¹Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine, Bronx, NY; ³Washington Heights CORNER Project, New York, NY. (*Tracking ID #1927780*)

BACKGROUND: In the United States, the opioid addiction epidemic is escalating; however, there is a large gap (nearly 1.5 million persons) between those in need of treatment and those who receive treatment. Primary care physicians have the opportunity to address this treatment gap by offering buprenorphine maintenance therapy (BMT), but access to treatment may not be adequate to meet the current demand. Recently, diversion of buprenorphine has received major media attention, where concerns were raised about illicit buprenorphine use to get high; however, qualitative studies have suggested that opioid users may use illicit buprenorphine to “self-treat” their opioid addiction, especially if they experience barriers to BMT. This study investigated illicit buprenorphine use among syringe exchange participants, a group with high needs for opioid addiction treatment, and explored whether illicit use was associated with access to BMT and interest in initiating BMT.

METHODS: Syringe exchange participants were recruited from the offices of a harm reduction agency in New York City. Computer-based interviews were conducted to determine: 1) prior use of buprenorphine (illicit and prescribed); 2) access to BMT (perceived barriers); and 3) interest in BMT (overall interest in BMT and likelihood of initiating treatment). Overall interest was measured using a 5-point Likert scale; those rating their level of interest as 4 or 5 were considered to be interested in BMT. Access to and interest in BMT were compared between illicit buprenorphine users and non-users using chi square or t-tests.

RESULTS: Of 102 opioid users, 57 had used illicit buprenorphine (34 with illicit buprenorphine use only; 23 with illicit and prescribed buprenorphine use). Nine participants had used prescribed buprenorphine only. Overall, 45 % of participants were interested in BMT. Regarding access, the most common barrier to BMT was, “did not know where to get treatment,” which was reported by 51 % of participants. Other common barriers were costs (33 %) and transportation (28 %). Compared to those who had never used illicit buprenorphine, not knowing where to get treatment was more common among illicit buprenorphine users (64 % vs. 36 %, $p<0.01$), overall interest in BMT was greater among illicit buprenorphine users (mean \pm SD; 3.37 ± 1.29 vs. 2.80 ± 1.34 , $p=0.03$), and more illicit buprenorphine users reported they would be likely to initiate BMT if it were easily accessible (82 % vs. 50 %, $p<0.01$).

CONCLUSIONS: Illicit buprenorphine use was common. A majority of illicit buprenorphine users were interested in BMT and reported that they would be likely to initiate treatment, but nearly two-thirds of illicit users did not know where to access BMT. Therefore, relatively simple interventions that address barriers to BMT (e.g. linking illicit buprenorphine users to practices that offer BMT or initiating BMT onsite at harm reduction agencies) could reduce illicit buprenorphine use, narrow the treatment gap, and diminish the tragic consequences of opioid addiction.

IMPACT OF A BEHAVIORAL ECONOMICS INTERVENTION ON CONTROL OF HYPERTENSION AMONG VERY POOR, PREDOMINANTLY MINORITY ADULTS: A RANDOMIZED TRIAL Martin F. Shapiro^{1,6}; Suzanne B. Shu²; Noah J. Goldstein^{2,3}; Craig R. Fox^{2,3}; Estival S. Villa¹; Martiniano Flores¹; Sitaram Vangala¹; Chi-Hong Tseng¹; Braden Mogler^{7,8}; Stewart B. Reed⁹; Ronald G. Victor^{4,5}; Jose J. Escarce^{1,6}. ¹UCLA, Los Angeles, CA; ²UCLA, Los Angeles, CA; ³UCLA, Los Angeles, CA; ⁴Cedars-Sinai Health System, Los Angeles, CA; ⁵Cedars-Sinai Health System, Los Angeles, CA; ⁶UCLA, Los Angeles, CA; ⁷UCLA, Los Angeles, CA; ⁸Charles R. Drew University of Medicine and Science, Los Angeles, CA; ⁹Columbia University, New York, NY. (*Tracking ID #1936163*)

BACKGROUND: Effective hypertension (HTN) control requires timely diagnosis, appropriate therapy, and long-term adherence. Poor HTN control contributes substantially to cardiovascular risk and racial/ethnic health disparities. We conducted a randomized trial of two interventions to improve blood pressure (BP) control among poor Latino and African American adults attending Federally Qualified Health Clinics in Los Angeles: provision of a home BP monitor and monthly BP checks to the control group, vs. provision of contingent payments and an “identity intervention” to the intervention group in addition to the control treatments.

METHODS: Consenting adults with BPs ≥ 149 mm systolic (SBP) and/or ≥ 94 mm diastolic (DBP) on two consecutive visits to the clinic, using a standardized measurement protocol, were randomized into control (CONT) or intervention (INT) conditions. Research staff did not interact with clinicians caring for subjects regarding BP control. Both groups were given educational materials on HTN and home BP monitors and training in their use. CONT received \$20 at each of months 1–6 if they returned for BP checks. INT were administered a survey to identify potential reasons to stay healthy or live longer (e.g. people in their lives, responsibilities to others, life goals and activities they enjoy) and were given personalized calendars with pictures of loved ones or representations of their activities/goals. They received \$10 at months 1–6 for returning, but an additional \$5 per item if they brought their calendar and BP monitor to a visit, and up to 3 lottery tickets at each visit (expected value: \$7 per ticket) if they 1) recorded HTN medication use on the calendar most days, 2) measured BP on most days, and 3) if BP was normal or improved from the previous visit. Finally, at each visit through 6 months, INT received contingent payments of \$2 per mm of SBP and DBP improvement up to normalization of BP (139/89), to a maximum of \$50 per visit; if BP was normalized, minimum payment was \$30. A research associate also spent time with INT at months 1–6 discussing what improved BP would

mean for their loved ones, goals, and activities. Both groups received \$20/visit for coming in for BP checks at 9 and 12 months. Summary statistics (mean, median, standard deviation and frequency distribution) were generated for demographic, social, behavioral and clinical characteristics. Repeated measurement analyses were carried out using logistic mixed effects models for the primary endpoints of change in control of SBP and DBP at 6 and 12 months.

RESULTS: Of 207 subjects randomized, 83 % completed 6 months follow-up and 75 % completed 12 months. Analyses including or excluding those lost to follow-up and with or without covariates other than baseline BP yielded similar results. Subjects were mean age 53.7 years, 51 % male, 59 % <12 years education, 21 % employed, 75 % household income <\$10,000, 64.8 % Latino and 33.2 % Black, 59 % born outside the US, 41 % diabetic, 69 % with ≥1 major chronic disease other than HTN; 41 % had recently gone without health care because they needed money for food, clothing or housing; 22 % had gone without food, clothing or housing because they needed money for health care. Experimental groups did not differ in these characteristics. Mean baseline BP was 162.3(SD 14.5)/91.6(14.2) mm in INT and 161.8(14.1)/88.7(12.8) mm in CONT. At 6 months, mean BP was 141.9(16.6)/81.1(13.9) mm in INT and 146.1(18.9)/80.4(15.0) mm in CONT. In multivariable analysis controlling for baseline BP, age, gender, education, race/ethnicity, born in US and diabetes, SBP control was achieved at 6 months in 57.1 % of INT and 40.2 % of CONT ($p=.033$). By 12 months, 39.5 % of INT and 35.0 % of CONT had normal range SBPs ($p=.729$). DBP fell by lesser amounts: nearly half were normal at baseline and over 70 % at 6 and 12 months. There was a trend toward greater DBP control at 6 months in intervention subjects ($p=.080$), but not at 12 months. At 6 months, INT improved relative to CONT in HTN medication adherence (Morisky Score) ($p=.027$) and in 2 measures of social support (someone to help with chores, and number of close friends with whom they felt at ease, both $p<.04$). Groups did not differ in patient activation scores. There was a trend toward more improvement in physical health (SF-12) in INT ($p=.058$).

CONCLUSIONS: We observed a 17 percentage point greater improvement in SBP control at 6 months in the group receiving contingent payments and the identity intervention compared to those receiving home BP monitors and monthly BP checks alone. This very encouraging result was not sustained once the intervention ended. Further research is needed to determine which component(s) of the intervention contribute to improvement, which characteristics predict benefit, and whether extending one or both interventions would sustain the improvement seen in this study, as well as to identify additional measures to further improve BP control in this highly disadvantaged population.

IMPACT OF CONFLICT OF INTEREST POLICIES ON PHYSICIAN PRESCRIBING OF ANTIPSYCHOTICS 2008–2011 Timothy Anderson¹; Haiden A. Huskamp²; Andrew Epstein³; Colleen Barry⁴; Aiju Men⁵; Ernst R. Berndt⁶; Marcela Horvitz-Lennon⁸; Sharon-Lise Normand^{2,7}; Julie M. Donohue⁵. ¹UPMC, Pittsburgh, PA; ²Harvard Medical School, Boston, MA; ³University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA; ⁴Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ⁵University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; ⁶MIT Sloan School of Management, Cambridge, MA; ⁷Harvard School of Public Health, Boston, MA; ⁸RAND Corporation, Pittsburgh, PA. (Tracking ID #1938503)

BACKGROUND: The impact of restrictive conflict of interest (COI) policies on physician prescribing behavior is poorly understood. It is unknown how academic prescribing trends compare with community settings where there has been less focus on regulating COI. We compared trends in physician prescribing of heavily promoted antipsychotic among physicians in academic medical centers and among physicians in two non-academic settings: a tightly regulated integrated delivery system with stringent COI policies and more loosely regulated community settings.

METHODS: We conducted difference-in-difference analyses of antipsychotic prescriptions filled in outpatient pharmacies between 2008 and 2011. We examined changes in prescribing of heavily promoted, new, and reformulated antipsychotics among 2,464 physicians in 101 academic medical centers stratified by exposure to COI policies compliant with American Association of Medical Colleges (AAMC) guidelines (defined as adopting 7 of 9 recommendations) as well as two comparison groups of 186 Kaiser Permanente physicians, and 11,201 community physicians.

RESULTS: 15 % of academic physicians were in AAMC compliant institutions throughout the study period, 23 % were in institutions that attained AAMC compliance, and 61 % were in institutions never reached compliance. The

shares of prescriptions for heavily promoted antipsychotics were no different across the academic, Kaiser, and community physician groups (range: 65–66 % in 2008 and 65–68 % in 2011). There were no statistically significant differences in the differences in the share of prescribing for heavily promoted antipsychotics over time across physician groups. Shares of prescriptions for new and reformulated antipsychotics more than doubled among academic physicians (from 2.4 to 6.2 % in AAMC compliant institutions, 2.9 % to 7.7 % in institutions attaining compliance, and 3.3 % to 7.0 % in non-compliant institutions). There were no statistically significant differences in the rate of increase between academic groups. In contrast, Kaiser physicians only increased their prescribing for heavily promoted and new antipsychotics from 1.7 % in 2008 to 2.6 % in 2011 for an increase that was 2 % lower than that of academic physicians in non-AAMC compliant institutions (95 % CI −0.04–0.00, $p=0.02$). Community physicians increased their prescribing of new and reformulated products from 4.6 % of antipsychotic prescriptions to 9.8 % from 2008 to 2011, for a change that was 2 % higher than academic physicians (95 % CI 0.01–0.02, $p<0.001$).

CONCLUSIONS: Prescribing of heavily promoted antipsychotics was virtually identical among academic physicians, and those practicing in an integrated health system and the community. However, there were differences in prescribing of new and reformulated antipsychotics across settings. The adoption of AAMC recommendations on physician-industry interactions appears to have had little impact on prescribing of a costly and widely used medication class.

IMPACT OF EMERGENCY DEPARTMENT COPAYMENTS IN MEDICAID
Mona Siddiqui; Craig E. Pollack. Johns Hopkins University School of Medicine, Arlington, VA. (Tracking ID #1939342)

BACKGROUND: The number of individuals enrolling in Medicaid has increased over the past several years due both to the recent recession which resulted in high levels of unemployment and the federal Deficit Reduction Act (DRA) of 2005 which enabled states to modify and expand the criteria for Medicaid eligibility. In an attempt to offer states more flexibility in administering their Medicaid programs while containing costs, the DRA allowed states discretion in instituting sliding scale premiums and copayments for Medicaid beneficiaries when accessing covered services. While some states had copayments for emergency department (ED) visits prior to 2005, the DRA granted states the ability to enforce cost-sharing. While prior studies show that cost-sharing can reduce health care utilization, the impact of the DRA on ED co-payments remains poorly understood. The objective of this study was to evaluate the impact of ED copayments on overall ED utilization among Medicaid beneficiaries following the DRA.

METHODS: We used the Medical Expenditure Panel Survey (MEPS), a nationally representative and longitudinal sample derived from the National Health Interview Survey, which oversamples African Americans and Hispanics. The study cohort consisted of individuals ages 19–64 who were on Medicaid. State linked data from 2001 to 2010 was used to compare ED use among patients in Washington, Florida, Minnesota, South Carolina, Kentucky, Ohio, Montana, Michigan and Pennsylvania that had instituted ED copayments during the study period against patients in Georgia, Virginia, Maryland, Louisiana, North Carolina, Connecticut, Tennessee, Colorado and Texas that had a zero copayment throughout. We used interrupted time series analysis with a Zero Inflated Poisson regression to assess differences between the pre-policy period (2001–2005) and the post-policy period (2007–2010), controlling for gender, race, age, education, marital status, income relative to federal poverty level, self-reported health and state fixed effects. Additional analyses examined changes in primary care office visits and inpatient length of stay.

RESULTS: The study cohort consisted of 3514 adult Medicaid recipients in states with copayments and 6766 adult Medicaid recipients in states with no copayments. Patients in states with copayments were significantly more likely ($p<0.01$) to be non-white, single, below the federal poverty level, and to have poor self-reported health. When controlling for these variables and state fixed effects, the study demonstrated that the enforcement authority of the DRA led to no significant differences in ED use in states with copayments when compared to states without copayments (OR: 1.06, 95 % CI: 0.94–1.18, $p>0.3$). Contrary to our expectations, office based provider visits decreased (OR: 0.90, 95 % CI: 0.88–0.92, $p<0.01$) and inpatient length of stay increased (OR: 1.19, 95 % CI: 1.12–1.27, $p<0.01$) in states with copayments when compared to zero copayment states.

CONCLUSIONS: The results of this study demonstrate no significant difference in ED utilization in states with copayments following the enforcement authority granted in the DRA. Although this policy has not impacted ED use, states continue to impose burdensome copayments on this vulnerable Medicaid population. States should consider other options to reduce ED utilization and promote primary care provider visits among Medicaid beneficiaries.

IMPACT OF EMR IMPLEMENTATION ON DIABETES PERFORMANCE MEASURES Catie Santana; Yuming Ning. Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY. (*Tracking ID #1933136*)

BACKGROUND: Montefiore Medical Center (MMC) is a large urban Accountable Care Organization in Bronx, NY with an integrated primary care network. Previous work demonstrated wide variation in diabetes performance measures by clinic type. Non-teaching sites with more Medicaid- or Medicare-insured patients (mixed payer) have the lowest performance, followed by mixed payer teaching sites, while non-teaching sites serving commercially-insured patients had the highest quality of care as measured by HEDIS measures. Although federal policy (e.g. Meaningful Use) incentivizes the implementation of electronic medical records (EMRs), the impact of EMRs on diabetes performance measures in previous studies has been mixed. We carried out this study to answer: (1) Did EMR implementation improve diabetes performance? and (2) Does EMR implementation impact different clinic types differently?

METHODS: We studied 20 sites during EMR implementation (2009–2011). We treated implementation as a natural stepped-wedge experiment since a group of clinics went ‘live’ with the EMR roughly every 4 months. Our performance measures included: HbA1c ≤ 8 %, LDL ≤ 100 mg/dL, BP ≤ 140/80, and microalbumin checked in the last 12 months. We queried our clinical database for the most recent value of each measure during each 4-month period, as well as the last baseline value in 2008 and the last post-EMR value in 2012. We restricted our analysis to patients who had a value documented during the baseline period and a value at least 8 months post-EMR to allow clinicians enough time to get acquainted with the EMR’s diabetes management features (e.g. reminders for missing labs). The stepped-wedge model included EMR status (yes/no) during each time period for the site where each patient belongs as the main independent variable and a time period variable. We adjusted for baseline patient-level value, and patient-level age, sex, race/ethnicity, insurance. The clinic was included as a random effect.

RESULTS: Our sample included 8,375–16,202 patients depending on the measure. EMR implementation was not associated with a significant change in performance. The odds of post-EMR measures meeting the nationally accepted benchmarks compared to pre-EMR were: 0.94 for HbA1c control ($p=0.13$), 1.03 for LDL control ($p=0.47$), 0.93 for BP control ($p=0.13$), and 0.97 for microalbumin checks ($p=0.54$). One clinic (Commercial) significantly improved in A1c and LDL control (OR 1.17, ($p=0.01$) and OR 1.12 ($p=0.01$), respectively). Five clinics improved in BP control while 4 had significantly worse control including the Commercial site that improved in A1c and LDL. All three site types were represented among both groups. There were no sites that significantly changed in microalbumin checks compared to their pre-EMR performance.

CONCLUSIONS: We found no association between EMR implementation and a change in diabetes care as measured by nationally endorsed performance measures. We also did not find a pattern where certain site types were more likely to change in performance post-EMR than other site types. Given the baseline heterogeneity by teaching status and payer mix among our sites, we had hypothesized that the EMR could serve as a large resource investment that could help equalize performance. However, the implementation of a Meaningful Use-compliant EMR did not result in a significant improvement in diabetes control. Although there might be other benefits from the EMR not captured in these performance measures, our network must look to other interventions that may improve the effectiveness of diabetes care.

IMPACT OF GEOGRAPHIC ROUNDING AND MULTI-DISCIPLINARY ROUNDS ON COORDINATION OF CARE AND DISCHARGE TIMES Cathryn Caton; Kristin R. Wise; Rogers Kyle; Kim Curnell-Pean; Patty J. Iverson. Medical University of South Carolina, Charleston, SC. (*Tracking ID #1915824*)

BACKGROUND: Initial studies demonstrate that locating the majority of a physician’s patients on a designated unit (geographic rounding) can enhance physician efficiency and facilitate physician nurse communication. Further benefits can include better patient satisfaction, improved patient outcomes and streamlined hospital throughput. Literature also supports the use of multi-disciplinary rounds to improve coordination of care and teamwork. We sought to evaluate the effects of geographic rounding for hospitalists’ patients and multi-disciplinary rounds on coordination of care and discharge times at our academic medical center.

METHODS: At our institution, we implemented geographic rounding for two non-teaching hospitalist teams (PHS) on a designated unit of the main hospital. We determined that 80 % of all PHS patients should be located on this unit. We initiated multi-disciplinary rounds to include hospitalists, nurses, case managers, physical and occupational therapists with a goal of increasing patient discharges prior to 3 pm. On a monthly basis, we tracked every aspect of the discharge process from the time orders were written to the time patients left the hospital. These discharge times were compared to those prior to project initiation. Physicians and nurses assigned to the designated unit completed a validated survey to assess their perceptions of care decisions before and 5 months after geographic rounding began.

RESULTS: Initial and repeat survey response of physicians and nurses were similar - 98 % and 93 % respectively. Of respondents, 83 % were female, 55 % were nurses and the majority was between ages 29–46. Fifty percent had community based practice experience. Matched analysis was performed on survey data finding improvements in 5 of 6 domains ($p<0.05$). Respondents agreed that there was better communication and coordination between physicians and nurses about patient care decisions and plans. The percentage of patient discharges prior to 3 pm increased from 15 to 54 %.

CONCLUSIONS: The initiation of geographic rounding and multi-disciplinary rounds increased communication and coordination of patient care between physicians and nurses. With the implementation of both initiatives, we increased the percentage of patients discharged prior to 3 pm.

IMPACT OF HEALTH COACHING ON PATIENT TRUST IN THEIR PRIMARY CARE PROVIDER: A RANDOMIZED CONTROLLED TRIAL David Thom; Danielle Hessler; Rachel Willard-Grace; Thomas Bodenheimer; Adriana Najmabadi; Christina Araujo; Ellen Chen. UCSF, San Francisco, CA. (*Tracking ID #1928972*)

BACKGROUND: In primary care, there has been a move to share tasks and responsibilities traditionally reserved for the primary care provider (PCP) with other members of the patient care team, including medical assistants, nurses, pharmacists, patient educators and coaches. Concern has been raised regarding the impact of the ‘team approach’ on the quality of the patient-provider relationship. We analyzed data from a randomized controlled trial comparing health coaching to usual care to assess the impact of health coaching on patients’ relationship with their primary care provider (PCP).

METHODS: Randomized controlled trial comparing health coaching with usual care. Participants were low-income English or Spanish speaking patients age 18 to 75 with poorly controlled type 2 diabetes, hypertension and/or hyperlipidemia. Health coaches were certified medical assistants who attended 40 h of health coach training over 6 weeks using a curriculum developed by the study team that included instruction in using active listening and non-judgmental communication; helping with self-management skills including creation of action plans, and providing social and emotional support. Patient trust in their primary care provider measured by the 11-item Trust in Physician Scale, converted to a 0 to 100 scale. Patient satisfaction with their PCP was assessed by a single item, “How likely would you be to recommend your doctor to your friend or relative?” with a response scale from 1 = ‘definitely not recommend’ to 5 = ‘definitely recommend’. Data were analyzed using linear mixed modeling. P-values were two-tailed.

RESULTS: A total of 441 patients were randomized to receive 12 months of health coaching ($n=224$) vs. usual care ($n=217$). At baseline, there were no significant differences in participant characteristics between the two study arms, including trust in their PCP (Table 1). At 12 months, trust and satisfaction were reported by 203

patients (91 %) in the health coaching group and 175 of patients (81 %) in the usual care group. Both the mean level of patients' trust in their PCP and the percent of patients who would definitely recommend their primary care provider to family or friends increased significantly more in patients receiving health coaching (Table 2). These differences remained significant after adjustment for number of PCP visits during the study.

CONCLUSIONS: Health coaching does not appear to lower, and in fact may increase, patients' trust in their primary care providers. Clinicians should be reassured that working with health coaches does not appear to compromise, and may in fact enhance, their relationships with their patients.

Table 1. Participant characteristics at enrollment by study arm (% or mean (sd))*

Characteristic	Health coaching arm (n=224)	Usual care arm (n=217)
Age (years)	52.6 (10.7)	52.9 (11.5)
Gender (female)	52 %	59 %
Born in the US	26 %	25 %
Years living in US**	18.5 (10.4)	17.9 (11.9)
Spanish is primary language	68 %	70 %
Race/Ethnicity:		
African American	20 %	18 %
Latino or Hispanic	69 %	71 %
White non-Hispanic/Asian/Other	11 %	11 %
Education less than high school	44 %	44 %
Annual household income <\$10,000	60 %	56 %
Trust score	72.4 (12.4)	72.7 (12.7)
Would definitely recommend PCP	57 %	59 %

* There were no statistically significant differences by study arm. ** For participants born outside the United States

Table 2. Change in patient trust in and satisfactions with the primary care provider (PCP) and number of visits to the PCP from baseline to 12 months

Outcome	Change in health coach group	Change in usual care group	Difference in change	95 % CI	p-value	Adjusted p-value
Patient Trust score (mean)	+ 3.8	+1.4	2.4	0.03 to 4.8	.047	.033*
Definitely recommend PCP (%)	+16.3 %	+4.0 %	12.3 %	5 % to 24 %	.002	.015*

*Adjusted for number of visits to PCP during 12 month intervention.

IMPACT OF HIGH-DEDUCTIBLE HEALTH PLANS ON DIABETES MONITORING AND OUTCOMES James F. Wharam; Fang Zhang; Emma Eggleston; Steve Soumerai; Dennis Ross-Degnan. Harvard Medical School, Boston, MA. (Tracking ID #1939979)

BACKGROUND: The Affordable Care Act is expected to dramatically increase high-deductible health plan enrollment. Hemoglobin A1C monitoring improves diabetes outcomes but the expansion of high-deductible health insurance could reduce secondary preventive care. No studies have examined the impact of high-deductible health plans on intermediate outcomes such as diabetes control.

METHODS: We studied administrative claims representing 13,974 baseline person years of patients with diabetes. Members were continuously enrolled for 2 years through a large national insurer between 2004 and 2012. To minimize selection bias,

we included members who could choose only one health plan in their follow-up year. We analyzed monthly hemoglobin A1C testing rates for 1 year before and after subjects' employers mandated a switch from traditional low-cost-sharing plans to high deductible plans, compared with rates among a contemporaneous 2:1 propensity score matched control cohort. We also examined mean monthly hemoglobin A1C values among a subset of members with laboratory value data. We subtracted monthly measurement rates of the control group from those of the HDHP group to obtain a before-after difference trend, then used an autoregressive correlation structure in a generalized least squares model containing the covariates of time in months, an indicator for follow-up versus baseline period, and time in months in the follow-up period. We included all covariates in the model regardless of statistical significance.

RESULTS: Hemoglobin A1C testing rates in the high deductible group relative to the control group did not change significantly from the baseline to the follow-up year (level and trend changes of -0.0005 in month 13, [95 % C.I., -0.0040 to 0.0031] and 0.0001 per month, [-0.0004 to 0.0007], respectively, Figure 1). Hemoglobin A1C levels also did not change (level and trend changes of 0.038, [-0.146 to 0.222] and 0.000, [-0.027 to 0.026], Figure 2).

CONCLUSIONS: Switching from traditional health plans to high-deductible health plans did not change hemoglobin A1C testing or levels after 1 year. Initial results might be reassuring to policymakers overseeing the expansion of high-deductible health insurance, but our pending analyses will examine 3 follow-up years as well as key subgroups such as the poor and sick.

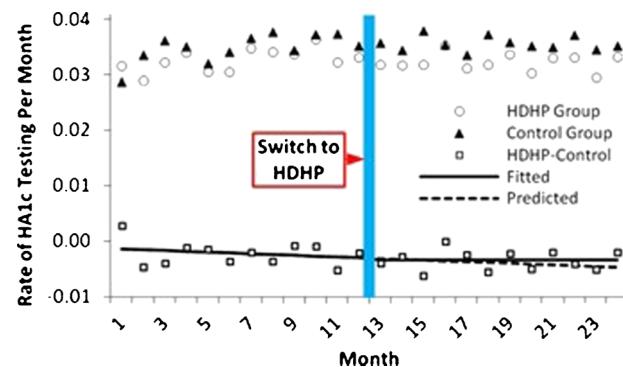

Figure 1. Monthly rates of hemoglobin A1C testing before and after transition to high-deductible insurance.

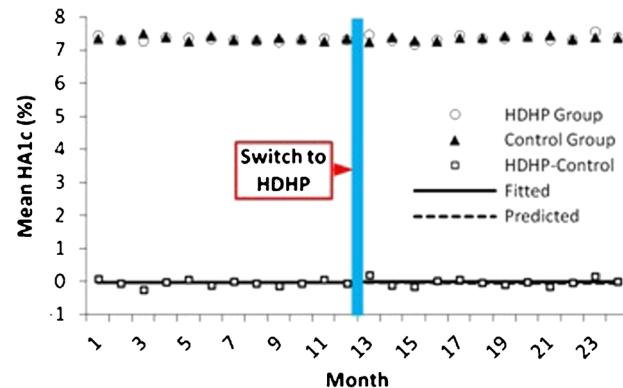

Figure 2. Monthly hemoglobin A1C values before and after transition to high-deductible insurance.

IMPACT OF HOSPITALIST WORKLOAD ON PATIENT OUTCOMES: AN ANALYSIS OF 2 ACADEMIC MEDICAL CENTERS Henry J. Michalik^{1,2}; Nowella Durkin³; Eric Howell^{2,4}; Amy Deutschendorf³; Jason D. Miller³; Daniel Brotman^{1,3}. ¹Johns Hopkins University School of Medicine, Baltimore, MD; ²Armstrong Institute for Patient Safety and Quality, Baltimore, MD; ³Johns Hopkins Hospital, Baltimore, MD; ⁴Johns Hopkins Bayview Medical Center, Baltimore, MD. (*Tracking ID #1931177*)

BACKGROUND: Front-line hospitalists report that excessive hospitalist workload adversely affects quality of patient care. However, there is a paucity of research examining the direct impact of variation in workload on patient outcomes. We determined the association between individual hospitalist workload at 2 academic medical centers and length of stay, readmission, and hospital-acquired conditions.

METHODS: Using administrative and billing data for standard daytime shifts, we examined all non-observation inpatient admissions to the hospitalist service for fiscal year 2013 at 2 academic medical centers. One site has a fixed hospitalist unit of 17 beds and the other site maintains a census cap of 12 patients per hospitalist. We defined daily hospitalist workload as the number of patient encounters billed by each hospitalist on a given day. For each patient admitted, we then calculated the average workload of all treating hospitalist providers during the respective patient's entire hospital course. For example, a patient hospitalized for 2 days and cared for by a hospitalist who saw 8 patients on Day 1 and another hospitalist who saw 12 patients on Day 2 would have an average hospitalist workload of 10. We determined the association between average provider workload and odds of exceeding the expected length of stay, having a 30-day all-cause readmission, and developing a Maryland hospital-acquired condition. Using multiple logistic regression, we adjusted for patient demographics (age, race, sex), severity of illness (All Patient Refined Diagnosis Related Group Severity of Illness score; range 1–4), observed length of stay, percentage of weekdays, number of treating hospitalists, and hospital site.

RESULTS: There were 5068 inpatient admissions from July 2012 to June 2013. The average hospitalist workload was 7.7 (SD±2.2) encounters per day, and patients were treated by 2 different hospitalists [IQR: 1, 3]. Patients had a median age of 60 years [IQR: 49, 74] and severity of illness score of 2 [IQR: 2, 3]. Sixty-two percent of patients were Caucasian and 54 % were female. Median length of stay was 3 days [IQR: 2, 5] and on average, weekdays accounted for 80 % of the hospitalization. The readmission rate was 15.5 % and 137 patients developed at least one hospital-acquired condition. Average hospitalist workload was not a statistically significant predictor for exceeding the expected length of stay, being readmitted, or developing a hospital-acquired condition. Hospitalizations exceeding the expected length of stay occurred with lower patient severity of illness and percentage of weekdays, and increased length of stay (all $p < 0.01$). For readmissions, only age (OR: 0.92 per 10 additional years; 95 % CI: 0.88, 0.96) and severity of illness (OR: 1.44 per category increase; 95 % CI: 1.29, 1.61) were significant predictors. For hospital-acquired conditions, severity of illness (OR: 2.86; 95 % CI: 2.15, 3.81) and length of stay (OR: 1.07 per additional day; 95 % CI: 1.04, 1.09) significantly increased the odds of occurrence.

CONCLUSIONS: When hospitalist workload was measured across the entire patient hospitalization, variation in workload did not impact length of stay, readmission, and hospital-acquired conditions; only severity of illness was a consistent statistically significant predictor of these outcomes. Our results suggest that in the setting of workload control strategies (fixed number of hospitalist beds, census caps), workload variation may not be associated with worsened patient outcomes. Larger studies with greater variation in workload at the individual physician level and higher patient volumes are needed to better understand workload's potential impact on patient outcomes. Multi-center, randomized-controlled studies may also determine the effectiveness of different workload control strategies in managing workload variation, facilitating patient flow, and optimizing patient outcomes.

IMPACT OF INTRODUCTION OF ABUSE-DETERRENT OXYCONTIN ON OPIOID OVERDOSE RATES Marc Larochele; Fang Zhang; Dennis Ross-Degnan; James F. Wharam. Harvard Medical School, Boston, MA. (*Tracking ID #1937010*)

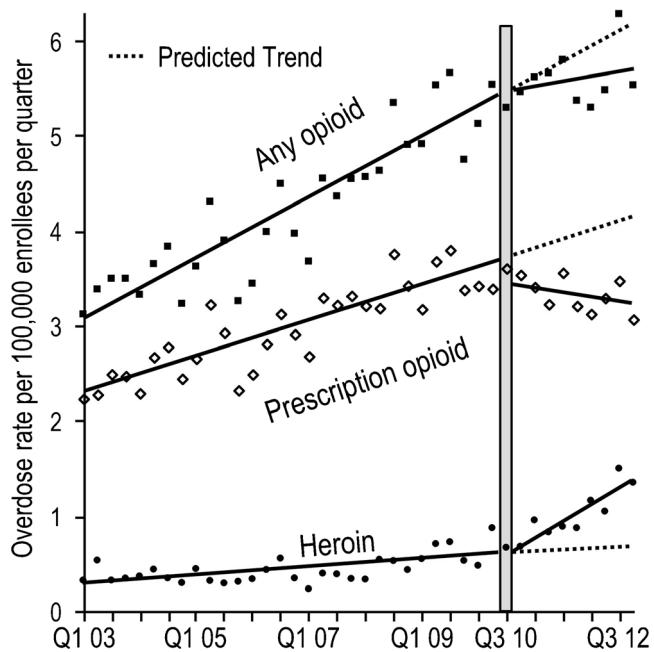

BACKGROUND: Opioid overdose and overdose deaths are increasing in the United States. An abuse-deterring formulation of OxyContin, a frequently abused opioid, was introduced in August 2010. Reports from opioid abusers suggest a decreased preference for OxyContin and increased preference for heroin following the formulation change; however, the impact on overdose rates is unknown.

METHODS: We analyzed an open cohort of commercially insured enrollees aged 18–64 years from a large national United States health insurer claims database. We used an interrupted time series design to analyze quarterly outcomes from 2003 to

2012 divided into three periods: pre formulation change, Q1 2003–Q2 2010; formulation change phase-in period, Q3 2010; and, post formulation change, Q4 2010–Q4 2012. Outcomes were rates of overdose due to any opioid, overdose due to a prescription opioid, and heroin overdose. We identified overdose from inpatient or emergency department claims with ICD-9 diagnosis codes for opioid poisoning. We standardized rates to gender, age, region, and race of Q2 2010 enrollees. We used segmented linear-regression to: a) predict expected post formulation change overdose rates based on Q1 2003–Q2 2010 trends; and b) model the observed Q4 2010–Q4 2012 trend. We used multivariate delta methods to estimate the effect of the formulation change at 2 years.

RESULTS: We analyzed claims for 31.3 million enrollees with a median enrollment of 17 months and 13,654 opioid overdoses from 2003 to 2012. Two years following introduction of abuse-deterring OxyContin, the observed overall overdose rate was an estimated 5.7 per 100,000 enrollees per quarter, lower than the predicted rate of 6.1 per 100,000 enrollees per quarter (relative change –7.2 %; 95 % CI, –13 % to –1.9 %). The estimated overdose rate due to prescription opioids decreased from an expected 4.1 to 3.2 per 100,000 enrollees per quarter (relative change –21 %; 95 % CI, –25 % to –16 %). However, the estimated heroin overdose rate increased from an expected 0.7 to 1.3 per 100,000 enrollees per quarter (relative change +91 %; 95 % CI, 53 % to 130 %; Figure).

CONCLUSIONS: Two years after introduction of abuse-deterring OxyContin, overall opioid overdose decreased to a small degree, but heroin overdose nearly doubled. Substitution of alternative opioids may limit the effectiveness of abuse-deterring formulations on the opioid overdose epidemic.

Age, gender, region, and race standardized rates of opioid overdose before and after introduction of abuse-deterring OxyContin.

IMPACT OF LOSS OF INTERPERSONAL CONTINUITY ON PATIENT EXPERIENCE OF CARE AND AMBULATORY QUALITY OF CARE Ashok Reddy^{1,4}; David A. Asch^{2,3}; Anne Canamucio²; Rachel M. Werner^{2,3}. ¹University of Pennsylvania, Philadelphia, PA; ²VISN 4 Center for Evaluation of PACT, Philadelphia, PA; ³Leonard Davis Institute of Health Economics, University of Pennsylvania, Philadelphia, PA; ⁴Robert Wood Johnson Clinical Scholar Program, University of Pennsylvania, Philadelphia, PA. (*Tracking ID #1938406*)

BACKGROUND: Continuity remains a core tenet of primary care. Several studies link a more continuous PCP-patient relationship with higher patient satisfaction, higher preventive service use, and lower hospitalizations rates. Continuity is often defined as having three components: interpersonal (having a continuous personal physician-patient relationship), longitudinal (having a medical home in which patients

receive the majority of their care), and informational (having a patient's medical records available at the time a doctor sees the patient). While prior work demonstrates the importance of continuity on patient care outcomes, it is uncertain which component of continuity matters most. Our study focuses on isolating the impact of interpersonal continuity in the setting of stable informational and longitudinal continuity. In the setting of the Veterans Health Administration (VHA), we conduct an analysis of patients who experienced a loss of the interpersonal relationship (primary care provider turnover) but continue to receive care at the VHA (stable longitudinal and informational continuity). We then measure the impact of turnover on patient care experience and ambulatory quality of care.

METHODS: We included all patients enrolled in primary care at the Veterans Health Administration (VHA) between 2010 and 2012 who were also included in one of two national datasets used to measure our outcome variables: the Survey of Healthcare Experiences of Patients (SHEP; used to measure patient experience of care) and the External Peer Review Program (EPRP; used to measure ambulatory quality of care). Both datasets include a random sample of veterans receiving outpatient care in the VHA. We measured primary care provider (PCP) turnover in the 2 years prior to measuring patient experience and quality of care using VHA primary care encounter data. A linear probability model was used to test whether PCP turnover was associated with changes in patient experience of care and ambulatory quality of care, adjusting for patient-level covariates (age, gender, race, income and DCG risk score) and clinic-level fixed effects, and clustering standard errors at clinic level.

RESULTS: Our analyses include SHEP responses from 639,011 patients (9 % of who experience PCP turnover) and EPRP data from 361,627 patients (10 % experiencing PCP turnover). A majority of respondents reported positive experiences of care in 3 out of 5 domains: How well doctor/nurse communicate (53 %), rating of personal doctor/nurse (71 %), and overall rating of VHA healthcare (59 %). In addition, patients had high rates of completion of testing for retinal preventive care (90 %), control of hypertension (79 %) and colon cancer screening (82 %). In our primary analysis, PCP turnover was associated with a decrease in all 5 domains of patient care experience. For example, PCP turnover was associated with a 3.7 percentage point ($p < 0.05$) lower response in how well a patient communicates with his or her provider. However, we found no association between PCP turnover and ambulatory quality of care measures.

CONCLUSIONS: With increasing primary care turnover, interpersonal continuity in medical care continues to diminish. Our study shows that loss of interpersonal continuity is a common experience and is associated with a small but significantly worse patient experience of care. However, this loss of interpersonal continuity does not impact the quality of preventive services for common ambulatory conditions. These findings demonstrate that health care systems with robust informational and longitudinal continuity could mitigate the impact of a loss of any one provider on a person's healthcare.

IMPACT OF MEDICAID INELIGIBILITY FOR INCARCERATED INDIVIDUALS ON INSURANCE EXPANSION UNDER THE AFFORDABLE CARE ACT: A BLIND SPOT OF REFORM

Elisabeth Poorman¹; Anne Spaulding².
¹Cambridge Health Alliance, Cambridge, MA; ²Rollins School of Public Health, Atlanta, GA. (Tracking ID #1939132)

BACKGROUND: The Patient Protection and Affordable Care Act (ACA) aimed to expand Medicaid coverage to individuals with incomes below 138 % of the federal poverty level. However, inmates of prisons and jails, many of whom have low incomes and high levels of disease burden, have been prohibited from receiving Medicaid since its inception. When previous recipients of Medicaid are freed, they typically have a long lag time before re-enrollment. This prevents connection to care during the early post-release period, a time which has been demonstrated to have high mortality. Little is known about the impact of making incarcerated individuals temporarily ineligible for Medicaid, or what the impact will be on the success of Medicaid expansion.

METHODS: Using the most recently available national surveys of prison and jail inmates from the Bureau of Justice Statistics, this study calculates the expected number of admissions to US prisons and jails in 2014 and the number of these that would have been eligible for Medicaid under the ACA had they not been incarcerated. Using estimates for the number of Americans age 18–64 who will qualify for Medicaid under the ACA in 2014 from the Kaiser Family Foundation, we calculate the percentage of all individuals that would otherwise qualify for Medicaid who will spend part of 2014 in jail or prison.

RESULTS: The total number of adults in prison at year's end in 2011 was 1,598,780. Adding the total released, subtracting the number of those released predicted to recidivate in 1 year, assuming incarceration rates remain static, we estimate that 2.2 million people will be imprisoned in 2014. Discounting new admissions, most of whom pass through jail, we calculate 1.5 million people who will spend part of the year in prison but not jail. One in three prisoners reports a pre-arrest monthly income

below 138 % of the poverty line, and slightly more than 98 % of this population is between the ages of 18 and 65. Therefore, 491,300 prisoners would have been eligible for Medicaid in 2014. The number of unique yearly admissions to jail is calculated to be 8.28 million, derived from total admissions (11.6 million in 2012) divided by 1.4 average admissions per person. Close to 99 % of jail inmates are between 18 and 65, and approximately two out of three jail inmates report a monthly income below 138 % of the poverty level, resulting in 5.1 million jail inmates who would be Medicaid eligible. According to the Kaiser Family Foundation, the total number of people between 18 and 65 below 139 % of the poverty level is close to 87 million. We therefore calculate that 7.6 %, or one in thirteen people, who meet income eligibility for Medicaid under the Affordable Care Act will be incarcerated in 2014.

CONCLUSIONS: A substantial number of low income individuals will fail to benefit from the Medicaid expansion under the ACA due to the ban on Medicaid coverage for inmates of prisons and jails. Pro-actively enrolling this population upon release is key to ensuring that large numbers of poor Americans are connected to care at a time when they are most vulnerable.

IMPACT OF OBESITY ON HEART RATE RESPONSE DURING TREADMILL EXERCISE

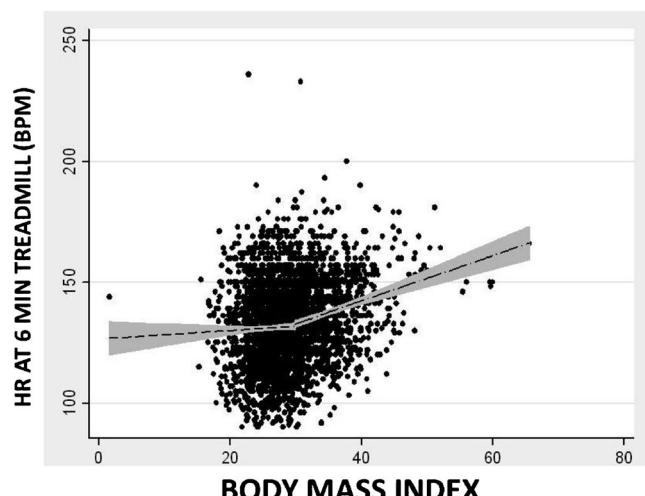

Cindy Wang; Daniel Spevack. Montefiore Medical Center, Bronx, NY. (Tracking ID #1939767)

BACKGROUND: Prior works have found attenuated exercise heart rate response in obese subjects. These studies, however, have compared subjects in terms of peak heart rate achieved. We aimed to compare the exercise heart rate response between obese and non-obese subjects in terms of the heart rate achieved at a fixed level of exercise.

METHODS: Echocardiography reports were reviewed from 4,497 patients referred for treadmill maximal exercise testing using the Bruce protocol between 1/1/2010 and 6/30/2012. Patients were excluded if they had resting HR>90 bpm ($n=421$), performed <6 min of exercise ($n=809$), abnormal left ventricular wall motion either before ($n=47$) or after ($n=145$) exercise. Heart rate response was compared between subjects using the heart rate achieved at 6 min into the Bruce protocol.

RESULTS: The 3,075 patients in the study group were 52±12 years, 56 % female, BMI 29 ±6, resting HR 70±10 bpm and resting BP 141±19 mmHg. Patients exercised for 8.9±2 min, achieving HR 133±19 bpm at 6 min and 158±19 bpm at peak. Peak BP was 160±23 mmHg. At 6 min exercise, HR change from rest was greater in the obese group (66±17 vs 61±19 bpm, $p < 0.001$). Obese subjects exercised for shorter duration (8.4±8 vs 9.3±2 min, $p < 0.001$), but had no difference in the maximum HR achieved compared to non-obese subjects (158±17 vs 157±20, $p = 0.2$). While BMI directly correlated with HR achieved at 6 min in obese subjects (beta 0.94, $p < 0.001$), this was not the case in non-obese subjects (beta 0.19, $p = 0.2$). Figure. Using multiple linear regression, increased age (beta -0.08), female sex (beta -0.94), body mass index (beta -0.09) and HR at 6 min (beta -0.04) were each independently associated ($p < 0.001$ for all) with reduced maximal exercise duration.

CONCLUSIONS: Obesity is associated with accelerated heart rate response with exercise. Obesity and HR achieved at 6 min of Bruce protocol were independent predictors of reduced exercise capacity.

The Relationship Between Heart Rate and Body Max Index at Six Minutes of Treadmill Exercise Stress Testing

IMPACT OF THE AFFORDABLE CARE ACT ON PATIENTS' OUT-OF-POCKET BURDEN Kevin Riggs^{1,2}; Christine Butorff³; G. Caleb Alexander^{1,3}. ¹Johns Hopkins University School of Medicine, Baltimore, MD; ²Johns Hopkins Berman Institute of Bioethics, Baltimore, MD; ³Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (*Tracking ID #1931572*)

BACKGROUND: Out-of-pocket (OOP) spending caps under the Patient Protection and Affordable Care Act (PPACA) are designed to limit the financial toll of high health care costs for individuals and their families. Individuals and families who obtain private insurance outside of health insurance exchanges will have uniform OOP caps, equal to the cap for Health Savings Account qualified plans (\$6350 for individuals and \$12,700 for families for 2014). In contrast, OOP caps are income-based for those who purchase private insurance through health care exchanges, such that patients with lower incomes have lower OOP caps. The goal of this study was to estimate the proportion of Americans who have OOP costs greater than the OOP spending caps.

METHODS: We used the 2011 Medical Expenditure Panel Survey, a large nationally representative longitudinal panel survey designed by the National Center for Health Statistics, to examine OOP costs for medical care and prescription drug utilization. We limited our analyses to adults age 18–64 with private health insurance. The primary outcome was the proportion of individuals whose spending exceeded the uniform OOP cap for insurance purchased outside of health insurance exchanges. To examine the effect of OOP caps for individuals with varying incomes, we categorized individuals' incomes relative to the federal poverty limit (FPL). We then estimated the proportion of individuals who would exceed OOP caps under the hypothetical scenario where the income-based OOP caps available through the exchanges are applied to everyone with private insurance. Costs were inflated to 2014 dollars. Lastly, we examined how self-reported cost-related access problems (unable to obtain medical care or prescription drugs for reasons "could not afford" or "insurance would not cover") varied by OOP costs.

RESULTS: There were 12301 insured adults in the survey, representing a weighted population of over 136 million individuals. Median household income was \$77,755. The proportion of individuals with OOP costs greater than the uniform cap was 0.93 %, and the proportion exceeding the cap decreased with increasing family income (2.10 % of those <100 % of FPL, and 0.84 % of those >400 % of FPL). Applying the income-based caps (and assuming those <100 % FPL would be granted a reduced cap, which they would not actually be able to obtain through the exchange), the proportion with OOP costs greater than the cap was 2.29 %. Specifically, 3.75 times as many individuals <400 % FPL would benefit from the income-based caps, compared with the uniform caps. Self-reported cost-related access problems was low (1.99 % overall), although there was an inverse gradient, with problems decreasing as income increased (5.21 % for <100 % FPL and 1.02 % for >400 % FPL).

CONCLUSIONS: Individuals with lower income experience greater self-reported cost-related access problems, and they are more likely to have high OOP costs. The uniform OOP spending caps under PPACA will impact a modest proportion of individuals, with those in the lowest income categories most likely to benefit. However, extending the income-based spending caps to include insurance purchased outside of the exchanges would have a much larger impact.

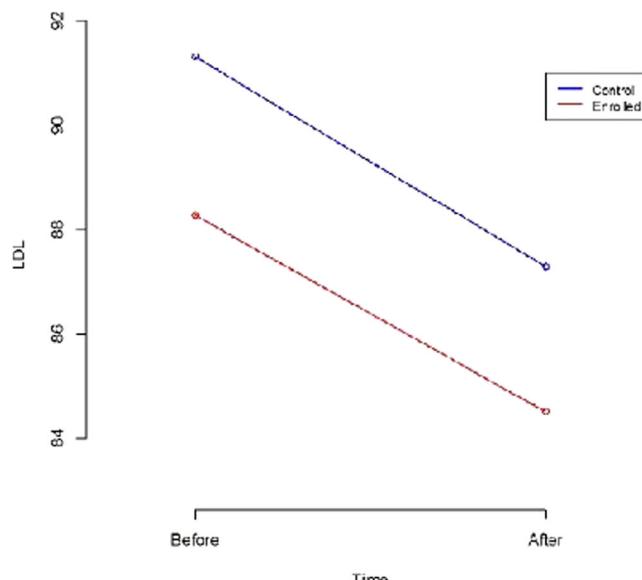

IMPACT OF VA HEALTH INFORMATION EXCHANGE UPON THE QUALITY OF DIABETES CARE David Haggstrom^{1,2}; Laura J. Myers^{1,2}; Dustin D. French³; Jeff Barnd¹; Marc Roseman⁴; Joseph Kesterson⁵; Alan Zillich^{1,7}; Deming Mi⁶; Susan Perkins⁶. ¹VA Health Services Research and Development, Indianapolis, IN; ²Indiana University School of Medicine, Indianapolis, IN; ³VA Health Services Research and Development, Hines, IL; ⁴Indiana University School of Medicine, Indianapolis, IN; ⁵Regenstrief Institute, Indianapolis, IN; ⁶Indiana University School of Medicine, Indianapolis, IN; ⁷Purdue University, Indianapolis, IN. (*Tracking ID #1931393*)

BACKGROUND: Like most health care systems, the VA often has patients who receive some portion of their care outside the VA. Due to the lack of interoperability among electronic health record systems, providers caring for veterans who are receiving services outside the VA may not have timely access to important information about their patients. Health information exchange (HIE) advocates believe that greater interoperability will improve the quality of care. In this study, measures of ambulatory care quality were chosen that an expert panel suggests may be sensitive to the effect of HIE, and feasible for electronic data capture.

METHODS: Intervention: A regional VA-HIE demonstration program was conducted through a national initiative called the Virtual Lifetime Electronic Record (VLER). The VA-HIE performed secure, bi-directional health information exchange between the VA and community partners organized together through the Indiana Network for Patient Care. Health care providers inside and outside the VA were able to access exchanged data. Patients were enrolled in the VA-HIE program on-site at the Indianapolis VA in outpatient clinics or through the release-of-information office. Study design: A pre-post cohort evaluation of the VA-HIE program was performed, with a concurrent control group. For the evaluation, data on care received by patients inside and outside the VA were obtained for 1 year before, and 1 year after, the index date of patient enrollment. To allow for program implementation lag time and enable providers to become accustomed to using HIE data, the first study patients were enrolled in the cohort 3 months after VA-HIE implementation. All control patients were enrolled 3 months after VA-HIE implementation. Population: Patients with diabetes (at least 2 diagnoses) were included in the evaluation. Patients were included if they had at least 1 clinical encounter at the Indianapolis VA over a 1-year period prior to the index date. Overall, 9,612 patients diagnosed with diabetes were followed: 1,768 enrolled in the VA-HIE intervention and 7,844 in the control group. Measures/Analyses: For hemoglobin A1c (HgA1c), both the mean lab values and the proportion of diabetics with HgA1c <9 % were measured. For LDL, the mean lab values, and the proportions of diabetics with LDL<130 and LDL<100 were measured. Multivariable regression models were constructed as a function of VA-HIE intervention status, time, and baseline covariates (race/ethnicity, insurance, marital status, Charlson comorbidity index, and service-connected disability).

RESULTS: The mean age (62.4 years) and race (27 % non-white) were no different between intervention and control groups. However, there were statistically significant differences between the VA-HIE intervention and control groups in the proportion insured (66 % vs. 64 %), married (63 % vs. 58 %), comorbidity index (0.62 vs. 0.39) and with service-connected disability (85 % vs. 82 %). The sources of the diabetes diagnostic information were the VA (80 %), community partners (3 %), or both (16 %) electronic data systems. Among the diabetes population, the VA-HIE had no significant effect over time on the mean HgA1c value or the proportion of patients with HgA1c <9 %. For all of the LDL measures, there were significant effects of both the VA-HIE intervention and time (Figure 1), but the interaction effect was not significant.

CONCLUSIONS: Providers of patients enrolled in the VA-HIE had better access to data residing in non-VA health care systems. About 1 in 5 veteran patients had data identifying diabetes diagnoses in non-VA electronic data systems. The VA-HIE program had no measureable effect upon the quality of diabetes care. Possible reasons for the lack of effect may be that HIE does not influence these types of care management processes, the amount of data shared with the VA was not sufficient to affect care quality, or the evaluation was performed early in the implementation or diffusion of the VA-HIE.

Adjusted means of LDL for fitted regression model

IMPLEMENTATION OF A TRIAGE-STAFF INITIATED ROUTINE HIV SCREENING PROGRAM IN AN INNER CITY PRIMARY CARE CENTER IN A HIGH HIV PREVALENCE AREA Natasha Travis; Jennifer Spicer; Heather Freiman. Emory University, Atlanta, GA. (*Tracking ID #1938815*)

BACKGROUND: Both the U.S. Centers for Disease Control and Prevention (CDC) and the U.S. Preventive Services Task Force (USPSTF) have issued recommendations for routine HIV testing for individuals 13–64 years of age in all healthcare settings in the United States. However, many primary care centers (PCCs) still have not implemented routine HIV screening. The objective of this analysis is to describe the implementation of a routine HIV screening program in a PCC in a high HIV prevalence area.

METHODS: In July 2013, a routine triage-staff initiated HIV screening program was instituted in the PCC of an inner-city safety-net hospital in a high HIV prevalence area. Triage staff, comprising nurses and medical assistants, was instructed to complete HIV screening for all eligible PCC patients using an electronic medical record based HIV Screening Tool. Patients were eligible to receive a test offer if they were: at least 18 years old, capable of consent, and did not have HIV test results in the last 6 months. Eligible patients were offered an HIV test using opt-out language. If the patient did not opt-out, an HIV test was ordered by the triage staff and the patient was instructed to go to the outpatient laboratory for the test. A retrospective chart review was performed to assess initiation of the Screening Tool and HIV test offer, uptake, and completion rates.

RESULTS: There were 22,372 visits to the PCC between July 9 and November 30, 2013, and the Screening Tool was initiated at 11,774 visits (52.6%). In October and November 2013, the Screening Tool was initiated at 4,809 visits; of these visits: 3,198 patients were eligible for test offer (66.5%); 3,173 eligible patients were offered a test (99.2%), and 1,608 patients (43.5%) who were offered a test did not opt-out. Of those patients who did not opt-out of HIV testing, 922 (57.3%) have had the test completed.

CONCLUSIONS: This analysis describes the implementation of a triage-staff initiated routine HIV screening program using laboratory-based HIV tests rather than rapid tests. Implementation of routine screening increased HIV testing by 200%: in the two months prior to initiation of the routine HIV screening program, 3.5% of patients received an HIV test (315 tests/9,000 visits) compared to 10.5% of patients in October and November 2013 (922 tests/8,771 visits). Approximately 60% of patients who accepted HIV screening in October and November 2013 have already completed the test and many patients will likely complete their test before their next visit. HIV test offer rates were consistent with previous outpatient HIV screening programs using rapid HIV tests and were significantly higher than the 0.4% to 20% offer rates reported in previous literature for provider-initiated screening. Although rapid HIV tests have been used in earlier studies because of their convenience, rapid tests require more up-front costs and staff training. These data indicate a benefit to coupling non-rapid HIV testing with other tests ordered in PCC's. Future studies should focus on identifying and addressing patient barriers to accepting routine HIV screening.

IMPLEMENTATION OF THE PATIENT CENTERED MEDICAL HOME (PCMH) IN THE VETERANS HEALTH ADMINISTRATION (VHA); ASSOCIATIONS WITH CLINICAL OUTCOMES, PATIENT SATISFACTION, PROVIDER BURNOUT AND UTILIZATION Karin M. Nelson¹; Christian Helfrich¹; Haili Sun¹; Paul Hebert¹; Chuan-Fen Liu¹; Emily D. Dolan¹; Leslie Taylor¹; Edwin Wong¹; Charles Maynard¹; Susan Hernandez¹; William J. Sanders¹; Idamay Curtis¹; Ian A. Randall¹; Gordon Scheetman³; Richard Stark³; Stephan D. Fihn^{2,1}. ¹VA Puget Sound Health Care System, Seattle, WA; ²Veterans Health Administration, Seattle, WA; ³Veterans Health Administration, Washington, DC. (*Tracking ID #1938591*)

BACKGROUND: In 2010, the Veterans Health Administration (VHA) began implementing the patient centered medical home (PCMH) at all clinical sites. The Patient-Aligned Care Team (PACT) initiative aims to improve experiences and health outcomes through team-based primary care, improved access and care management for over 5 million Veterans. To evaluate progress and outcomes throughout the system, we sought to create a measure of PCMH implementation and relate variation in implementation to key outcomes.

METHODS: We conducted an observational study using: (1) VHA clinical and administrative data for >5.6 million Veterans who received primary care at 913 VHA hospital- and community-based clinics; (2) 75,101 responses to a national patient survey that included the Consumer Assessment of Health Plans (CAHPS)-PCMH module and was administered to a weighted, random sample of Veterans who

received outpatient care from June–December 2012; and (3) 5,404 responses to a survey distributed to all VHA primary care providers and staff in June 2012. Composite scores were constructed for 8 core domains: access, continuity, care coordination, comprehensiveness, self-management support, patient-centered care and communication, shared decision-making and team-based care. Our main outcome measures were patient satisfaction (defined by a provider rating from 0 to 100), provider burnout (defined by the Maslach Burnout Inventory - MBI), utilization (hospitalization and emergency room use), and VHA clinical performance measures.

RESULTS: 53 items were included in the PACT Implementation Progress Index (Pi2). Among the 77 sites achieving the most effective implementation (i.e., Pi2 score in the top decile), measures of patient satisfaction, provider burnout, and hospitalization and emergency room utilization were all significantly more favorable than among 87 clinics with Pi2 scores in lowest decile. Patient satisfaction was meaningfully higher among sites that had effectively implemented PACT than those that had not (mean rating for satisfaction with provider 9.33 vs. 7.53, $p<0.001$). A similarly favorable pattern was observed for provider burnout measured by the MBI emotional exhaustion subscale (2.29 vs. 2.80 respectively, $p<0.05$). Emergency department encounters were significantly lower at sites with more rather than less effective implementation (188 encounters/1000 patients vs. 246, respectively, $p<0.001$). Among sites with Pi2 scores in the highest decile, there was an estimated average reduction of 13.4 % from baseline in admissions for ACSCs per 1,000 patients under age 65 attributable to PACT compared with a 3.0 % decrease among sites with less effective implementation of PACT. Twenty-three of 50 clinical performance measures were significantly associated with Pi2 scores, of which 21 were more favorable at sites with Pi2 scores in the top decile. Overall, 43 of the 50 measures were higher at sites with the highest Pi2 scores ($p<0.0001$), including foot exams and A1c <9 % among patients with diabetes (90.0 vs. 85.6 % and 84.0 vs. 81.8 %, respectively), blood pressure <140/90 mmHg among hypertensive patients (82.0 vs. 78.0 %), influenza immunization (68.5 vs. 64.2 %), cervical cancer screening (92.8 vs. 86.7 %) and offering medications for tobacco cessation (96.2 vs. 93.4 %).

CONCLUSIONS: The Pi2 was highly associated with important outcomes for both patients and providers and will be used to track PACT implementation within VHA.

IMPROVING ANTIBIOTIC PRESCRIBING FOR ACUTE RESPIRATORY INFECTIONS USING BEHAVIORAL ECONOMIC PRINCIPLES: A CLUSTER RANDOMIZED TRIAL Jeffrey A. Linder^{1,2}; Daniella Meeker³; Mark W. Friedberg^{2,3}; Stephen D. Persell¹; Craig R. Fox⁵; Noah J. Goldstein⁵; Alan F. Rothfeld^{6,7}; Joel Hay⁷; Jason N. Doctor⁷. ¹Brigham and Women's Hospital, Boston, MA; ²Harvard Medical School, Boston, MA; ³RAND, Santa Monica, CA; ⁴Northwestern University Medical School, Chicago, IL; ⁵University of California, Los Angeles, Los Angeles, CA; ⁶COPE Health Solutions, Los Angeles, CA; ⁷University of Southern California, Los Angeles, CA. (*Tracking ID #1939232*)

BACKGROUND: Acute respiratory infections (ARIs) are the most common reason for inappropriate antibiotic use. Inappropriate antibiotic prescribing for nonbacterial infections increases the costs of care, the prevalence of antibiotic-resistant bacteria, and adverse drug events. Standard approaches to behavior change have had limited success in reducing inappropriate antibiotic prescribing. Interventions that apply behavioral economic and social psychology principles may be more effective. In a large, multisite randomized trial, we evaluated the effectiveness of behavioral economic interventions to reduce inappropriate antibiotic prescribing for ARIs.

METHODS: We randomized 49 Boston and Los Angeles primary care practices in a $2 \times 2 \times 2$ factorial design and enrolled 342 clinicians to receive up to three interventions for 18 months: 1) Suggested Alternatives: Through computerized clinical decision support, clinicians attempting to prescribe antibiotics for ARIs received a list of non-antibiotic treatment choices prior to completing the antibiotic prescription; 2) Accountable Justifications: When attempting to prescribe antibiotics for ARIs, clinicians were prompted to record an explicit justification that appeared in the electronic health record as a separate "Antibiotic Justification Note"; and 3) Peer Comparison: Clinicians received periodic email feedback with their inappropriate antibiotic prescribing rate and were informed if they were a "Top Performer"—in the top 10%—or they were "Not a Top Performer." We used logistic regression to assess the primary outcome, antibiotic prescribing for non-antibiotic-appropriate ARIs (e.g., colds, acute bronchitis, and influenza), adjusted for clinician-level pre-intervention prescribing rates.

RESULTS: To date—the study is over 90 % complete, finishing in Spring 2014—there have been 26,783 ARI visits to the 342 participating providers. Patients had a mean age of 49.0 years old and were 33 % male. The antibiotic prescribing rates for non-antibiotic-appropriate diagnoses from the pre-intervention to the

intervention period were, respectively, 38.7 % and 29.6 % for control clinicians; 45.3 % and 36.0 % for suggested alternatives; 29.1 % and 17.7 % for accountable justifications; and 30.7 % and 19.8 % for peer comparison. Suggested alternatives were not associated with a significant decrease in the primary outcome (odds ratio [OR], 1.02; 95 % confidence interval [CI], 0.80 to 1.31). There was a significant decrease in antibiotic prescribing for non-antibiotic-appropriate ARIs for accountable justifications (OR, 0.66; 95 % CI, 0.56 to 0.79) and peer comparison (OR, 0.71; 95 % CI, 0.55 to 0.92). There were no significant interactions between suggested alternatives, accountable justifications, or peer comparison.

CONCLUSIONS: In this ongoing cluster randomized trial, accountable justifications and peer comparison were associated with decreased antibiotic prescribing for non-antibiotic-appropriate ARIs.

IMPROVING BLOOD PRESSURE MEASUREMENT AMONG CLINICAL STAFF Lauren Block^{1,2}; Romsai T. Boonyasai³; Sarah J. Flynn⁴; Caroline Lentz⁵; Tammie Hull³; Lisa A. Cooper³. ¹Hofstra North Shore-LIJ School of Medicine, New Hyde Park, NY; ²Bloomberg School of Public Health, Baltimore, MD; ³Johns Hopkins University School of Medicine, Baltimore, MD; ⁴University of Maryland School of Medicine, Baltimore, MD; ⁵Johns Hopkins Community Physicians, Baltimore, MD. (*Tracking ID #1936977*)

BACKGROUND: Blood pressure (BP) measurement in office settings is frequently performed incorrectly, with consequent over- and under-treatment of hypertension. Reasons for this problem include decay in knowledge and drift in skills related to correct technique. We designed a concise online training program in accurate blood pressure measurement for an interdisciplinary group of clinical staff. We sought to evaluate whether this training program improved knowledge and attitudes, as well as performance of recommended techniques among staff.

METHODS: This training program was designed to provide continuing education within a long-term multimodal hypertension quality improvement (QI) project focused on reducing disparities in BP control. As part of the QI project, all medical assistants (MAs), registered nurses (RNs), and licensed practical nurses (LPNs) at six ambulatory internal medicine practices were trained and certified as proficient in BP measurement techniques at the beginning of the intervention, 18–24 months earlier. The training program consisted of a 30-minute online didactic module designed to refresh knowledge of recommended techniques. Topics included the rationale behind BP measurement; importance of a rest period, patient positioning, and taking multiple measurements; key features of the automated device; troubleshooting device errors; and measuring BP in emergency settings and special populations. Participants completed a 20 question pre- and post-test of knowledge and attitudes immediately before and after watching the training video. Trained research assistants performed direct observation of BP measurement at each clinical site for 3 months prior to and subsequent to rollout of the training modules in order to assess use of recommended techniques. Differences in responses to pre- and post-module knowledge and attitudes questions as well as direct observation data were analyzed using chi-square tests and simple logistic regression analysis.

RESULTS: All 88 clinical staff invited to participate viewed the module and completed the pre- and post-test (response rate = 100 %). Most participants were female medical assistants; 68 % were in their current job at least 3 years. LPNs were more likely to answer questions correctly than MAs and RNs, as were those in their current job at least one year. Demographic factors including age, gender, and race/ethnicity were not associated with higher scores. Baseline knowledge was lowest at the site with the largest underserved patient population, but no differences were found between the 3 sites with predominantly underserved populations and the other 3 sites. The total number of questions answered correctly improved following module completion (79.9 % vs. 93.1 %, $p<0.01$) as did the average score per participant (80.4 % vs. 93.4 %, $p<0.01$). Knowledge scores improved significantly among staff from all job types. Greatest improvement was seen in questions pertaining to patient positioning, measuring BP in patients wearing long sleeves, handling device errors, measuring BP in obese patients, and selecting the appropriate cuff size. Attitudes towards correct BP measurement did not improve significantly. One hundred twenty two direct observations were completed prior to training (20 per site) and 88 subsequent to training (15 per site). Direct observation data revealed no improvement in positioning. Following training, staff at the three sites with underserved patient populations were less likely to support the arm (84 % vs. 67 %, $p=0.03$) and place the arm at heart level (96 % vs. 67 %, $p<0.01$). However, subsequent to training, participants at all sites were more likely to explain the protocol to patients (60 % vs. 80 %, $p<0.01$), offer a rest period prior to measurement (66 % vs. 85 %, $p<0.01$), and record the average of three measurements (63 % vs. 95 %, $p<0.01$).

CONCLUSIONS: We found baseline knowledge gaps in basic techniques in BP measurement among active clinical staff, revealing the need for ongoing training and assessment. Knowledge of correct BP measurement technique improved significantly following a brief online module. Direct observation data revealed improved adherence to multiple measurements but not to elements of patient positioning. Supervised clinical training may be more effective in changing attitudes and behaviors in accurate blood pressure measurement. Differential approaches may be needed based on characteristics of the clinical site and patient population served.

IMPROVING INTERNAL MEDICINE RESIDENT PREPAREDNESS TO DIAGNOSE AND TREAT SUBSTANCE USE DISORDERS; EVALUATING THE IMPACT OF AN ENHANCED ADDICTION CURRICULUM Sarah E. Wakeman¹; Genevieve Pham-Kanter²; Meridale Baggett¹; Eric Campbell^{1,3}. ¹Massachusetts General Hospital, Boston, MA; ²University of Colorado Anschutz Medical Campus, Denver, CO; ³Mongan Institute for Health Policy, Boston, MA. (*Tracking ID #1938278*)

BACKGROUND: Substance use disorders (SUD) are the number one public health problem facing America, accounting for more morbidity and mortality than any other preventable health condition and affecting 16 % of the population. Despite providing care for large numbers of patients with addiction, a majority of internal medicine residents feel unprepared to treat SUDs and rate the quality of SUD instruction during training as fair or poor.

METHODS: This prospective study evaluated the impact of an enhanced SUD curriculum at Massachusetts General Hospital on internal medicine residents' self-perceived preparedness to diagnose and treat SUDs, their ratings of the quality and quantity of SUD education, and their basic knowledge of SUDs. The intervention was a didactic curriculum designed by a collaborative group of internists and psychiatrists with addiction expertise, incorporated into the inpatient noon conference, resident report, and ambulatory lecture series over the course of one academic year. Core topics included the neurobiology of addiction; motivational interviewing; SUD screening and diagnosis; withdrawal management; pharmacotherapy for alcohol and opioid use disorders; opioid overdose prevention and management; physician addiction; care for the hospitalized patient with addiction; and exposure to patients in recovery.

RESULTS: Following the intervention, 86 % of residents reported feeling prepared to diagnose addiction and 58 % of residents reported feeling prepared to treat addiction as compared to 74 % and 37 % respectively in the baseline survey. Three quarters of residents rated the overall quality of instruction as good or excellent and 98 % of residents reported that formal residency curriculum had a positive impact on their self-perceived preparedness to provide care to addicted patients. However, 39 % of residents still reported feeling unprepared to treat addiction. Residents who reported receiving an adequate amount of SUD instruction were more likely to feel prepared to diagnose and treat addiction. Nearly one third of residents (31 %) still rated the overall amount of instruction in addictions as too little. Additionally, the majority of residents reported issues with insurance or cost of care (88 %) and access to addiction treatment (80 %) had a negative impact on their self-perceived preparedness to provide care for patients with SUDs. Nearly all residents (96 %) noted time constraints also negatively impacted preparedness. The intervention did not significantly improve residents' answers to knowledge questions.

CONCLUSIONS: An enhanced didactic SUD curriculum for internal medicine residents resulted in improved self-perceived preparedness to diagnose and treat SUDs and higher quality ratings for SUD instruction. However, there was no significant change in knowledge. Limited access to addiction treatment negatively impacts resident self-perceived preparedness which highlights the need for overall policy changes related to SUD treatment in addition to educational reform. Given the complexity of SUDs, a comprehensive training model beginning in medical school, incorporating clinical experiences, and comparable to other chronic disease curricula is needed to adequately impact knowledge and clinical care.

IMPROVING PATIENT SATISFACTION THROUGH PHYSICIAN EDUCATION, FEEDBACK, AND INCENTIVES Gaurav Banka¹; Sarah Edgington¹; Namgyal Kyulo²; Tony Padilla²; Virgie Mosley²; Nasim Afsharmanesh¹; Gregg Fonarow¹; Michael Ong¹. ¹UCLA, Los Angeles, CA; ²UCLA Health System, Los Angeles, CA. (*Tracking ID #1936407*)

BACKGROUND: Patient satisfaction has been associated with improved outcomes and become a part of reimbursement. Physician communication skills should be taught during residency and individualized feedback is an effective way to allow

physicians to track their progress over time and compared to their peers. We aimed to evaluate an intervention to improve patient satisfaction focused on resident physicians and included education, frequent patient feedback, and incentives. We hypothesized that this intervention program would significantly improve Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) scores.

METHODS: This was a non-randomized pre-post study that took place from 2011 to 2012 at a large tertiary academic medical center. The intervention group was composed of internal medicine (IM) resident physicians and their patients. The control group was the rest of the hospital and the rest of the nation participating in the HCAHPS survey. The intervention implemented in 2012 provided IM resident physicians with patient satisfaction education through a one-hour conference, weekly real-time feedback on individualized patient satisfaction scores, departmental recognition and nominal (\$20 value) prizes for outstanding scores, and a \$100 incentive program for residents with >90 % of their patients reporting effective communication. We measured the post-intervention change in patient satisfaction on physician-related and overall satisfaction questions on the HCAHPS survey. For our analysis, we focused on the results involving communication with doctors and overall recommendation of the hospital. Our analysis focused on the following specific questions: Would you recommend this hospital to your friends and family? During this hospital stay, how often did doctors: 1) treat you with courtesy and respect? 2) listen carefully to you? 3) explain things in a way you could understand? Responders that did not answer all of the above questions were excluded. We adjusted for perceived patient health, admission through ER, age, race, patient education level, ICU stay, length of stay, and gender with a difference-in-differences regression analysis.

RESULTS: Our sample included 957 IM patients and 2028 non-IM adult control patients from the first two quarters of 2011 and 2012. The percentage of patients that responded positively to all three physician-related HCAHPS questions increased by 8.3 % in the IM and 1.3 % in the control cohorts (absolute difference 7.0 %, $p=.04$). The percentage of patients that would definitely recommend this hospital to friends and family increased by 6.5 % in the IM and 1.4 % in the control cohorts (absolute difference 5.1 %, $p=.04$). The national average for the HCAHPS outcomes studied improved by no more than 2.5 %. There was no significant change between cohorts in the percentage of patients that responded positively (choosing "always") to each of the three individual physician-related HCAHPS questions after introduction of the \$100 financial incentive.

CONCLUSIONS: Our intervention was associated with improvement in patient satisfaction with physician-patient communication and overall recommendation of the hospital. The \$100 financial incentive that was implemented was not associated with further improvement in patient satisfaction. This intervention can serve as a model for academic hospitals to improve patient satisfaction and avoid revenue loss in the era of Hospital Value-Based Purchasing, and to train the next generation of physicians on providing patient-centered care.

INCIDENTAL FINDINGS ON PRE-VENTRICULAR ARRHYTHMIA ABLATION IMAGING. WAS FOLLOW UP RECOMMENDED? Chelsea K. Ngongang¹; David Spragg^{1,2}. ¹Johns Hopkins Bayview Medical Center, Baltimore, MD; ²Johns Hopkins Hospital, Baltimore, MD. (Tracking ID #1939549)

BACKGROUND: Pre procedural imaging with computed tomography angiography (CTA) and/or magnetic resonance imaging (MRI) for ventricular arrhythmia ablation is routine in some settings to see the anatomy of the heart and its vessels. With this imaging being done, there are risks of incidental findings and the need of further workup of those findings. Discharge summaries have an important role in the communication of a patient's "in hospital" course to transition smoothly to resuming primary care. This study looks at the rate of incidental imaging findings and how often physicians document in the discharge summaries these findings and the need for follow up on them with the patient's primary care doctor.

METHODS: This is a retrospective study of 106 patients who received ablation for ventricular tachycardia, ventricular fibrillation, or premature ventricular complexes. The patient's procedures were done at Johns Hopkins Hospital during the time period of 2008–2013. Seventy-five were male, average age 54 years old and 31 females, average age 48 years old. Patient's information were obtained from physician procedure logs and were researched on the electronic medical record by the patient's medical record number. Only imaging from a maximum of 2 days before the procedure were used to evaluate. All other imaging were not considered a part of pre-procedure time course. The imaging modalities reviewed were, computed tomography angiography (CTA) and magnetic resonance imaging (MRI) of the chest radiology reports for each patient.

RESULTS: There were 32 of the 106 patients that had incidental findings on imaging (30.1 %). There were 35 total radiographic findings in the 32 patients. These included pulmonary nodules (18), pericardial effusions (4), a hiatal hernia (1), breast calcifications (1), liver lesions (5), aortic aneurysms (2), an esophageal mass (1), lymphadenopathy (2), and rough endocardium (1). Interventions were done on 5 patients due to incidental radiographic findings including; cardiac catheterization (1), tissue biopsies (3), and a PET scan (1). Radiologist final reports recommended follow up imaging or evaluation for 26 of the 32 patients (81.2 %) with incidental findings. The discharging physician recommended follow up or mentioned the incidental finding in the discharge summaries for 7 of the 26 incidental finding patients with radiologist specific documentation for recommended follow up (26.9 %). All of the 5 patients who later underwent interventions due to their incidental findings on imaging had documentation in their discharge summary of the imaging and need for follow up.

CONCLUSIONS: This retrospective study shows that incidental findings are quite common in pre procedural imaging for patients undergoing ventricular arrhythmia ablation. These incidental findings often require follow up imaging and/or evaluation that that may lead to interventions being done. Unfortunately these incidental findings are less often mentioned in the discharge summaries the primary care doctor may receive after the procedure that describes the patient's hospital course. It is important for primary care doctors to be aware of pre procedure imaging and obtain the results, because necessary follow up is not always communicated in discharge information.

INCREASED ACCESS TO PROFESSIONAL INTERPRETERS IN THE HOSPITAL ENHANCES LIMITED ENGLISH PROFICIENCY PATIENTS' UNDERSTANDING OF PROCEDURAL AND SURGICAL CONSENT Leah S. Karliner; Crawford H. Michael; Steven Gregorich; Adrienne Green; Sunita Mutha; Anna M. Napoles; Eliseo J. Perez-Stable. UCSF, San Francisco, CA. (Tracking ID #1939646)

BACKGROUND: Limited English proficient (LEP) patients are at risk for poor communication leading to errors and adverse events. Professional interpreters improve communication, appropriate resource use and patient satisfaction. However, access to professional interpreters in the acute hospital is challenging due to the frequent and brief nature of many interactions, time pressures, the need for advance scheduling of in-person interpreters, and the around the clock nature of hospital care. We evaluated the impact of the bedside interpreter intervention-placement of a dual-handset telephone with 24-hour access to professional interpreters at the bedside of every patient-on LEP patients' understanding of procedural and surgical consent.

METHODS: In order to evaluate the impact of access to professional interpreters on communication sensitive outcomes, we recruited two cohorts of hospitalized Chinese and Spanish speaking LEP patients from the cardiovascular, orthopedic, and general surgical floors of an urban academic medical center: one cohort before (pre-group) and one cohort after (post-group) implementation of the bedside interpreter intervention. We interviewed patients in each cohort in-person during their hospitalization. If the patient did not pass a cognitive screener or felt too ill to participate, we recruited a family surrogate. Among those participants who reported that they were awaiting or had already had a major procedure (e.g. cardiac catheterization) or surgery (e.g. CABG), we compared the two cohorts according to participants' report of having signed a consent form, whether they had all of their questions answered, and how well they understood the reason and the risks of the procedure/surgery.

RESULTS: Among the 214 participants, two-thirds were Chinese and one-third Spanish speakers; 56 % were women, average age was 70 (range 45–95), 88 % reported speaking English 'not a at all' or 'not well' and the remainder reported speaking English 'well' but preferred Chinese or Spanish for their medical care; there were no demographic difference between pre- and post- intervention groups. The majority (57 %) of participants both pre- and post- intervention were recruited from the cardiovascular floor, 28 % from general surgery and 15 % from orthopedics. At the time of the interview a total of 152 (84 pre- and 68 post- intervention) participants were either awaiting a procedure/surgery or had already had one. Among those 152 participants, post-intervention participants were more likely than pre-intervention participants to remember signing a consent form (93 % vs. 82 %; $p=.06$). More participants in the post-intervention group reported that they had all of their questions answered about the procedure/surgery (99 % vs. 89 %; $p=.02$). Likewise, post-intervention participants reported significantly better understanding of the reason for and risks of the procedure/surgery (table).

CONCLUSIONS: Placing a dual-handset telephone with 24-hour interpreter access at every bedside is associated with better understanding of the reasons for and risks of

major procedures and surgeries for LEP patients. Implementation of systems changes such as the bedside interpreter intervention to improve communication with LEP

patients in the hospital may help to increase patient engagement in their own care, and avert errors and adverse events.

INDIVIDUALIZED RISK COMMUNICATION AND LAY OUTREACH FOR THE PRIMARY PREVENTION OF CARDIOVASCULAR DISEASE IN COMMUNITY HEALTH CENTERS: PRELIMINARY RESULTS OF A RANDOMIZED CONTROLLED TRIAL Shreya Shah; Tiffany Brown; Ji Young Lee; Muriel Jean-Jacques; Namratha R. Kandula; Stephen D. Persell. Northwestern University, Feinberg School of Medicine, Chicago, IL. (*Tracking ID #1937875*)

BACKGROUND: Statin use for primary prevention of cardiovascular disease (CVD) has been shown to reduce CVD and all-cause mortality, yet fewer than half of high-risk individuals are treated with statins. CVD is the largest contributor to disparities in premature death by race and socioeconomic status; yet, rates of statin use among certain racial/ethnic and socioeconomic groups remain suboptimal. Data within electronic health records (EHR) can be used to identify individuals with CVD risk that is sufficiently high to warrant statin therapy. Lay outreach and individualized risk education could lead at-risk patients to seek and obtain treatment. We conducted a randomized controlled trial (RCT) at federally qualified health centers (CHCs), with a high proportion of minority and lower-income patients, to determine if a population health management intervention, compared to usual care, resulted in higher rates of documented statin treatment discussions. We report interim primary outcome results.

METHODS: This RCT was conducted within three CHC networks in Illinois and Arizona. Patients were identified systematically using EHR queries. Patients (men ≥ 35 and women ≥ 45 years old) with 10-year risk for myocardial infarction or coronary death of at least 10 % or greater, based on the Framingham Risk Score (FRS), with a visit to CHC within the past year, and no currently prescribed statin medication or previously diagnosed CVD or diabetes were included. The intervention consisted of a mailed letter providing individualized cardiovascular risk scores for each patient and encouraging patients to schedule a visit to discuss CVD prevention. The letter was followed by telephone outreach by CHC non-clinician care managers. Eligible patients from three waves separated in time were randomly assigned to receive the intervention immediately, or after a 1-year delay. The primary outcome was statin or cholesterol treatment discussion with a doctor or other primary care clinician within 6 months. This outcome was measured by chart review (interobserver agreement, kappa = 0.77) and included a composite of: (a.) statin prescription, (b.) statin recommendation, (c.) patient refusal of statin, or (d.) documented discussion about cholesterol treatment with no clear statin recommendation. Reviewers were blind to the study group assignment. An intention-to-treat approach was used and statistical significance was determined using an unadjusted chi-square test.

RESULTS: Of the 662 patients included in the study, 478 (72.2 %) patients have completed the 6 month observation period and are included in the interim analysis (89.5 % male, mean age 60.6 ± 9.4 years, mean LDL 133.1 ± 25.0 mg/dL, mean FRS 15.3 ± 5.2). Two hundred forty-four were randomized to intervention and 234 to control. Intervention group patients were more likely to have a documented statin or cholesterol treatment discussion within 6 months (23.8 % vs. 10.3 %, OR 2.73, 95 % CI 1.63–4.57, $p < 0.001$). Among patients in the intervention arm that met criteria for the primary outcome: 6.1 % had a statin prescription, 0.8 % had a statin recommendation without a prescription, 2.9 % had a patient refusal of statin, and 13.9 % had a discussion about cholesterol treatment with no clear statin recommendation. There was a significant difference in discussions about cholesterol treatment with no clear statin recommendation (13.9 % vs. 6.0 %, OR 2.54, 95 % CI 1.33–4.88, $p = 0.004$), but no significant difference in the other 3 categories. Intervention group patients were more likely than controls to have a CHC office visit within 6 months (70.5 % vs. 52.6 %, OR 2.16, 95 % CI 1.48–3.14, $p < 0.001$).

CONCLUSIONS: An individualized risk communication and lay outreach intervention targeted towards CHC patients at moderate to high risk for CVD led to a

moderately large increase in statin or cholesterol treatment discussions between patients and their clinicians. Most discussions, however, did not result in the patient receiving a statin prescription. Possible explanations include: physician reluctance to prescribe, patient reluctance to take medication, or a greater emphasis by patients and providers placed on cholesterol levels rather than CVD risk levels. Patient interviews and longer-term follow up of prescribing and laboratory results will help elucidate these factors further.

INFORMAL CAREGIVERS' EXPERIENCES OF SUPPORTING VETERANS THROUGH ANTIVIRAL TREATMENT FOR HEPATITIS C Rendelle Bolton¹; Jeffrey Solomon¹; Jack Clark¹; Karen Steinhauser^{4,5}; Eric Dieperink²; Kelly McMaken³; Keith McInnes¹. ¹Edith Nourse Rogers Memorial Veterans Hospital, Bedford, MA; ²Minneapolis Veterans Health Care System, Minneapolis, MN; ³Minneapolis Veterans Health Care System, Minneapolis, MN; ⁴Durham VA Medical Center, Durham, NC; ⁵Duke University School of Medicine, Durham, NC. (*Tracking ID #1938568*)

BACKGROUND: Hepatitis C (HCV) is the most common blood-borne virus in the United States and disproportionately affects the Veteran population, with sequelae including chronic liver disease, cirrhosis, and hepatocellular cancer. Antiviral treatment for HCV is complex and imposes significant burdens for patients, including substantial emotional and physical side effects. Little is known about the role of informal caregivers during antiviral treatment or how treatment impacts the relationship in the veteran-caregiver dyad. This study characterizes informal caregivers' experiences of supporting veterans during treatment for HCV, with emphasis on caregiving activities, experienced burden, attributes of the veteran-caregiver relationship, and areas of need.

METHODS: Semi-structured interviews were conducted with 13 veteran-caregiver dyads from two VA hospitals. All veterans were undertaking antiviral treatment for HCV. Participants were queried about treatment experiences, caregiver roles, interactions with clinicians, and resources and needs related to treatment and caregiving. Interviews were audio recorded, transcribed verbatim, and uploaded into NVivo 10 software to organize coding and analysis. Adapting principles of grounded theory, a codebook was iteratively developed by an interdisciplinary team until saturation was reached. Transcripts were coded to consensus by two trained researchers who met weekly. Data from veteran-caregiver dyads were then systematically compared and thematic domains related to caregiving activities, the veteran-caregiver relationship, burden, and areas of need were identified.

RESULTS: SAMPLE: Approximately half of the veteran-caregiver dyads were marital or intimate partners; the remaining caregivers included friends, siblings, and adult children of the veterans. All patients were male, while most caregivers were female. (1) CAREGIVING ACTIVITIES: Caregivers provided instrumental support, including transportation and assistance with housework and shopping; emotional support through listening to veterans' difficulties and providing encouragement; and informational support by helping veterans recall and understand medical information given to them at appointments. (2) VETERAN-CAREGIVER RELATIONSHIP: Emotional interactions were complicated; while many dyads reported increased tension, some also experienced greater closeness and fulfillment within the relationship. Caregivers' support was appreciated, yet it could also threaten veterans' feelings of self-sufficiency and independence as they struggled with limitations secondary to side effects and their commitments to complete their course of treatment. (3) BURDEN: Caregivers experienced both emotional and logistical burdens. The primary source of burden was veterans' depression, irritability, and fatigue caused by antiviral therapy. Awareness of the stigma associated with HCV was also present, and several caregivers worried about the future should treatment fail. Among intimate couples, challenges to sexual intimacy secondary to veterans' fatigue and anemia were also present. Logistically, for some caregivers, employment limited their ability

to engage in caregiving activities. (4) NEEDS: Caregivers' needs encompassed both informational and emotional support. While some caregivers attended the veterans' medical appointments regularly, many only received second-hand information about HCV from veterans and wished they knew more so that they could better understand and support veterans. Finally, few had adequate sources of personal support and often felt alone through the treatment process, particularly if the veteran was an intimate partner.

CONCLUSIONS: Caregivers can play a vital role supporting veterans through antiviral treatment for HCV, yet many in this sample felt under-informed, unsupported, and burdened. Clinicians should consider engaging informal caregivers as partners in the treatment of HCV, and ensure that caregivers receive increased informational and emotional support so that they may in turn better support veterans. Continued systematic study of informal caregiver roles in HCV treatment is needed and directions for future research will be discussed.

INFORMATION AND COMMUNICATION MEDIA USE BY FEMALE RESIDENTS OF PUBLIC HOUSING Shivani M. Reddy^{1,2}; Lisa Quintiliani^{1,3}; Deborah J. Bowen³. ¹Boston University School of Medicine, Boston, MA; ²VA Boston Healthcare, Boston, MA; ³Boston University School of Public Health, Boston, MA. (*Tracking ID #1936988*)

BACKGROUND: Obesity is associated with many chronic diseases and disproportionately affects individuals of lower socioeconomic status (SES), particularly among women. Information and communication technologies (ICT) offer an opportunity to provide obesity-related interventions widely with cost-effectiveness. Evidence suggests that internet, mobile, or social media based-interventions may promote obesity-related behavior change. However, the uptake of ICT among low-SES individuals is unclear. In this study, we examine the frequency of ICT use among a subgroup of low-SES individuals, female public housing residents, and also examine if ICT use varies across demographic, health, or obesity-specific variables.

METHODS: We examined socio-demographic variables collected at the baseline assessment of a cluster randomized obesity intervention designed for mothers/caregivers and their daughters. ($n=211$) The majority were Hispanic or Latino (64 %), Spanish-speaking (64 %), non-United States born (66 %), and had a high school education or less (64 %). Nearly 50 % were obese, a third overweight, and over 80 % sedentary. Mean age was 38.1 (SD 7.6). A subset of 158 subjects were surveyed on email, internet, social media (SM), mobile, and health information seeking (HI) internet use. We adapted the Pew Research Center typology of ICT users, defining a "user" as daily use or use within the last day. Comparisons between users and non-users and among users were made with student t-tests, chi square tests, and fisher's exact tests.

RESULTS: The majority accessed the internet in the past year (84 %), 75 % in the last day; accessed a SM site (85 %), 70 % in the last day; made one daily cell phone call (97 %); and sent at least one daily text message (84 %). ICT users were younger, more educated, US-born, and primary English speakers. For example, email users (vs. non-users) were 37 years old (vs. 39), and 43 % were English speakers (vs. 17 %). Email, internet, or multiple media users were more often White or Black ($p=0.84$, $p=0.03$, $p=0.39$, respectively). However, SM users and HI internet users were more likely to be Spanish speakers (58 % vs. 50 % for both, $p=0.6$ and 0.1) and Hispanic ($p=0.84$, $p=0.21$ respectively). There were no significant differences in obesity, or physical activity.

CONCLUSIONS: ICT use is common among low-SES female public housing residents, with mobile use for calls and texts most prevalent. Our findings of differential socio-demographics among users vs. non-users and among users themselves suggests that future public health interventions should consider targeting messages according to the cultural background of the targeted audience.

INPATIENT HEALTHCARE UTILIZATION AMONG PATIENTS WHO REQUIRE INTERPRETER SERVICES Jane Njeru¹; Paul Takahashi¹; Jon Ebbert^{4,1}; Jennifer St. Sauver²; Debra Jacobson³; Chun Fan³; Mark L. Wieland¹. ¹Mayo Clinic, Rochester, MN; ²Mayo Clinic, Rochester, MN; ³Mayo Clinic, Rochester, MN; ⁴Mayo Clinic, Rochester, MN. (*Tracking ID #1928126*)

BACKGROUND: More than 9 % of the US population has limited English proficiency (LEP). LEP is associated with multiple health disparities and suboptimal health outcomes. While LEP is a barrier to effective healthcare, it has been associated with increased outpatient healthcare utilization. However, its association with inpatient healthcare utilization remains unclear. The objective of this study was to

determine the association between LEP and inpatient healthcare utilization among adult patients.

METHODS: Design: This was a retrospective cohort study comparing emergency department (ED) visits and hospitalizations between patients requiring interpreter services (IS) and a cohort of age-matched English-proficient patients (non-IS patients). Setting and Participants: The study was set in a large multisite primary healthcare network in a medium-sized US city. The participants were adult patients who were actively empanelled to physicians in this practice for primary care. Measures and analytic procedures: Emergency Department visits and hospitalizations in 2012 were obtained from billing records of the 3 inpatient facilities in the county. Chart reviews were performed for all the study participants with at least 1 hospitalization or ED visit to confirm the event and review the associated diagnoses. Demographic data were obtained from registration information, while medical complexity data (summarized using the Charlson comorbidity index) was obtained from billing records. The total number of ED visits and hospitalizations during the 12-month period was compared by IS status, using a χ^2 test. Proportional hazard regression was used to assess the association between IS status and first ED visit or hospitalization, and results were presented as hazard ratios (HRs) with 95 % CIs. Multivariable models were used to adjust for the effect of age, sex, Charlson comorbidity index, and number of outpatient visits.

RESULTS: The cohort included 3,784 patients (1,892 per group). Patients who required interpreter services had significantly more total ED visits (841 vs 620; $P <.001$) and hospitalizations (408 vs 343; $P <.001$) than the non-IS patients. Regression analysis showed that the risk of a first ED visit were 60 % higher for IS patients than non-IS patients (unadjusted hazard ratio [HR], 1.6; 95 % CI, 1.4–1.9; $P <.05$), and risk of a first hospitalization were 50 % higher (unadjusted HR, 1.5; 95 % CI, 1.2–1.8; $P <.05$). These findings remained significant after adjusting for age, sex, medical complexity, and outpatient healthcare utilization. The reasons for the first ED visit and hospitalization differed between IS patients and non-IS patients; hospitalizations due to infectious, gastrointestinal, mental health, and genitourinary diagnoses were more common among IS patients than non-IS patients. Similarly, for ED visits, these same categories were also more common among IS patients, along with ear-nose-throat (ENT), ophthalmologic, dermatologic, dental, and trauma or assault diagnoses. Conversely, hospitalizations for musculoskeletal diagnoses were higher among non-IS patients, but this difference was explained almost entirely by elective joint arthroplasties.

CONCLUSIONS: Patients who required IS had higher rates of inpatient healthcare utilization compared with non-IS patients. Further research is required to understand factors associated with increased use of the ED and to develop sociolinguistically tailored interventions to facilitate appropriate healthcare in this population.

INSTITUTIONAL PREDICTORS OF MEDICAL STUDENTS' INTERACTIONS WITH THE PHARMACEUTICAL AND MEDICAL DEVICE INDUSTRIES James Yeh¹; Kirsten Austad¹; Jessica Franklin¹; Susan Chimonas²; Eric Campbell³; Jerry Avorn¹; Aaron Kesselheim¹. ¹Brigham and Women's Hospital and Harvard Medical School, Boston, MA; ²Columbia University College of Physicians and Surgeons, New York, NY; ³Massachusetts General Hospital and Harvard Medical School, Boston, MA. (*Tracking ID #1921316*)

BACKGROUND: Medical students frequently interact with pharmaceutical and medical device industries. Students receive biased information from these interactions, which may lead to non-evidence-based prescribing. Thus, medical schools have designed industry interaction policies regulating students' contacts with the industry. Professional societies have developed metrics to evaluate the strength of these policies. We compared metrics from two prominent professional societies and investigated which aspects of industry interaction policies were most closely associated with student outcomes. We also considered whether certain characteristics of medical schools were associated with their students' behavior and attitudes towards pharmaceutical marketing.

METHODS: A national sample of 1610 first- and fourth-year medical students answered survey questions on acceptance of gifts from the industry, interaction with sales representatives, and perceived adequacy of faculty and industry separation. We used hierarchical logistic regression models to determine the association between these reported outcomes with their schools' strength of industry interaction policies. The strength of the policies was measured using the American Medical Student Association (AMSA) PharmFree Scorecard and the Institute on Medicine as a Profession's (IMAP) Score. The model included adjustments for year in training, medical school size, and the level of National Institute of Health (NIH) funding received by the medical school. We also performed LASSO logistic regression

models to determine which policy domains were best associated with students' reported outcomes.

RESULTS: IMAP Score had a lower median value (1.75, interquartile range [IQR]:2–2.45) than the AMSA Score (2.18, IQR:1.5–2). The policy dimensions shared by AMSA and IMAP were not well-correlated (gift policies $r=0.28$, 95 % confidence interval [CI]:0.11–0.44); sales representative access policies $r=0.51$, 95 % CI:0.36–0.63). Students from schools with the highest-ranked industry interaction policies were less likely to accept gifts (AMSA Score odds ratio [OR]:2.65, 95 % CI:1.38–5.07; IMAP Score OR:2.19, 95 % CI:0.96–5.03) and less likely to interact with sales representatives (AMSA Score OR:2.99, 95 % CI:1.43–6.27; IMAP Score OR:2.71, 95 % CI:1.05–6.97) than students from schools with lowest-ranked policy scores. The association became non-significant when fully adjusted for NIH funding. Policies governing receipt of gifts (OR:1.01–1.30), meals (OR:1.13), and speaking bureaus (OR:1.02–1.13) were best associated with students' reported behavior of gifts receipt and sales representatives interaction. By contrast, policies regulating industry's role in educational activities (e.g., CME, travel compensation, and scholarship) were best associated with outcome of perceived adequate separation between faculty and industry (OR:1.01–1.32).

CONCLUSIONS: Policies restricting gifts had significant impact on students' behavior in reducing the receipt of industry gifts, sales representative interactions, and increased perception of adequate separation among the faculty and industry. Medical schools' strength of industry interaction policy, as determined by AMSA or IMAP scores, was associated with student reported behavior. However, this relationship was confounded by the level of NIH funding. As medical schools revise their industry interactions policies, limitation on the receipt of gifts should be emphasized and greater attention paid to less research-intensive schools.

INTENTIONAL AND INCIDENTAL SCREENING FOR ABDOMINAL AORTIC ANEURISMS IN OUTPATIENT PRIMARY CARE CLINICS Allison L. Ruff¹; Bo Hu²; Kathryn Teng¹; Michael B. Rothberg¹. ¹Cleveland Clinic Foundation, Cleveland, OH; ²Cleveland Clinic Foundation, Cleveland, OH. (Tracking ID #1933802)

BACKGROUND: In 2005, The U.S. Preventive Services Task Force (USPSTF) recommended one-time abdominal aortic aneurysm (AAA) ultrasound screening for men aged 65 to 75 who ever smoked. Reported screening rates have been 12.9 % to 26 %. CT, MRI, and non-aortic abdominal ultrasound all provide adequate visualization of the aorta, but may not be considered AAA screening by providers; therefore, screening rates may be higher than previously reported. The objective of our study was to evaluate rates of screening performed intentionally and incidentally (with other abdominal imaging), rates of redundant screening, and patient and physician characteristics associated with screening.

METHODS: Cross sectional study of 2 years of patient encounters (2007 and 2012) to determine AAA screening trends at the Cleveland Clinic. Data were collected from the electronic health record. We included all patients who were eligible for screening according to the USPSTF guidelines and were seen in a primary care office in the calendar year. For each study year, we evaluated rates of screening by patient age, smoking status (current or former), family history, and completion of other routine screenings including lipid panel, pneumonia vaccination, and colonoscopy. Patients were considered to have been screened for AAA if they underwent a CT, MRI, or ultrasound that visualized the aorta. We examined the rates of screening for patients of 861 primary care physicians. For physicians with at least 20 eligible patients in our data set, we created a multivariate model to assess patient and physician characteristics associated with screening.

RESULTS: There were 15,122 patients eligible for screening in 2007 and 11,068 in 2012. Most screening was completed incidentally by imaging for other indications. When considering all imaging that included the aorta, screening rates were 31 % in 2007 to 45 % in 2012. Screening rates with designated ultrasounds were 2.5 % for 2007 and 7.2 % for 2012, lower than previously reported. Of 1176 screening ultrasounds, 549 (47 %) were performed on patients who had already been screened via another imaging modality. Of 861 physicians, 211 had at least 20 eligible patients in the data set. Rates of any AAA screening by individual physicians ranged from 9 % to 81 % (median=40.9 %, IQR=[33.3 %, 51.3 %]), and rates of ultrasound screening ranged from 0 to 65 % (median=10.5 %, IQR=2.8 %, 20.3 %). Physician characteristics positively associated with screened patients included female sex (OR=1.47 [1.11, 1.96], $p=0.01$), younger age (OR=1.10 [1.03, 1.18] per 5-years, $p=0.01$) and specialty (Internal Medicine vs. Family Medicine, OR=1.72 [1.30, 2.28], $p<0.001$). Patients that were up to date on other age-appropriate screening were more likely to have AAA screening performed. Former smokers were just as likely to have a screening performed as were current smokers (37 % vs. 38 %, $p=0.59$). Patients

with a positive family history of AAA were more likely to have a screening (55 % vs. 37 % $p=0.001$). Patients older than 70 were more likely than patients 65–69 to have a screening (42 % vs. 36 %, $p<.001$).

CONCLUSIONS: AAA screening rates remain below 50 %, but are improving over time. Screening rate by individual physicians vary 9-fold, indicating substantial opportunity for educational interventions. Most AAA screening is completed incidentally, and some patients later undergo unnecessary ultrasound screening. Before ordering screening, physicians and EMR-based reminder tools should ensure that the aorta has not been previously visualized.

INTER-HOSPITAL TRANSFER STUDY (IHTS): HOW AN UNSTRUCTURED PROCESS IMPACTS PATIENT OUTCOMES Michael G. Usher; Christine Fanning; Karen Balonze; Di Wu; Dana Herrigel; Amay Parikh. Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ. (Tracking ID #1939238)

BACKGROUND: Inter-hospital transfers are an important yet understudied area in transitions of care. Timing of transfer, incompatible information systems, geographical distance, and patient acuity combine to create considerable obstacles to safe and efficient patient care. There are few studies that show how the process of triage, information transfer, and patient hand-off when moving patients between facilities impact clinical outcomes; therefore no consensus to standardize the process of coordinating inter-facility transfers exists. This study aims to fill that gap.

METHODS: This retrospective observational study reviewed the medical records of patient transfers from outside hospitals to three ICUs (medical, surgical, and cardiac) during December 2011 to December 2012. We gathered data about each patient's transfer including time of initiation, acceptance, and arrival. We analyzed the information that came with these patients for completeness using a standardized scoring system with two independent reviewers. Outcomes focused on adverse events, including in-hospital mortality, central line placement, transfusion, intubation, vasopressor initiation, ICU readmission, initiation of renal replacement. We used multivariate logistic regression to identify predictors of high-risk inter-hospital transfers.

RESULTS: 328 patients were transferred from 37 outside hospitals between December 2011 and December 2012. On average, patients were admitted for 4.24 days prior to transfer, and took 9.6 h to be relocated to RWJ once initial call was placed to transfer center. Adverse events occurred in 42 % of patients within 24 h of arrival, with an overall mortality of 18 %. Important predictors of adverse events were critical labs on admission ($p<0.001$), MPM/ApacheII score ($p<0.0001$), MICU admission (vs SICU/CCU) ($p=0.002$). Surprisingly, there was no correlation in severity of illness and the duration it took to complete the patient transfer. Patient arrival followed a bimodal distribution with peak arrival times at 6:00 pm (within 1 hour of shift change) and at 2:00 am. When controlling for MPM and transfer score, arrival during the night shift (50 % of the transfer population) was associated with an increase in adverse events ($p=0.006$), and a non-significant trend toward increased mortality ($p=0.17$).

CONCLUSIONS: Patients are often transferred between facilities in unstable condition or at inopportune times, associated with an increase in adverse events. We initially hypothesized that higher acuity transfers would be transferred more quickly; however, this is not the case. This suggests the relocation of critically ill patients may often be driven by administrative bottlenecks such as bed availability, causing a large proportion of patients to arrive at night at an increased adverse event rate. Improving the transfer process, including triage of patients based on severity of illness and physician staffing patterns, may improve clinical outcomes.

INTER-HOSPITAL TRANSFER STUDY (IHTS): INFORMATION HAND-OFF AND CLINICAL OUTCOMES OF CRITICALLY ILL PATIENTS Michael G. Usher; Christine Fanning; Karen Balonze; Di Wu; Dana Herrigel; Amay Parikh. Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ. (Tracking ID #1936900)

BACKGROUND: Transitions of care, whether within or between institutions, are an important source of medical errors, inefficiency, and unnecessary cost. Multiple studies demonstrate that improving the information quality of patient hand-offs during care transitions is associated with more efficient, less costly care, improved outcomes, and improved patient satisfaction. However, transitions of care involving patients transferred between facilities remains understudied. Inter-hospital transfers face multiple unique challenges, including uncertainty of timing, differing information systems, and geographical distance, which is compounded by patient acuity and

complexity. This study is designed to investigate whether the quality of patient hand-off impacts outcomes for patients transferred between facilities.

METHODS: We conducted a retrospective observational study of consecutive patients transferred to the MICU, SICU, and CCU from December 2011 through December 2012. Patient records were scored for the presence and completeness of discharge summary, history and physical, progress notes, consultations, images, and medication reconciliation (0 points if absent, 1 point if incomplete, 2 points if complete). The final transfer score was a percentage of the total possible points following two independent reviews. The primary outcome was in-hospital mortality. Secondary endpoints were adverse outcomes and a measure of over-utilization (that included transfer to another service within 24 h and duplicated labor). Severity of illness was adjusted by MPM0-III, and statistical significance was inferred with $p < 0.05$ by multivariate logistic regression.

RESULTS: 328 patients were transferred to three ICUs from 37 facilities during the study period. Patients were transferred with documents containing an average of 66 pages and a median transfer score of 60 out of a possible 100. There was no correlation between the length of the transfer documents and the transfer score ($p = 0.57$). When controlling for severity of illness, patients transferred with higher transfer scores had significantly lower mortality ($p = 0.022$, 95% CI -2.73 to -0.21). Similarly, higher transfer scores were associated with decreased adverse events within 24 h ($p < 0.001$, 95% CI -3.60 to -1.41) and over-utilization ($p = 0.001$, 95% CI -3.18 to -0.80). These results remained significant for all three ICUs separately. Of the individual components of the transfer score, multivariate logistic regression showed that by itself, the transfer of images was an independent predictor of in-hospital mortality ($p = 0.017$).

CONCLUSIONS: We show patients are frequently transferred with incomplete information, which leads to higher mortality and increased resource utilization. This correlation was significant across a highly variable patient population admitted to three distinct ICUs, demonstrating how the lack of a standardized approach to patient hand-offs can worsen outcomes for high risk patients. Currently, there are no guidelines detailing how to coordinate information during inter-hospital transfers. Systematic improvement of the hand-off process in these cases has the potential to improve patient important outcomes and provide higher value care.

INTEREST IN SMOKING CESSATION AND PRIOR CESSATION ATTEMPTS AMONG PATIENTS RECEIVING OFFICE-BASED BUPRENORPHINE TREATMENT Pooja A. Shah¹; Shadi Nahvi^{2,3}; Mia Brisbane³; Oni J. Blackstock^{2,3}; Chinazo Cunningham^{2,3}. ¹UCSF, San Francisco, CA; ²Albert Einstein College of Medicine, Bronx, NY; ³Montefiore Medical Center, Bronx, NY. (Tracking ID #1940824)

BACKGROUND: Tobacco use and tobacco-related disease are more prevalent among opioid-dependent patients than the general population. Despite this high tobacco burden, smoking cessation treatment is limited among opioid-dependent individuals. Office-based buprenorphine maintenance treatment (BMT) provides an important opportunity to offer smoking cessation treatment to opioid-dependent patients in a primary care setting. To our knowledge, interest in cessation and prior cessation attempts have not been described among buprenorphine-treated patients. To improve smoking cessation among BMT patients, we must first understand patterns of smoking, interest in smoking cessation and prior cessation attempts. Therefore, we sought to describe prevalence of cigarette smoking and patterns of prior cessation attempts among patients receiving office-based BMT.

METHODS: We interviewed 68 patients receiving BMT at a primary care clinic in the Bronx, NY. Physicians referred patients who were currently receiving BMT to the study. Participants were administered a questionnaire using audio computer-assisted self-interview technology in English or Spanish. Questionnaire domains included: socio-demographic characteristics, substance use, buprenorphine maintenance treatment, nicotine dependency, history of smoking cessation attempts, and attitudes about cessation. We report simple frequencies to describe smoking and smoking cessation in this population.

RESULTS: Of 68 participants, the mean age was 47 years; 69.1% were male, 67.6% Hispanic and 55.9% had a high school diploma or equivalent. The participants' median duration of BMT was just over 3 years. Overall, 95.6% had ever smoked cigarettes, 87.7% reported currently smoking, and 83.1% of those who had ever smoked had tried to quit. Among current smokers, 43.9% had a Fagerstrom Test for Nicotine Dependence score greater than 6, which corresponds to high dependency. Participants rated quitting smoking as important and were confident in their ability to quit smoking (on a scale from 1 to 10, with 1 = least important/confident and 10 = most important/confident, median importance score = 9, IQR=7,10 and median confidence score = 6, IQR=4,8). Of those who had ever tried to quit smoking, 78.5%

reported a prior medication-assisted quit attempt; the most common medications used were nicotine patch (63.1%), nicotine gum (47.7%) and varenicline (29.2%). The most common non-pharmacologic methods of quit attempts were quitting cold turkey (40.0%) and gradually cutting down the number of cigarettes smoked (32.3%). In addition, 15.4% reported use of electronic cigarettes to quit smoking.

CONCLUSIONS: Among opioid-dependent patients receiving BMT in a primary care setting, cigarette smoking was highly prevalent and an overwhelming majority of smokers had tried to quit unsuccessfully. Despite high levels of prior quit attempts, use of pharmacotherapy for smoking cessation and importance ascribed to quitting, most remained actively smoking. These results illustrate the need to develop better strategies to facilitate smoking cessation among patients receiving office-based BMT, and can be used to guide cessation strategies.

INTERHOSPITAL TRANSFER STUDY (IHTS): UNINSURED PATIENTS AND THE POTENTIAL FOR A MEDICAL LIMBO Christine Fanning; Michael G. Usher; Di Wu; Karen Balonze; Dana Herrigel; Amay Parikh. Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ. (Tracking ID #1936827)

BACKGROUND: Insurance coverage is an important contributor to health disparities. Uninsured patients are less likely to be hospitalized, receive less intense care overall, and have increased mortality among the critically ill. This occurs despite EMTALA, which mandates patient stabilization and treatment regardless of insurance coverage, and is designed to prevent premature transfer between facilities for financial reasons. EMTALA is balanced by recent privatization of medical care, which may increase incentive to transfer patients without insurance to other facilities as early as possible. This study aims to determine whether insurance status impacts the inter-hospital transfer process and outcomes in the current healthcare climate.

METHODS: We conducted a retrospective study evaluating consecutive patient transfers from outside hospitals to three ICUs (medical, surgical, and cardiac) during December 2011 through 2012. We compared insurance status of patients admitted from outside hospitals against those transferred from the wards or ED. Outcomes included in-hospital mortality, adverse events, and a measure of over-utilization (that included patients being transferred to another service within 24 h and duplicated labor); severity of illness was adjusted using MPM0-III. Outcomes and insurance status were compared by two tailed ANOVA and Fisher's Exact test, with statistical significance inferred by $p < 0.05$.

RESULTS: 328 patients were admitted to three ICUs from 37 outside facilities versus 3706 patients transferred from the wards or ED between December 2011 and December 2012. Self-pay or charity care patients were underrepresented in the inter-hospital transfer group (8%) when compared with those transferred from the wards or ED (14%, $p = 0.005$). Patients with insurance were conversely over-represented in the cohort transferred from outside hospitals ($p = 0.06$). This was not explained by differences in patient demographics or regional variations in insurance rates. Of the cohort transferred from outside hospitals, uninsured patients had a reduced length of stay at the prior hospital ($P < 0.0001$, 95% CI -2.786 to -1.189) and had a reduced severity of illness ($p < 0.0001$) when compared against patients with insurance. Severity adjusted outcomes including in-hospital mortality, adverse events, and over-utilization were similar between groups.

CONCLUSIONS: These data illustrate the complex effect of insurance status on a patient's likelihood of being transferred between facilities. Uninsured patients are transferred earlier and are of lower acuity than their insured counterparts, reflecting a motivation to move patients who cannot pay to other hospitals. On the other hand, the under-representation of uninsured patients who are actually transferred reflects hospitals' lack of desire to accept the uninsured. This creates the potential for a medical "limbo," in which insurance status complicates disposition in patients requiring specialized care, potentially exacerbating health disparities in underserved populations.

INTERHOSPITAL TRANSFERS: PATIENT CHARACTERISTICS AND OUTCOMES Cecelia N. Theobald^{1,2}; Stephan Russ³; Jesse Ehrenfeld⁴; Sunil Kripalani².

¹VA Tennessee Valley Healthcare System, Nashville, TN; ²Vanderbilt University, Nashville, TN; ³Vanderbilt University, Nashville, TN; ⁴Vanderbilt University, Nashville, TN. (Tracking ID #1939070)

BACKGROUND: The transfer of inpatients between hospitals is often necessitated by differential expertise and capacity among facilities. At some institutions, interhospital transfers constitute nearly 20% of all inpatient admissions and there is concern they may experience poorer outcomes. Much of the literature to date has examined small subpopulations of interhospital transfers (such as ICU, trauma, and

burn patients) without evaluating the characteristics of transfer patients as a population. Our objective was to compare the arrival characteristics and outcomes of interhospital transfer patients with those of patients directly admitted to a large academic medical center.

METHODS: We conducted a retrospective cohort study of patients transferred into an academic medical center and compared these with patients directly admitted during an 18 month period. Patients were excluded if they were transferred into the Emergency Department, Labor and Delivery, or admitted to burn or trauma services. Admission characteristics studied included demographics, site of admission (ICU vs. non-ICU), severity of illness (measured using the modified Elixhauser comorbidity index, range of possible scores -14 to 60), admitting service, and time of arrival. Outcome measures included length of stay, ICU length of stay, in-hospital mortality, and timeliness of initial inpatient care. Transfer patients were compared with non-transfer patients using simple univariate analysis.

RESULTS: Transferred and non-transferred patients had similar rates of ICU admission (46.5 % vs. 47.4 %, $p=0.53$) but transferred patients had higher severity of illness (mean modified Elixhauser score 12.0 vs. 9.3, $p<0.001$). Nearly two thirds, or 65 % of interhospital transfers arrived during overnight hours (6 PM to 7 AM), vs. only 56.2 % of non-transferred patients ($p<0.001$). Transferred patients waited on average 18 min longer for admission orders ($p<0.001$) and 15 min longer for non-PRN medication orders ($p<0.001$). Furthermore, transferred patients experienced significantly longer length of stay (6.0 vs. 3.1 days, $p<0.001$) and ICU length of stay (4.4 days vs. 2.5 days, $p<0.001$). Finally, transferred patients had over twice the in-hospital mortality of non-transferred patients (10.9 % vs. 4.9 %, $p<0.001$).

CONCLUSIONS: Interhospital transfer patients as a population have an increased severity of illness and experience longer length of stay, delays in initial inpatient care, and higher in-hospital mortality when compared with non-transferred patients. Hospitals may want to focus specific resources on this unique high-risk population.

Characteristic	Transfers (n=1715)	Non-transfers (n=6176)	p value

INTERN REFLECTIONS ON TRANSITIONS OF CARE EDUCATIONAL EXPERIENCE: INSIGHTS GAINED FROM PARTICIPATION IN POST HOSPITAL DISCHARGE HOME VISIT AND SKILLED NURSING FACILITY VISIT Rachel K. Miller¹; Zachary Smith¹; Shimrit Kedem¹; Samuel P. Katz¹; Karen B. Hirschman². ¹University of Pennsylvania, Philadelphia, PA; ²School of Nursing- University of Pennsylvania, Philadelphia, PA. (Tracking ID #1939559)

BACKGROUND: Transitions of care, particularly for the elderly and medically complex patient, are a high risk period of time. Through enacted legislation and proposed insurance payment changes, care transitions are under increased

scrutiny. Given the importance of recognizing and improving the current care transition system and ACGME competencies and milestones focusing on transitional care, medicine residences are increasing formal education on this topic. Our goal was to provide interactive post-hospitalization transitions of care learning experiences for interns and to determine key intern perspectives and insights gained from the curriculum.

METHODS: The 2012–13 UPenn internal medicine intern class participated in both post-hospitalization home visits with a visiting nurse (HVs) and skilled nursing facility (SNF) transitions experience with geriatric faculty member. Interns were asked to write a reflection essay on each experience with the following questions: "How has this visit changed your perception of discharge?", How will this experience change the way you care for patients?, Did anything in particular surprise you on the visit? The responses were entered into NVivo 10 for analysis. We used a modified grounded theory approach to the analysis. Codes were generated by the team based on the research question and the content of the data. Coders applied these codes to each line of text. A subset of narratives were double-coded for inter-rater reliability. Coding discrepancies were resolved by consensus.

RESULTS: Of the 46 interns, 36 and 34 completed the reflection essays on their HV and SNF experiences, respectively. Two overarching themes arose: the need to create more comprehensive yet articulate discharge instructions and a better appreciation of the patient's post-hospital care personnel (namely nurses and pharmacists). Additional themes included awareness of need to improve the post-hospital medication reconciliation and importance of assessing a patient's living situation and social support system before discharge. Interestingly, very few residents placed blame on the patients for any perceived breakdowns in care; most identified barriers to care were a lack of social support, difficult living circumstances, or messy and inadequate discharge instructions including misperceptions or gaps surrounding follow-up care and medication management.

CONCLUSIONS: The intern transitions of care curriculum, out of the hospital, and into the homes and skilled nursing facilities of discharged patients, sought to teach key elements of safer discharge in an interactive format. The reflection essays revealed that the interns gained insights into the importance of effective communication (accurate and informative medication reconciliation, comprehensive discharge summaries/instructions), the roles of interprofessionals in facilitating safe discharges, and the need for in-hospital teams to elicit potential health care challenges. Future goals will be using these to inform and improve specific parts of the discharge process and to determine whether there is a long-term impact in intern actions in discharge planning and patient outcomes.

INTERNAL MEDICINE RESIDENTS' EXPERIENCE OF CONTINUITY IN OUTPATIENT CARE: A QUALITATIVE STUDY Elisabeth Ihler. Montefiore Medical Center, New York, NY. (Tracking ID #1937099)

BACKGROUND: Provider continuity in ambulatory care has been shown to improve patient outcomes. However, maintaining patient continuity in outpatient care is difficult for internal medicine residents who work primarily in the inpatient setting. The effect of this conflict on residents' experience is unknown.

METHODS: Residents in the categorical internal medicine program at Montefiore Medical Center participated in a series of one-hour focus groups led by the investigator during their monthlong ambulatory rotations. A semi-structured questionnaire was used to guide the conversation. A total of 30 residents participated in 6 focus groups between December 2012 and October 2013, representing all 3 postgraduate years. A qualitative coding scheme was developed from the results of pilot focus groups and was applied to the transcribed interviews using commercial coding software.

RESULTS: Four major thematic domains emerged from the interviews. Residents highly valued the continuity relationship, particularly for its educational benefit. However, they reported great difficulty maintaining continuity with patients, primarily due to conflicting demands on their time and competing educational priorities. They also noted downsides to the continuity experience, including difficulty gauging how much effort to put into non-continuity visits with patients. In addition, residents used a number of strategies to manage their workload and the competing demands on their time, including keeping personal lists of patients, phone/email, overbooking, and use of urgent care slots for routine care.

CONCLUSIONS: Residents have complex perceptions of their experience of continuity in the ambulatory clinic, which are sometimes in conflict. They see significant value in the continuity experience as a whole both for themselves and for patients, but frequently regard it as impinging on their other work. Residents were particularly divided in how to manage visits with patients for whom they were not the primary care physician. They have developed a number of strategies to manage their ambulatory experience, some of which may have negative effects on overall clinic function.

INTERPROFESSIONAL COLLABORATIVE CARE: FACTORS ASSOCIATED WITH BEDSIDE INTERPROFESSIONAL ROUNDS Jed Gonzalo; Daniel R. Wolpaw; Erik B. Lehman; Cynthia H. Chuang. Penn State College of Medicine, Hershey, PA. (*Tracking ID #1937760*)

BACKGROUND: Care delivery in hospital-based medicine units requires collaboration between nursing staff and physicians to optimize care delivery. Although bedside interprofessional rounds is one method to promote interprofessional collaboration between nurses and physicians, this activity has not been well studied. We examined the incidence of bedside interprofessional rounds on medicine teaching services in one academic institution. We hypothesized resident and attending physicians with more experience, smaller team census size, and weekdays would be associated with higher occurrence of bedside interprofessional rounds.

METHODS: From November 2012–June 2013, an observational descriptive study of internal medicine faculty serving as inpatient attending physicians with house staff was performed. Each attending physician ($n=3/day$) was sent a daily electronic survey following rounding sessions to assess characteristics of rounds. Bedside interprofessional rounds were defined as “Encounters including the team of providers—at least two physicians plus a nurse or other care provider—discussing the case at the bedside with the patient.” Primary outcomes were: (1) incidence of bedside interprofessional rounds, and, (2) factors associated with increased occurrence of bedside interprofessional rounds. Covariates included resident level-of-training, attending physician years’ of experience, census size, and call day. Descriptive, Kruskal-Wallis, and multivariable logistic regression statistics were used.

RESULTS: Of 549 rounding sessions, 412 surveys were collected (75 % response) from 25 attending physicians. Bedside interprofessional rounds occurred with 64 % of patients (median 8.0 min/encounter), differing by unit (intermediate care 81 %, medicine-specific general medicine 63 %, multispecialty 57 %, $p<0.001$). Factors independently associated with increased occurrence of bedside interprofessional rounds were PGY-3/PGY-4 resident (OR 2.67, CI 1.75–4.06, vs. PGY-2), weekdays (OR 1.74, CI 1.13–2.69), team census size ≤ 11 (OR 2.36, CI 1.37–4.06), and attending physicians with ≤ 4 years’ experience (OR 2.15, CI 1.31–3.55).

CONCLUSIONS: The occurrence of bedside interprofessional rounds exceeded 50 % for all patients, with significantly more in medicine-based nursing units. Published numbers in recent years suggest bedside rounds infrequently occur, with <25 % of encounters occurring at the bedside. Our increased frequencies likely reflect our hospital’s initiatives to promote bedside interprofessional rounds (e.g. rounding lights designating the start of rounds, email reminders, education, etc.). As hypothesized, smaller team census size, weekdays, and teams with more experienced residents were associated with higher occurrence of bedside interprofessional rounds. Surprisingly, teams with less experienced attending physicians were also more likely to perform bedside interprofessional rounds. Reasons for this finding merit further study, but may relate to attending physicians’ desire to validate house staff decisions or sensitivity to leadership-directed initiatives. Systematic changes to census size caps, resident scheduling, and attending physician education and staffing may be required to increase the occurrence of bedside interprofessional rounds.

INVESTIGATION OF FIRST YEAR MEDICAL STUDENTS’ CAREER PREFERENCES Kimberly Clinite¹; Stephanie Kazantsev¹; Shalini Reddy¹; Jennifer R. Kogan²; Steven Durning³; Kent DeZee³. ¹University of Chicago, Pritzker School of Medicine, Chicago, IL; ²Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; ³Uniformed Services University, Bethesda, MD. (*Tracking ID #1938518*)

BACKGROUND: The United States physician shortage has been widely publicized, with primary care (PC) accounting for nearly half of estimated shortages. The

shortage of PC physicians is further exacerbated by medical students increasingly choosing non-PC and controllable-lifestyle (CL) residencies and specialty fellowships. The process of specialty selection is complex and begins early in medical training. The purpose of this study is to describe the career considerations of 1st year medical students to better understand the initial phases of career selection and to identify demographic factors predictive of specialty interests.

METHODS: This is a cross-sectional survey of 1st year medical students from 11 allopathic medical schools during the first 4 months of the 2012–2013 academic year. Schools were geographically diverse and represented public and private schools with varied social mission rankings. Site coordinators at each institution invited all 1st year medical students to participate via e-mail in the survey by completing an on-line questionnaire. Two reminders were sent before closing the survey at 6 weeks. The 31-item questionnaire was developed after review of current literature and modified based on discussion with the target population, experts, and testing of items for clarity. Students were asked to indicate their most likely specialty choice if they “had to choose today.” If this specialty choice was family medicine, internal medicine (general), or pediatrics, the student was classified as PC. If the specialty choice was PC, general surgery, internal medicine (sub-specialty), medicine-pediatrics, neurosurgery, OB-GYN, orthopedics, or urology, the student was additionally classified as selecting a non-controllable lifestyle (non-CL) specialty. All remaining specialties were classified as CL. Further items asked about demographic factors and educational history. Comparisons were made with chi square.

RESULTS: Overall response rate for the questionnaire was 60 % (1020/1704). PC was the first choice for 24 % (242/1006) of students. Women were more likely to select PC than men (30 % vs. 17 %, $p<0.01$). CL specialties were the first choice for 31 % (311/1006) of students. More men than women selected a CL specialty (35 % vs. 27 %, $p=0.01$), as did never married versus married/currently engaged/domestic partner students (32 % vs. 23 %, $p=0.03$). Students with no anticipated medical school debt, as compared to students with any anticipated debt, were less likely to choose PC (17 % vs. 26 %, $p<0.01$) and more likely to select a CL specialty (37 % vs. 29 %, $p=0.04$). Age, time off between undergraduate education and medical school, having at least one physician parent, premedical debt, and scholarships were not associated with specialty choice.

CONCLUSIONS: Given the projected significant shortage of PC physicians, future studies should investigate reasons for the minority (24 %) of MS1 students expressing interest in PC specialties. Men and never married students were more likely than women and married/currently engaged/domestic partner students to select CL specialties. This may warrant further investigation into students’ considerations of lifestyle factors. Additionally, scholarships and smaller debt were not associated with selection of PC, suggesting that financial incentives during medical school may not be effective at increasing interest in PC as has recently been proposed in the literature.

IS A PHYSICIAN SCORECARD FOR DIABETES MANAGEMENT POSSIBLE? Ameena Madan Paramasivan; Eric Brown; Ari Robicsek; Liana K. Billings; Chad Konchak; Barry Barrios; Christopher Masi. NorthShore University HealthSystem, Evanston, IL. (*Tracking ID #1934156*)

BACKGROUND: Physicians play an important role in helping diabetics manage their disease. However, studies suggest that physician-level factors are associated with minimal variance in glycosylated hemoglobin (HbA1c). In contrast, patient-level factors, including age, race/ethnicity, duration of diabetes, number of comorbidities, and body mass index (BMI) appear to account for almost all of the variance in HbA1c. Although the extent of physician influence on glucose control is unclear, scorecards evaluating diabetes management are becoming increasingly popular. Not surprisingly, physicians want assurance that such tools include appropriate risk adjustment (i.e., sufficiently account for patient-level factors that affect glucose control). The goals of this study were to develop a physician scorecard for diabetes management and evaluate the ability of this scorecard to identify physicians who are performing better or worse than expected after accounting for relevant patient characteristics.

METHODS: Using electronic health record (EHR) data from a large, integrated health system, we developed three logistic regression models to assess physician-level effects on diabetes control, defined as HbA1c < 8 %. Model 1 predicts whether HbA1c is greater than or equal to 8 % and produces an area under the curve (AUC) based upon which physician a patient sees. In this unadjusted model, the intercept varies by physician and patient-level data are excluded. Model 2 predicts the same outcome and

produces an AUC based upon 40 relevant patient-level factors, including age, race/ethnicity, duration of diabetes, number and type of co-morbidities, insurance type, marital status, and BMI. Using hierarchical logistic regression, Model 3 predicts HbA1c by nesting patient-level data according to physician. Using the unadjusted Model 1, we initially ranked each physician according to the proportion of patients whose most recent HbA1c was greater than or equal to 8 % (i.e., the observed proportion of uncontrolled diabetics). We then used the adjusted Model 3 to re-rank each physician based upon the difference between observed and expected (computed from Model 2) proportions of patients with uncontrolled diabetes.

RESULTS: A query of our EHR indicated that 16,850 (9.3 %) of 181,805 primary care patients aged 18 to 75 years have either type 1 or type 2 diabetes. Of these, the most recent HbA1c was greater than or equal to 8.0 % among 3,089 (18.3 %). All diabetic patients are cared for by 203 primary care physicians (PCPs), yielding an average panel size of 77. The AUC for Model 1 was 0.63, suggesting that the likelihood of having an HbA1c greater than or equal to 8 % is significantly associated with the physician that each patient sees. The AUC for Model 2 is 0.71, indicating that the model which includes only patient-level data is better at predicting uncontrolled diabetes than the model which includes only physician data. Model 3 provides 95 % confidence intervals for each physician's deviation from expected performance. Using this model, we found that 18 of 203 (8.9 %) PCPs performed better than expected and 14 of 203 (6.9 %) performed worse than expected based upon his or her patients' risk profiles and after adjusting for patient characteristics. In addition, physician ranking from the adjusted model differed from the unadjusted model such that half of the physicians initially in the top 5 % for diabetes control dropped out after risk adjustment.

CONCLUSIONS: Our results indicate that differences exist among physicians in the proportion of patients who have uncontrolled diabetes. These differences persist after adjusting for multiple patient covariates. Physician performance in diabetes management can be ranked without considering patient-level covariates. However, adjusting for these characteristics using HLM produces a different ordering of physicians and permits identification of physicians who perform better or worse than expected. This approach is replicable across health systems and can serve as the foundation for quality improvement strategies which include identification of best practices, as well as education and up-training of underperforming physicians. We conclude that a physician scorecard for diabetes management is possible with appropriate risk adjustment.

IS EXERCISE USED AS MEDICINE? ASSOCIATION OF FUNCTIONAL LIMITATIONS WITH MEETING STRENGTH TRAINING GUIDELINES AMONG OLDER US ADULTS Christopher Sciamanna¹; Jennifer Kraschnewski¹; Joseph Ciccolo²; Liza S. Rovniak¹; Carolina Candotti¹; Noel Ballentine¹. ¹Penn State Hershey, Hershey, PA; ²Columbia University, New York, NY. (Tracking ID #1936308)

BACKGROUND: For many older adults, the loss of independence is considered a fate worse than death. Unfortunately, functional limitations increase predictably with age due to loss of muscle mass and strength. Many of these functional limitations, however, can be reversed or even prevented by strength training. As a result, the American Heart Association and American College of Sports Medicine guidelines recommend that all adults participate in strength training activities at least twice each week. Further, these organizations launched the "Exercise is Medicine" initiative, in which doctors are encouraged to recommend physical activity to their patients as they would recommend any other effective treatment or preventive service. It remains unknown whether older adults with functional limitations, those with the most to gain, are participating in strength training. The aim of this investigation is to understand the association between functional limitations and meeting strength training guidelines, to understand whether exercise is being used as a medicine.

METHODS: Data from the 2011 National Health Interview Survey were analyzed. Frequency of strength training was assessed using the following question: "How often do you do leisure-time physical activities specifically designed to strengthen your muscles, such as lifting weight or doing calisthenics?" Responses were categorized to signify whether the individual performed these activities at least twice each week,

consistent with guidelines. Functional limitations were assessed using 9 self-reported questions that asked whether the individual had difficulty performing a range of common activities (ex. walking a quarter of a mile, push or pull large objects). A composite variable was created by summing the number of functional limitations per individuals, with 0 reflecting no difficulty performing any activity and 9 reflecting difficulty performing all activities. The composite variable was then divided into tertiles. Covariates included demographics variables and past medical history, consistent with variables shown to be associated with strength training in other studies. Analysis was limited to adults of 65 years or older. Multivariate analysis was conducted using multiple logistic regression analysis, with the dependent variable being meeting or not meeting strength training guidelines.

RESULTS: Overall, 16.1 % of adults 65 and older reported doing strength training activities consistent with guidelines. After adjusting for demographic covariates, those without limitations and 1–4 limitations had 1.92 times (95 % CI; 1.51, 2.41) and 1.39 times (95 % CI; 1.08, 1.80) the odds of meeting strength training guidelines, respectively, compared to those reporting 5–9 limitations. This pattern remained when demographic and past medical history variables (i.e. hypertension) were added to the model.

CONCLUSIONS: Our results show a consistent and troubling pattern; those with functional limitations were less likely to meet strength training guidelines. This suggests there is great potential for using strength training to improve the public's health and alternative strategies are needed to engage older adults, particularly those with functional limitations. Without a change in approach, unfortunately, the profound beneficial effects of strength training will continue to be used least by those who need it most, threatening the best intentions of "Exercise is Medicine."

IS GREATER ACCULTURATION ASSOCIATED WITH AN INCREASED PREVALENCE OF CARDIOVASCULAR RISK FACTORS AMONG HISPANIC IMMIGRANTS IN SOUTH FLORIDA? Aileen Chang; Kumar Ilangovan; Hua Li; Olveen Carrasquillo. University of Miami, Miami, FL. (Tracking ID #1939054)

BACKGROUND: Acculturation is the process of adapting to a new culture. Among immigrants living in the United States, some studies suggest that increased acculturation is associated with a higher prevalence of cardiovascular risk factors (CVDRFs). We examine the association of acculturation with physiologic and behavioral CVDRFs in Hispanics having poorly controlled diabetes in Southern Florida.

METHODS: We performed a cross sectional analysis of baseline data collected as part of larger randomized clinical trial of 300 Latino patients with poorly controlled diabetes ($\text{HbA1c} \geq 8.0\%$) recruited from the primary care clinics of Miami-Dade county's public hospital. We grouped subjects into acculturation tertiles using the Marin Short Acculturation Scale. Correlations between acculturation and physiologic measures including hemoglobin A1C (A1C), low density lipoprotein (LDL), systolic blood pressure (SBP), and body mass index (BMI) we examined using ANOVA. Correlations with behavioral measures including smoking status, physical activity (IPAQ), fruit and vegetable intake (BRFSS), and alcohol abuse (AUDIT-C) were examined using Chi-square comparisons.

RESULTS: The mean age of our patients was 56 ± 7 years, 55 % were female, and Cubans made up 29 % of our sample with no other Hispanic ethnic subgroup representing over 15 % of the sample. Nearly all of the Latinos in the study (85 %) had been living in the US for over 10 years, yet 47 % had the lowest possible acculturation score. However, acculturation scores were positively correlated with length of time in the US ($p < .01$). Of the eight outcomes examined only smoking status was associated with increased acculturation; 12 % of Latinos in the two lowest acculturation groups were current smokers versus 25 % in the highest acculturation group ($p = 0.02$). In contrast to our original hypothesis, we observed a non-significant trend of increased acculturation being associated with increased physical activity, increased fruit and vegetable intake, and lower alcohol use. We found no association between acculturation and A1C, LDL, SBP, or BMI.

CONCLUSIONS: With the exception of smoking, our data do not support a link between increased acculturation and higher prevalence of CVDRFs. Although our

study sampled a diverse Latino population, our findings may not be generalizable to Latinos in other parts of the country, recently arrived immigrants or to those without diabetes. Studies examining factors leading to increased smoking among more acculturated Latino immigrants may help guide smoking cessation and prevention efforts in this population.

IS HEALTHCARE PROVIDERS' RESPECT FOR PATIENTS ASSOCIATED WITH COMMUNICATION BEHAVIORS IN CLINICAL ENCOUNTERS?

Tabor E. Flickinger¹; Somnath Saha^{2,3}; Debra L. Roter⁴; Philip T. Korthuis³; Victoria L. Sharp⁵; Jonathan A. Cohn⁶; Richard D. Moore⁴; Mary Catherine Beach⁴.

¹University of Virginia, Charlottesville, VA; ²Portland VA Medical Center, Portland, OR; ³Oregon Health and Science University, Portland, OR; ⁴Johns Hopkins University, Baltimore, MD; ⁵St. Luke's Roosevelt, New York, NY; ⁶Wayne State University, Detroit, MI. (*Tracking ID #1935661*)

BACKGROUND: Communication training of health professionals emphasizes the acquisition of skills, yet attitudes towards patients may influence how healthcare providers interact. We aimed to investigate whether provider-reported respect for patients was associated with communication behaviors during clinical encounters.

METHODS: We analyzed audio-recordings of routine follow-up visits between 413 adult HIV-infected patients and 45 primary providers in 4 sites across the United States. The primary independent variable was provider-reported respect for that particular patient assessed immediately following the encounter with the item, "Compared to other patients, I have a great deal of respect for this patient" (strongly agree - strongly disagree). Responses were dichotomized to compare those who strongly agreed/agreed (higher respect) with those who were neutral or disagreed (lower respect). The outcomes were provider and patient communication behaviors assessed by the Roter Interaction Analysis System (RIAS). Covariates included patient and provider demographics and length of relationship. To examine associations between provider respect and communication, we performed negative binomial regressions with generalized estimating equations to account for clustering of patients within providers and adjusted for practice site and patient/provider characteristics.

RESULTS: Patients were predominantly male (66 %) and African-American (57 %), while providers were predominantly female (58 %) and white (71 %). Providers strongly agreed that they had a great deal of respect for 155 (38 %) patients, agreed for 182 (44 %), neutral for 66 (16 %), disagreed for 8 (2 %), and strongly disagreed for 2 (1 %). Patients who were non-white, not actively using drugs, and who were known less than 5 years were more highly respected than others. Younger and non-white providers reported more respect for patients than other providers. Providers' respect for patients was not associated with provider gender, or with patient age or gender. In multivariable analysis, providers with higher respect had a more positive emotional tone [IRR 1.10 (1.06–1.14)], engaged in more social chit chat [IRR 1.78 (1.11–2.84)], and more positive talk [IRR 1.20 (1.04–1.39)]. Patients of providers with higher respect had more positive emotional tone [IRR 1.05 (1.03–1.07)], engaged in more social chit chat [IRR 2.03 (1.16–3.56)], more positive talk [IRR 1.22 (1.08–1.39)], and gave more psychosocial information to their providers [IRR 1.60 (1.26–2.04)]. Encounters between patients and providers with higher respect were characterized by less verbal dominance [IRR 0.87 (0.78–0.96)] and more patient-centeredness [IRR 1.38 (1.12–1.71)].

CONCLUSIONS: Respectfulness is associated with a host of positive and patient-centered communication behaviors during medical encounters that are voiced by both providers and patients. The study results underscore the highly reciprocal nature of communication and suggest that interventions that enhance provider attitudes of respect may help improve communication and care quality.

IS STRENGTH TRAINING ASSOCIATED WITH MORTALITY BENEFITS?

A 15 YEAR COHORT STUDY OF US OLDER ADULTS Christopher Sciamanna; Jennifer Kraschnewski; Liza S. Rovniak; Erik B. Lehman. Penn State Hershey, Hershey, PA. (*Tracking ID #1936358*)

BACKGROUND: Guideline-concordant aerobic activity has consistent and powerful relationships with future mortality. Specific recommendations regarding strength training have come only more recently; in 2007 the American Heart Association (AHA) and American College of Sports Medicine (ACSM) recommended all adults participate in such activities at least twice each week. Although several smaller clinical studies have observed that greater amounts of muscle strength are associated with lower risks of death, few have studied the relationship between strength training behavior and mortality in a large national sample over an extended time period. We undertook this investigation to understand the association between meeting strength training guidelines and future mortality.

METHODS: Data from the 1997–2001 National Health Interview Survey (NHIS), linked to death certificate data found in the National Death Index, were analyzed. The main independent variable, guideline-concordant strength training, was assessed using the following question: "How often do you do leisure-time physical activities specifically designed to strengthen your muscles, such as lifting weight or doing calisthenics?" Responses were categorized to signify whether the individual performed these activities at least twice each week, consistent with guidelines. Covariates included demographics variables, past medical history (i.e. diabetes, hypertension, coronary artery disease, and non-skin cancer), and other health behaviors (i.e. body mass index, physical activity, alcohol use and smoking status), consistent with variables shown to be associated with strength training in other studies. Analysis was limited to adults of 65 years or older. Multivariate analysis was conducted using multiple logistic regression analysis, with the dependent variable being all-cause mortality.

RESULTS: Overall, 9.6 % of NHIS adults age 65 and older ($N=30,162$) reported doing strength training consistent with guidelines and 31.6 % died during the follow-up period. After adjusting for demographic covariates, those who reported guideline-concordant strength training had 46 % lower odds of all-cause mortality than those who did not (adjusted odds ratio: 0.64; 95 % CI: 0.57, 0.70; $p<0.001$). This association remained when adjusting for past medical history and health behaviors.

CONCLUSIONS: Guideline-concordant strength training is significantly associated with decreased overall mortality in older US adults. Unfortunately, only a minority of adults currently meet recommendations of strength training at least twice each week. This suggests we are far from engaging patients in the "Exercise is Medicine" campaign launched by the AHA/ACSM, where doctors are encouraged to recommend physical activity to patients as they would any other effective treatment. Identifying interventions to successfully engage older adults in guideline-concordant strength training has the potential to significantly reduce all-cause mortality in this population.

IS THERE AN ASSOCIATION BETWEEN CONTINUITY OF CARE AND DIABETES QUALITY MEASURES IN AN URBAN INTERNAL MEDICINE RESIDENT CLINIC? Georgia Giebel; Yaakov Y. Liss; Lauren Peccoraro. Mount Sinai Medical Center, New York, NY. (*Tracking ID #1939209*)

BACKGROUND: Continuity of care (COC) between patients and trainee providers in academic primary care clinics can be challenging. With poor COC, adhering to the growing number of quality metrics seems daunting. A few recent studies demonstrate that better COC can reduce hospitalizations, reduce cost, and improve glycemic control in diabetic patients. However, few studies have investigated whether improvements in COC can also improve adherence to quality measures in Internal Medicine (IM) resident primary care clinics. We sought to evaluate the association between resident provider continuity and diabetes management and adherence to diabetes related quality measures in an urban IM resident clinic. Primary outcomes included glycemic, blood pressure, and cholesterol control, as well as indicated diabetic screening tests. Secondary outcomes included the association between demographics and continuity, as well as correlations between eye and foot exams in individual patients.

METHODS: This study was conducted at Mount Sinai's Internal Medicine Associates (IMA) clinic, an urban (New York City) academic IM resident primary care clinic. A retrospective chart review was performed by abstracting data from the electronic medical records (EMRs) of 104 patients. Subjects were randomly selected from a convenience sample of diabetic patients seen in the clinic in December 2013. Selection criteria included patients who: 1) were seen for ≥ 3 scheduled visits with IM residents between 1/1/2013 and 12/31/13, 2) had a diagnosis of type II diabetes mellitus for >1 year, and 3) had been followed at our resident clinic for >1 year. Data regarding age, gender, rate of eye and foot exams documented for 2013, most recent blood pressure, most recent A1c, most recent LDL, ACE/ARB and statin use, and diagnosis and management of proteinuria (whether microalbumin was measured in 2013, the microalbumin/creatinine value, and use of ACE/ARB therapy) were recorded. Continuity for patients was calculated using the modified, modified continuity index (MMCI), a validated measure of patient-physician continuity that is independent of the specific primary care doctor (index results range from 0 to 1, with 1 being perfect continuity). Statistical analysis assessed the correlation between the MMCI score and diabetes process outcomes and quality measures (using Chi-squared test for two categorical variables, Pearson's or Spearman's Correlations for two continuous variables).

RESULTS: The average MMCI for the selected patients was 0.51. There were no significant associations between continuity, as measured by the MMCI, with the rate of eye exams, foot exams, blood pressure control, diabetes control, LDL level, or evaluation and management of proteinuria for patients. Analysis demonstrated that patients who were up to date with ophthalmologic screening were significantly more likely to be up to date with foot exams than those without ophthalmologic screening (75 % vs. 52 %, $p=0.029$). There were no clinically important associations with age or gender and continuity.

CONCLUSIONS: Unlike previous reports, our study did not show a correlation between better continuity and improved diabetes outcomes or adherence to quality measures. It is possible that other changes in our clinic related to our patient-centered medical home (PCMH), such as care coordination and physician-directed best practice advisories, helped improve physician adherence to quality metrics, and may have negated any impact of continuity. The correlation between foot and eye exams may indicate that motivated patients are more likely to follow up with all types of referrals. Some limitations of our study are the small sample size and focus on only one institution, as well as the lack of comparison to patient outcomes prior to the implementation of the PCMH initiatives. Given our findings, it is important to continue to investigate the impact of continuity on other important metrics, such as patient and physician satisfaction. In addition, our results suggest that there may be other factors that can help improve the quality of care in an urban academic primary care setting.

IS THERE GLUTTONY IN THE TIME OF STATINS? DIFFERENT TIME TRENDS OF CALORIC AND FAT INTAKE BETWEEN STATIN-USERS AND NON-USERS AMONG US ADULTS Takehiro Sugiyama^{1,2}, Yusuke Tsugawa^{3,4}, Chi-Hong Tseng⁵; Yasuki Kobayashi¹; Martin F. Shapiro^{5,6}. ¹The University of Tokyo, Tokyo, Japan; ²National Center for Global Health and Medicine, Tokyo, Japan; ³Harvard Interfaculty Initiative in Health Policy, Cambridge, MA; ⁴St Luke, Tokyo, Japan; ⁵David Geffen School of Medicine at UCLA, Los Angeles, CA; ⁶UCLA Fielding School of Public Health, Los Angeles, CA. (Tracking ID #1932359)

BACKGROUND: Guidelines recommend both diet therapy and statin use as treatments of high blood cholesterol. As the statin use has become prevalent, however, diet among statin-users may have relaxed due to changing regarded importance of diet therapy among continuing statin-users and secular change in the characteristics of newly prescribed statin-users. No study has shown whether the time trend of dietary intake among statin-users is different from that among non-users,

although the increase in caloric intake among general population is reported to have plateaued in the last decade. We aimed to examine the difference in the time trends of caloric and fat intake between statin-users and non-users among US adults during the time while the statin use has widened quickly.

METHODS: We conducted a repeated cross-sectional study using a nationally representative US sample of the National Health and Nutrition Examination Survey from 1999 to 2010. Study populations were non-pregnant adults. Caloric and fat intake was measured through 24-hour dietary recall, while statin use was determined through in-person interview. Generalized linear models with interaction term between survey cycle and statin use were constructed to investigate the time trends of intake for statin-users and non-users after adjusted for possible confounders. We calculated model-adjusted caloric and fat intake using these models, and examined if the time trends differ by statin use. Body mass index was also modeled and estimated for each survey cycle and statin use adjusted for possible confounders.

RESULTS: The proportion of statin-users more than doubled from 7.5 to 16.5 % over the decade of observation. Main analyses comprised 27,886 participants. In 1999–2000, the caloric intake was less for statin-users compared with non-users (2,000 vs. 2,179 kcal/day, $p=.007$). The difference between the groups became smaller as time went by, and there was no statistical difference after 2005–2006. Among statin-users, caloric intake in 2009–2010 was 9.6 % higher (95 % confidence interval (CI): 1.8 to 18.1, $p=.02$) than that in 1999–2000. In contrast, no significant change was observed among statin non-users during the same period. Statin-users also consumed significantly less fat in 1999–2000 (71.7 vs. 81.2 g/day, $p=.003$). Fat intake increased 14.4 % in statin-users (95 % CI: 3.8 to 26.1, $p=.007$) while not changing in non-users. Body mass index also increased more in statin-users (1.3 kg/m²) than non-users (0.4 kg/m²) in the adjusted model ($p=.02$).

CONCLUSIONS: Our results indicate that statin-users no longer consume fewer calories and less fat than non-users. Efforts aimed at dietary control may be becoming less intensive among continuing statin-users. The characteristics of newly prescribed statin-users may also have changed; those who initiated statin use in later study periods may have consumed more calories and fat than those who started in earlier study periods. Although the repeated cross-sectional study design precluded us from disentangling the mechanisms, our results indicated that caloric and fat intake among statin-users in 2009–2010 was significantly greater than in 1999–2000. We may need to reemphasize the importance of dietary modification for statin-users. At the same time, the relative roles of diet and statins may need to be reevaluated based on additional evidence and further discussion from multiple perspectives including effectiveness, cost-effectiveness and ethics.

IS TRAINING IN A PRIMARY CARE INTERNAL MEDICINE RESIDENCY PROGRAM ASSOCIATED WITH A CAREER IN PRIMARY CARE MEDICINE? A CROSS SECTIONAL ANALYSIS OF A 10-YEAR COHORT Marion Stanley; Bridget O'Brien; Rebecca L. Shunk; Sharad Jain; Katherine Julian; Robert Baron; Jeff Kohlwes. University of California, San Francisco, San Francisco, CA. (Tracking ID #1941668)

BACKGROUND: Multiple professional and governmental organizations including the Health Resources and Services Administration (HRSA) and the Council on Graduate Medical Education (COGME) have long endorsed primary care residency programs in order to promote a workforce that would ideally be composed of at least 40 % primary care physicians. In internal medicine, where the vast majority of residency graduates select medical subspecialties, primary care programs are intended to increase the number of graduates selecting and maintaining primary care careers. There is a paucity of data, however, as to whether primary care residency programs are associated with careers in primary care. Our study examines whether enrollment in a primary care internal medicine residency is associated with a career in primary care.

METHODS: We performed a cross-sectional analysis of all internal medicine residency alumni from 2001 to 2010 at a single large academic center via a 27-

question survey. Residents at our institution during this period trained in either a traditional categorical internal medicine track, or one of two primary care internal medicine tracks. We used Chi-Square analysis to compare the career outcomes of primary care and categorical residents.

RESULTS: We were able to contact 481 reachable individuals out of a total of 511 living alumni, of which there were 322 respondents (67 % response rate) to the survey. We compared 106 responses from primary care residents to the 169 responses from categorical residents and excluded all self-identified current fellows as well as graduates from the basic science residency track. A significantly higher percentage of primary care residents agreed that the majority of their current work is in primary care medicine (54 %) as compared to categorical residents (20 %) ($p<0.001$). A significantly higher percentage of primary care residents also agreed that the majority of their current work is with underserved populations (54 %) as compared to categorical residents (27 %) ($p<0.001$). While 92.5 % of primary care residents agreed or strongly agreed that they were interested in a career in primary care medicine prior to starting residency, only 63 % agreed or strongly agreed that they were interested in a career in primary care after residency. Notably, 30 of the 34 residents (88 %) who lost interest in a primary care career during residency agreed or strongly agreed that their ambulatory experience during residency influenced their career choice.

CONCLUSIONS: More primary care internal medicine residents practice a primary care career and work with underserved populations than categorical internal medicine residents. This study demonstrates the effectiveness of primary care tracks in internal medicine programs in meeting national workforce goals. A number of primary care residents, however, lose interest in primary care during their residency training. Improving outpatient clinical experiences may be an important factor to further primary care residents' interest in primary care careers.

JAPANESE INTERNATIONAL MEDICAL GRADUATES: A QUALITATIVE STUDY OF THEIR MOTIVATIONS FOR AND REFLECTIONS ON U.S. TRAINING, AND RELATIONSHIP TO THE ADVANCEMENT OF JAPANESE MEDICAL EDUCATION Brian S. Heist¹; Haruka Torok². ¹University of Pittsburgh Medical Center, Pittsburgh, PA; ²Johns Hopkins University, Baltimore, MD. (Tracking ID #1930414)

BACKGROUND: Most IMGs have trained in English in their home country and are motivated to pursue U.S. clinical training, in part, by improved financial status and job opportunities. The influences of societal expectations and a culture of migration within the home country have also been described. Japanese physicians, by contrast, face a major language barrier, have low financial incentive and limited prospects of improved job opportunity after U.S. clinical training, and have a modest tradition of migration abroad. Japanese post-graduate medical education is in a state of flux, with fundamental teaching and standardization lacking compared to the United States, which may serve as motivation for foreign training. This study sought to explore Japanese IMGs' motivations for U.S. clinical training, their impressions of American versus Japanese post-graduate clinical training, and their relationship to the advancement of Japanese medical education.

METHODS: Using purposeful sampling of Japanese professional society memberships and interviewees' personal connections to identify participants with diverse career paths, two investigators conducted 23 semi-structured individual digitally recorded interviews of Japanese IMGs 1–15 years out from U.S. clinical training. Interviews were conducted in English. Through closed- and open-ended questions, we explored motivations to pursue U.S. training, impressions of American versus Japanese postgraduate clinical training, and endeavors subsequent to U.S. training including participants' relationships to the advancement of Japanese medical education. Interview transcripts were coded using an inductive thematic analysis to identify emerging themes that influenced subsequent interviews in an iterative fashion.

RESULTS: Of 12 participants working in Japan, there were 7 internists (4 subspecialists), 4 family physicians, and 1 pediatrician. Of 11 participants working in the U.S., there were 7 internists (5 subspecialists), and 1 physician each from family practice, transplant surgery, pediatrics, and pathology. Participants represented academic and non-academic settings. Post-graduate year upon starting U.S. training ranged from 1 to 13 years, with a median of 4 years. Duration since completing U.S. clinical training was 1–13 years with a median of 6 years. Emergent themes from the interviews included the following. (1) Motivations: A. Initial personal exposure to U.S. training methods. B. Scholarly pursuits to improve clinical skills, become better educators, or develop specific clinical expertise. C. No financial incentive; conversely there was financial sacrifice. (2) Impressions of U.S. versus Japanese post-graduate training: A. U.S. provides superior standardization, evaluations, feedback, mentoring, and teaching of clinical reasoning. B. More rigorous Japanese training schedule affords more continuity of care and deeper understanding of pathology. C. Japanese trainees and attending physicians seem more dedicated. (3) Relationship to advancement of Japanese medical education: A. Mentoring and teaching Japanese trainees or eager to do so. B. Publishing narratives of their U.S. training experiences. C. Confronting cultural and linguistic barriers to assimilation back into Japanese academia and implementation of Western educational methodologies within Japan. D. Building networks of marginalized Japanese IMGs and like-minded physicians to advance Japanese medical education.

CONCLUSIONS: Japanese IMGs commonly describe interest in U.S. clinical training originating in personal exposures to U.S. educational methods, with subsequent motivation to develop better clinical skills, become better educators, or develop specific clinical expertise. In reflecting on their U.S. clinical training, they admire the superior infrastructure, but perceive decreased dedication that appears related to duty hour limits not instituted in Japan. They demonstrate intense dedication to improving medical education in Japan, and through networks of Japanese IMGs and like-minded physicians, are surmounting cultural and linguistic barriers. This study deepens understanding of the relationship between Japanese and U.S. medical education, and the IMG landscape and, in turn, has implications for the advancement of medical education in Japan and elsewhere internationally.

KNOWING IS HALF THE BATTLE: HOSPITALIZED PATIENTS WITH ADVANCED CHRONIC KIDNEY DISEASE DO NOT CORRECTLY SELF-IDENTIFY Milda R. Saunders¹; Nisha N. Patel²; David Meltzer¹. ¹University of Chicago Medicine, Chicago, IL; ²University of Chicago Medicine, Chicago, IL. (Tracking ID #1939552)

BACKGROUND: Pre-renal replacement therapy (RRT) patient education leads improved clinical outcomes due in part to reduced central venous catheter use, increased uptake of peritoneal dialysis, and greater access to transplant for patients with end-stage renal disease (ESRD). Yet many patients with advanced chronic kidney disease (CKD) do not receive this important education due to lack of identification or understanding of their kidney disease. The hospital is an important, often overlooked, site for patient education and linkage to nephrology care for patients with advanced CKD. Many patients with advanced CKD are hospitalized in the 3 months prior to dialysis initiation, which represents an opportunity to identify existing CKD and to use a multidisciplinary approach to preventative care, patient education, patient-provider planning for future RRT needs. We sought to determine how often patients with ICD-9 coded CKD correctly identified themselves as having kidney disease.

METHODS: Using data from the University of Chicago Hospitalist Project, a large-scale study of inpatient physicians and patient outcomes, we examined data on 1,234 general medicine patients discharged between January 1, 2012 and March 31, 2012 with an ICD-9 code for chronic kidney disease, end-stage renal disease or transplant (585.0–585.9, 996.81) in their first 20 admission

diagnoses. We linked this data with Hospital Project patient surveys in which patients selected their chronic medical conditions from a list and were specifically asked if they had "kidney problems." Finally, we used logistic regression to determine what clinical and demographic characteristics are associated with patients with physician-identified CKD correctly self-identifying as having kidney disease.

RESULTS: In our sample of urban adult hospitalized general medicine patients, the mean age of 60.8 with 54 % females. Over 86 % of patients identified as African American and 4.2 % reported Hispanic ethnicity. Of the 125 patients with Stage 3 (moderate CKD, eGFR 30–59), only 25 % of patients reported having kidney problems. Of the 108 patients with advanced CKD, 60 % of patients with Stage 4 (eGFR 15–29) and 67 % of patients with Stage 5 (eGFR < 15) reported having kidney problems. The largest proportion of patients with CKD were coded as having CKD unspecified stage (535/1234). Of those, only 29 % reported having kidney problems. Factors significantly associated with the patients correctly self-identifying as having kidney problems include increasing CKD stage (OR 1.29, 95 % CI 1.17, 1.43), race other than African American (OR 1.38, 95 % CI 1.06, 1.80), all $p < 0.05$. Every 1 year increase in age was associated with an decreased likelihood of patients with CKD correctly self-identifying (OR 0.98, 95 % CI 0.98, 0.99). In multivariable analysis, CKD stage, non-African American race and younger age remained significantly associated with accurately reporting kidney problems, all $p < 0.05$.

CONCLUSIONS: In this urban, hospitalized sample, patient awareness of chronic kidney disease was low, even among patients with advanced chronic kidney disease (Stage 4 and 5). The hospital provides an important, underutilized opportunity to identify, educate and refer patients with advanced chronic kidney disease in order to increase their knowledge of their renal replacement options and, ultimately, to improve patient outcomes.

KNOWLEDGE, ATTITUDES, AND PRACTICES OF PHYSICIANS-IN-TRAINING RELATING TO COSTS OF CARE Celine Goetz¹; Kira L. Ryskina²; Tara F. Bishop^{3,4}. ¹New York-Presbyterian Hospital - Weill Cornell Medical Center, New York, NY; ²University of Pennsylvania, Philadelphia, PA; ³Weill Cornell Medical College, New York, NY; ⁴Weill Cornell Medical College, New York, NY. (Tracking ID #1935846)

BACKGROUND: Given the rising costs of health care, various medical societies have issued guidelines on cost-effective care. The concept of cost awareness has been incorporated into the System-Based Practice Core Competency for internal medicine residents. The purpose of this survey study was to investigate residents' perceptions about costs of care, as well as their knowledge and practice patterns as related to overuse guidelines.

METHODS: We conducted a survey of internal medicine residents in an urban academic medical center. The survey collected the following information: demographics, attitudes about overuse and cost-consciousness practice, knowledge of overuse guidelines, and self-reported frequency of use of services addressed in overuse guidelines. We pilot tested the survey with three out-going residents and revised it based on their feedback. Residents were asked to fill out the survey during a morning academic conference.

RESULTS: The response rate was 80 % (100/125). Among respondents, 24 % were PGY1, 36 % were PGY2, and 35 % were PGY3. The majority of residents (80 %) reported anticipating fellowship training in a specialty, rather than directly entering practice in primary care or hospital medicine (20 %). A large majority (94 %) of residents strongly agreed or somewhat agreed that "overuse is an important problem in medicine." Similarly, 87 % strongly agreed or somewhat agreed that "Doctors should know how much the tests and procedures s/he orders financially burden his/her patients", and 91 % strongly agreed or somewhat agreed that "Trying to contain the cost of medical care is the responsibility of every physician." In regards to overuse guidelines, 93 % reported no familiarity with the Good Stewardship Campaign, 78 % reported no familiarity with Choosing Wisely campaign, 60 % reported no familiarity with the American College of Physicians Back Pain Algorithm. However, 62 % of residents reported that they were "very familiar" with United States Preventative Services Task Force Guidelines. The majority of residents (62 %) disagreed or somewhat disagreed with the statement "I know how to find the costs of the tests and procedures I order" and 56 % of surveyed residents disagreed or somewhat disagreed with the statement "I know how much my patients have to pay out-of-pocket for medications I prescribe." Only a third of residents (31 %) agreed or somewhat agreed with the statement "During my residency training, I am receiving sufficient instruction on efficient use of health care resources." In

terms of self-reported practice, 81 % reported that they never or rarely ordered baseline EKGs on an asymptomatic, low-risk patients and 76 % never or rarely ordered DEXA screening for women under age 65 or men under age 70 without risk factors. For back pain, 76 % reported never or rarely imaging for low back pain within first 6 weeks of symptom onset. The most common reason for ordering this type of imaging was that the supervising attending physician requested it. Only 32 % reported never or rarely ordering a blood chemistry panel at a preventative visit of an asymptomatic patient. Almost a third of residents (27 %) reported ordering medical tests at least once in a month because of patient requests even though they did not feel it was indicated. Almost half (40 %) reported getting contacted at least once in a month by an insurance company questioning clinical necessity of a test ordered. The majority of residents (70 %) strongly agreed or somewhat agreed with statement "My patients think that the quality of their care is higher if I order more medical tests."

CONCLUSIONS: We found that internal medicine residents believe that overuse is a problem in medicine, but are largely unfamiliar with overuse guidelines and feel their training on this topic has been insufficient. Interestingly, self-reported practice patterns appear to be largely in-line with overuse guidelines but requests by supervising attending physicians seem to be a reason why residents order non-recommended tests. Future work should look at attitudes, knowledge, and practice of cost-conscious care in other training programs and in other specialties. Residency programs may need to educate residents and supervising attendings in order to encourage cost-conscious practice.

LAPSES IN MEDICAL PROFESSIONALISM: A LACK OF CONSENSUS ON APPROPRIATE SANCTIONS Bhavika Kaul¹; Cayla R. Teal²; Stephen B. Greenberg³. ¹Baylor College of Medicine, Houston, TX; ²Baylor College of Medicine, Houston, TX; ³Baylor College of Medicine, Houston, TX. (Tracking ID #1935269)

BACKGROUND: With recent literature increasingly citing strong associations between disciplinary actions taken against practicing physicians and prior unprofessional behavior observed in medical schools, the teaching of professionalism has received renewed attention. However, relatively little research has focused on methods for responding to professionalism lapses when identified. The goal of this study was to examine differences in perspective between medical students and faculty regarding appropriate consequences for lapses in medical professionalism - views we predicted would vary with level of training. We sought answers to three primary questions: was there consensus regarding sanction assignment within each cohort? How did views change with level of training? Were there scenarios that respondents felt were not remediable and thus meriting immediate expulsion?

METHODS: A cross-sectional sample of medical students (preclinical vs. clinical) and Internal Medicine faculty at Baylor College of Medicine were asked to assign sanctions (no sanction, verbal warning, written warning, probation, expulsion) to 25 scenarios involving first-time lapses in professionalism. For each scenario, respondents were asked to comment on reasons for sanctions assigned. A mixed methods (quantitative and qualitative) analysis of the data was conducted.

RESULTS: 513 medical students and 37 faculty members completed the survey. There was a lack of homogeneity in sanction assignment within cohorts. On average, there was a significant decrease ($p < 0.001$) in the severity of sanctions applied between preclinical and clinical years. The faculty were more like preclinical students in their pattern of sanction assignment. Clinical students were less likely to choose "expulsion" than their preclinical counterparts ($p < .001$); however, no group had >35 % of respondents selecting expulsion. Text responses suggested that preclinical students were more "policy-oriented," clinical students more "context-oriented" and faculty more "morality-oriented" in their justifications.

CONCLUSIONS: There were significant differences between preclinical and clinical students and between clinical students and faculty in the severity of sanctions applied but no significant differences between preclinical students and faculty on these measures. However, all cohorts favored sanctions with opportunity for remediation suggesting that, short of expulsion, there is a lack of consensus between students and faculty regarding appropriate consequences for lapses in medication professionalism. The hidden curriculum may play a significant role in sanction assignment and much of the variability seems to be guided by preservation of self. We must thus find ways to reconstruct the framework in which learners and faculty see themselves.

Percentage of Medical Students and Faculty Choosing "Long-Term" Sanctions for Each Dichotomized Item (Short Term vs. Long Term)*

LAY HEALTH LEADERS' EXPERIENCES LEADING A CHURCH-BASED DIABETES SELF-MANAGEMENT INTERVENTION FOR LATINOS Arshiya A. Baig³; Helio Zapata¹; Cara A. Locklin². ¹Pritzker School of Medicine, University of Chicago, Chicago, IL; ²University of Illinois, Chicago, IL; ³University of Chicago, Chicago, IL. (*Tracking ID #1934872*)

BACKGROUND: Lay health leaders have been effective in leading diabetes self-management interventions for Latinos. However, little is known regarding lay leaders' experiences leading these interventions, especially in the church setting. Our objective was to assess lay leaders' perceived challenges and satisfaction with leading a church-based diabetes self-management intervention in an urban Mexican American community.

METHODS: Our project was based in a low-income, Mexican American neighborhood of Chicago with high rates of diabetes morbidity and mortality. Lay health leaders were selected by the study's Community Advisory Board to undergo a 3-day training led by diabetes experts and community leaders. Lay leaders were trained to lead weekly 90-minute diabetes education classes at partnering churches as a part of a pilot study testing the impact of a church-based diabetes self-management intervention. We conducted qualitative semi-structured interviews with lay leaders after completion of the training and 1 year post training. We queried respondents regarding: 1) their motivations for joining the project; 2) strengths and weakness of the training they received; 3) perceived challenges and satisfaction with leading the classes; and 4) important characteristics of lay health leaders.

RESULTS: A research assistant interviewed lay leaders who completed training to lead the diabetes education classes as a part of a larger church-based self-management intervention. Interviews were conducted with three of four lay leaders at baseline and with two of three active leaders one-year post-training. All lay leaders were of Mexican descent, spoke English and Spanish, and were involved in their respective church communities. Reasons for wanting to be involved in the diabetes program included either knowing someone affected by diabetes or having diabetes themselves, wanting to learn more about the disease, and to give back to their community. Most participants had doubts about teaching the diabetes education classes due to the belief they had insufficient diabetes knowledge before the training. The training was well received and participants stated they gained a lot of knowledge about diabetes. However they wanted more hours of training and wanted a person with diabetes to share their experiences during the training. Reflecting on their year of teaching, class leaders were comfortable leading class sessions on their own and enjoyed teaching the lessons and interacting with the people in the classes. Lay leaders even noted healthy behavioral changes they made as a part of the class and the motivation they were able to give and receive from the participants. Lay leaders expressed comfort in discussing faith in class if participants mentioned it. They believed that future lay health leaders must be familiar with the Spanish language and the community that they are serving, be empathetic and open, and be very familiar with diabetes but not necessarily have diabetes themselves.

CONCLUSIONS: Lay leaders had many positive experiences teaching diabetes education classes, including learning more about diabetes, having an opportunity to give back to the community, supporting people with diabetes in managing their disease, and being motivated to make healthier lifestyle changes themselves. Future diabetes self-management interventions may consider measuring the impact of health interventions on lay leader health behaviors and impact of lay leader satisfaction on patient outcomes.

LAYERS OF DISADVANTAGE: SICKLE CELL DISEASE AND DISPARITIES IN THE QUALITY OF HEALTH CARE Mary Catherine Beach; Carlton Haywood; Sophie Lanzkron; Jennifer Haythornthwaite. Johns Hopkins University, Baltimore, MD. (*Tracking ID #1938901*)

BACKGROUND: Persons with sickle cell disease (SCD) are anecdotally known to experience deficiencies in the quality of the interpersonal care, but it is unclear how widespread these negative experiences are or whether these experiences are attributable to their predominantly African American race, to their health status, or to some other factors. Our objective was to assess potential disparities in the quality of healthcare provider communication experienced by African-Americans with and without sickle cell disease (SCD) in the United States.

METHODS: We assessed poor communication with healthcare providers using the Provider Communication subscale of the Consumer Assessment of Healthcare Providers and Systems survey, which asks respondents to assess the quality of their communication with providers over the previous 12-month period. Respondents are asked to indicate (never, sometimes, usually, or always) how often did doctors or other health providers listen carefully to you, explain things in a way you could

understand, show respect for what you had to say, and spend enough time with you? For analysis, the response options were dichotomized, with "never" or "sometimes" denoting poor provider communication. The SCD sample data was obtained from adult patients participating in a cohort study at academic medical centers in two cities. The national sample African-American data was obtained from published national estimates. Differences between the proportion of poor communication reported by SCD participants and the expected proportion from the corresponding national sample were compared using the binomial test. To assess the effects of poorer health, we also conducted stratified analyses by patient-reported health status.

RESULTS: Two-hundred sixty four African-American adults with SCD in total were included in this analysis. Slightly over half (54.2 %) were female, 75 % were between the ages of 18 and 44, and approximately 48 % perceived their health status as being poor or fair. The SCD sample was more likely than the national sample to report poor communication on each of 4 studied communication domains: Listening (22.3 % vs. 11.5 %, $p<0.0001$); Explaining (18.2 % vs. 11.6 %, $p<0.002$); Showing Respect (26.1 % vs. 9.5 %, $p<0.0001$); and Spending Enough Time (38.3 % vs. 16.2 %, $p<0.0001$). Poorer health status seemed to account for some of these differences: among those reporting the worst levels of perceived health ("poor" or "fair"), a greater proportion of SCD patients reported poor provider communication in 3 of the 4 domains, whereas among those with better perceived health, a greater proportion of the SCD sample reported poor provider communication in 2 of the 4 domains.

CONCLUSIONS: Persons with SCD in the U.S. are subject to disparities in the quality of the healthcare they receive that are not reducible to their predominantly African-American race or to their poorer health status generally. This patient population appears to be subject to other sources of disadvantage that negatively impacts the quality of the healthcare they receive.

LEARNING NEEDS OF VHA WOMEN'S HEALTH PROVIDERS Jessica Zuchowski¹; Alison B. Hamilton^{1,2}; Donna L. Washington^{1,3}; Kristina M. Cordasco^{1,3}. ¹US Dept of Veterans Affairs, North Hills, CA; ²David Geffen School of Medicine at UCLA, Los Angeles, CA; ³David Geffen School of Medicine at UCLA, Los Angeles, CA. (*Tracking ID #1936186*)

BACKGROUND: Although a growing number of women Veterans are using Veteran Health Administration (VHA) services for their health care, they are still a minority within the VHA patient populations. Many VHA providers have had historically small caseloads of women patients and therefore may need to supplement their current knowledge and skills in topics specific to caring for women Veterans. In primary care, new women patients are now preferably assigned to designated women's health primary care providers (PCPs) in an effort to concentrate female caseloads. Potential learning needs of these women's health PCPs have not been previously assessed. We explored the learning needs of VHA women's health PCPs.

METHODS: Using mixed methods, we conducted semi-structured telephone interviews with 10 VHA women's health PCPs in Southern California and Oklahoma. Interviewees were asked about their learning needs relevant to women's health. All interviews were audio recorded, professionally transcribed, and summarized. A summary template was used to capture key points within each domain of the interview guide. Summaries were analyzed for specific women's health topics that participants frequently identified as being of interest. We additionally administered 16 e-mail surveys to PCPs, 8 of whom were interviewees, and 8 have not yet been interviewed. Survey respondents were asked to rate their interest in getting additional education on a list of women's health topics using a four point Likert scale ("not at all interested," "mildly interested," "moderately interested," "very interested"). The topics are shown in the table. For each topic, we assessed the percentage of respondents that rated it as "very interested." Additional data collection is in progress.

RESULTS: Interviewees most frequently expressed interest in the topic of chronic pain management. Interviewees also frequently expressed interest in the following women's health topics: the impact of military service on women (e.g. military sexual trauma); abnormal uterine bleeding; medications during pregnancy and lactation. Other topics mentioned, but less frequently, included: dyspareunia; intimate partner violence; abnormal Papanicola smears; contraception; and caring for transgender patients. Interviewees also frequently mentioned a desire to receive updates on changing guidelines for best practice. Among survey respondents, topics with the highest percentage indicating that they are "very interested" were: management of abnormal Pap smear (67 %); contraception counseling (63 %); and evaluation of abnormal uterine bleeding (63 %).

Topics with the lowest percentage of respondents indicating they are “very interested” were: intimate partner violence screening (13 %); screening for military sexual trauma (13 %); and emergency contraception (19 %).

CONCLUSIONS: VHA women’s health PCPs express a wide range of learning needs. A fuller assessment of these learning needs, as well as the best ways in which PCPs’ learning needs can be met, is needed. VHA should work with medical education and women’s health experts, both within VHA and at affiliated universities, to continue assessing and addressing these learning needs so that VHA’s women’s health PCPs are equipped to provide optimal care to women Veterans. With the growing population of women Veterans, educational programs on the impact of military service on women will likely have relevance for PCPs both within and outside VHA.

Survey Topics

Contraception	Emergency contraception	Depression mgmt.
Infertility	Abnormal cervical path	Menopause mgmt.
Amenorrhea	Abnormal uterine bleeding	Abnormal mammogram
Uterine fibroids	Chronic pelvic pain	Breast mass
Preconception counseling	Initial tests in pregnancy	Fibromyalgia
	Pharmacology in preg/lact	Connective tissue disease
	Post-partum depression	Incontinence
		Interpersonal violence
		Military sexual trauma
		Osteoporosis diagnosis
		Osteoporosis mgmt.

LENGTH OF STAY AND IMPLEMENTATION OF GEOGRAPHIC STRUCTURED INTERDISCIPLINARY ROUNDING Madison Paddock; Alex Montero; Adam Wolk; Elizabeth Moroni; Amarin Sangkharat; Dara Ambrose; Michael Catalino; Alan Chung; Michael Adams. Medstar Georgetown University Hospital, Washington, DC. (*Tracking ID #1936784*)

BACKGROUND: Geographic localization consists of the co-localization of physician providers and their patients on the same inpatient units. Structured Interdisciplinary Rounding (SIDR) consists of daily, template-driven interdisciplinary rounding on patients among care providers. Both geographic localization and SIDR have been proposed as methods to optimize interdisciplinary communication and work efficiency. Among medicine inpatients, adoption of geographic localization of Hospitalist teams has been associated with increased provider productivity but a possible increase in length of stay (LOS). In a setting where geographic localization of medicine inpatients was already in place, adoption of SIDR had no impact on length of stay. The impact of concurrent implementation of geographic localization and SIDR on LOS has not been studied. In October 2012, the Department of Internal Medicine at MedStar Georgetown University Hospital (MGUH) concurrently implemented geographic localization and structured interdisciplinary rounding (GSIDR) on all teaching service patients. The purpose of this study is to assess the impact of implementation of GSIDR at MGUH on length of stay.

METHODS: A prospective cohort, pre/post intervention study design was employed. All patients admitted to the medicine teaching service 6 months prior to the implementation of GSIDR and up to 6 months after the implementation of GSIDR were eligible. The primary outcome was length of stay. The independent variable was GSIDR Status (before/after implementation of GSIDR). Covariates collected included demographics, case mix index, source of admission, and insurance payer status. LOS was log transformed to account for the non-normal distribution of LOS. Univariate analyses were carried out with student t-tests for categorical covariates and general linear models for continuous covariates. Multivariable analyses were carried out utilizing ANOVA. All analyses were carried out utilizing SAS.

RESULTS: 1470 patients were admitted to the teaching service in the 6 months prior to implementation of GSIDR. 2006 patients were admitted to the teaching service in the 6 months after implementation of GSIDR. In univariate analyses, implementation of GSIDR was associated with an increased LOS of 0.4 days ($p<0.001$). In multivariable analyses, there was no difference in LOS.

CONCLUSIONS: Concurrent implementation of geographic rounding and structured interdisciplinary rounding had a neutral impact on LOS. Surrogates of provider work efficiency did improve with an approximately 60 % drop in resident pages and 50 % decrease in daily resident provider miles walked documented in local, ancillary studies related to this GSIDR intervention. However, a significant rise in overall teaching service census (approximately 30 %) was noted in the GSIDR intervention period. A similar increase in census was noted in a prior study of the impact of geographic localization on LOS. Hence, it may be that improvement in work efficiency due to the implementation of GSIDR was attenuated by a concurrent rise in census.

GSIDR Baseline Characteristics: Hospital Medicine Discharges from GSIDR Floors Only

	Pre-GSIDR 4/1/12–10/ 1/12 (n=1470)	Post-GSIDR 10/2/12–4/ 1/13 (p=2006)	P value

LIFE CHAOS AND HIGH-RISK HEALTH BEHAVIORS IN ADOLESCENTS Avik Chatterjee¹; Matthew W. Gillman¹; Mitchell D. Wong². ¹Harvard Pilgrim Health Care Institute/Harvard Medical School, Boston, MA; ²UCLA, Los Angeles, CA. (*Tracking ID #1934803*)

BACKGROUND: Life chaos—physical and social disorder in one’s life—is associated with increased psychological distress in children. Life chaos may also be associated with undesirable health behaviors like smoking, drinking, drug use, and sexual activity in adolescents, but data are lacking.

METHODS: We analyzed cross-sectional data among 933 high-school students, aged 13–19 years, who in 2010–2011 took part in the Reducing Health Inequities through Social and Educational Change Study, of how school environments influence health behaviors among low-income, minority adolescents. The students completed a 90-minute interview assessing their demographics, substance use, sexual activity and other personal, familial, and psychosocial characteristics, including the 14 yes/no questions assessing Chaos, Hubbub and Order Scale (CHAOS). Possible score on CHAOS ranges from 0 to 14. In preliminary analysis we examined associations of CHAOS score in four groups (0, 1–2, 3–4, 5–14) with engaging in any of 4 risky health behaviors—any smoking, any drinking, or use of any illegal drugs in the previous 30 days, or having sexual intercourse in the previous 90 days. Because there was evidence of a threshold between 0 and the other 3 categories, we did all further analyses comparing 0 v. 1–14. We ran logistic regression analysis, adjusted for personal, psychosocial, and family-level variables that confounded the associations (changed estimates by >20 %). In an additional model, we added possible mediators to examine the extent of attenuation.

RESULTS: Mean (SD) age of the 933 students was 16.4 (1.3) years, 516 (55 %) were female, and 784 (84 %) were Latino. CHAOS score was 0 among 165 (18 %) students, 1–2 among 303 (32 %), 3–4 among 207 (22 %), and 5–14 among 258 (28 %). Prevalence of any risky behavior was 458 (49 %), including 87 (9.4 %) for smoking, 309 (34 %) for drinking, 206 (22 %) for drug use, and 247 (27 %) for having had sex. In unadjusted analysis, non-zero chaos score was associated with higher odds of participating in any risky health behavior (OR 1.9 [95 % CI 1.4, 2.8]) (Table). After adjustment for age, depression (Center for Epidemiologic Studies Depression Scale score >16), parenting style (neglectful, indulgent, authoritarian, authoritative, or average), family drug problems, family alcohol problems, and parent smoking, the OR was 1.5 (95 % CI 1.0–2.2). Including the possible mediators of cutting school, spending less time on homework, and choosing peers who engage in risky behaviors attenuated the adjusted OR to 1.3 (95 % CI 0.8–2.0). Examining each risk behavior separately, we found no independent association with having had sex (Table).

CONCLUSIONS: Non-zero CHAOS score among high school students was associated with higher odds of a composite outcome of smoking, drinking, use of any illegal drugs, or sexual activity. Cutting school, spending less time on homework, and choosing peers with poor health behaviors partially explained how life chaos

might result in increased participation in undesirable health behaviors. If these findings are replicated in prospective studies, school- or home-based interventions to decrease life chaos may reduce risky health behaviors in adolescents. These behaviors have significant effects on chronic adult diseases and life expectancy and it is important to understand modifiable factors that might deter initiation of these behaviors, which typically begin during adolescence.

Cross-Sectional Associations of the Presence of Life Chaos With 4 Risk Behaviors among 933 Adolescents age 13–19 years

	Unadjusted	Adjusted for Confounders ¹	Adjusted for Confounders and Possible Mediators ²
Odds ratio (95 % CI) for CHAOS score 1–14 v. 0			
Smoking in past 30 d	5.5 (2.1, 14.4)	2.4 (0.9, 6.2)	2.0 (0.7, 5.2)
Drinking in past 30 d	3.5 (2.2, 5.5)	1.9 (1.2, 2.9)	1.6 (1.0, 2.6)
Illegal drugs in past 30 d	2.0 (1.3, 3.3)	1.4 (0.8, 2.3)	1.2 (0.7, 2.1)
Sex in past 90 d	1.5 (1.0, 2.3)	0.9 (0.6, 1.4)	0.7 (0.5, 1.2)
Any of the 4 risk behaviors	2.6 (1.7, 3.9)	1.5 (1.0, 2.2)	1.3 (0.8, 2.0)

¹Age, depression, parenting style, family smoking (for smoking), family alcohol use (for alcohol), family drug problems (for drugs) ²Additionally adjusted for cutting school, time spent on homework, peer smoking (for smoking), peer alcohol use (for alcohol), peer drug use (for drugs), peer sexual activity (for sex)

LIMITED ASSOCIATION BETWEEN HOSPITAL FINANCIAL PERFORMANCE AND QUALITY OF CARE Oanh K. Nguyen; Anil N. Makam. University of Texas Southwestern Medical Center, Dallas, TX. (*Tracking ID #1938018*)

BACKGROUND: Increasing attention has been given to the role of hospital profits in contributing to the excessive cost of U.S. health care. However, little is known about the relationship between hospital financial performance and quality of care. We hypothesize that robust hospital financial performance is associated with higher quality of care, through ongoing investments in infrastructure, quality improvement and improved reputation through publicly reported quality measures.

METHODS: We merged data from the 2011 Hospital Annual Financial Data File from the Office of Statewide Health Planning and Development (OSHPD) in the State of California and the 2011 Hospital Compare web site. We included all general acute care hospitals for adults with both 1) comparable financial data and 2) data on 30-day risk-standardized mortality (RSMR) or readmission rates (RSRR) reported for at least one of the following: acute myocardial infarction (AMI), congestive heart failure (CHF) or pneumonia (PNA). We defined hospital financial performance as net revenue from operations (total operating revenue minus total operating expense). We performed a companion analysis using operating margin (net revenue from operations divided by total operating revenue) as an alternate measure of financial performance. Thirty-day RSMR and RSRR for AMI, CHF, and PNA were estimated from Medicare enrollment and claims data, risk-adjusted for age, sex, comorbid conditions, and indicators of patient frailty. We used linear regression to estimate the relationship between hospital financial performance and outcomes, adjusting for hospital characteristics and accounting for clustering of hospitals by owner. We performed a sensitivity analysis excluding 10 extreme outlier hospitals by financial performance (3 underperformers and 7 overperformers).

RESULTS: Of 280 hospitals, 23 (8 %) were teaching, 57 (20 %) were rural, 130 (46 %) were medium size (100–299 beds), 95 (34 %) were large size (\geq 300 beds), 147 (53) were associated with a hospital system, and 157 (56 %) were non-profit. Median net revenue from operations was \$3.8 million (IQR –1.7–17.6, range –185.3–227.2). After adjustment, we observed a weak trend towards decreased AMI mortality, PNA mortality and AMI readmission with increasing net revenue from operations (Table). However, after excluding 10 outliers, the observed decrease in AMI and PNA mortality rates were no longer statistically significant, but the relationship for AMI readmissions persisted. For each \$50 million increase in net revenue there was a 0.8 % decrease in the 30-day AMI readmission rate ($p=.001$). There was no relationship between operating margin and 30-day mortality or readmissions for AMI, CHF, and PNA.

CONCLUSIONS: There is a limited association between hospital financial performance and 30-day readmissions and mortality for AMI, CHF, and PNA. The improvement in mortality for AMI and PNA for hospitals with increasing net revenue from operations was largely driven by a small number of outlier hospitals, and was not associated with a hospital's operating margin. Outcomes for acute myocardial infarction may be more sensitive to financial performance due to increased availability of costly infrastructure (i.e., catheterization labs) among hospitals with more robust finances.

Table - Relationship Between Hospital Financial Performance and 30-Day Mortality and 30-Day Readmission Rates^a

	N	Median % (IQR)	Adjusted % change (95 % CI) per \$50 million increase in net revenue from clinical operations ^b	Outliers excluded ^c

<div align="left"><p style="padding-left : 10px">Readmission rate	270	18.2 (17.3–19.1)	–0.02 (–0.2 to 0.2)	0.2 (–0.2 to 0.6)

Abbreviations: IQR, interquartile range; CI, confidence interval

^a 30-day outcomes are risk-standardized for age, sex, comorbidity count, and indicators of patient frailty.

^b Adjusted for teaching status, metropolitan status (urban/rural), bed size, safety net hospital status, hospital ownership, and Medicare caseload, counting for clustering of hospitals by owner.

^c 10 hospitals were identified as outliers with respect to net revenue from operations (3 underperformers and 7 overperformers).

^d $p<.05$ for the Wald statistic.

^e Net revenue from clinical operations was modeled as a cubic spline function. The overall adjusted F-statistic was 5.6 ($p<.001$).

^f Net revenue from clinical operations was modeled as a cubic spline function. The overall adjusted F-statistic was 2.1 ($p=.08$).

^g Net revenue from clinical operations was modeled as a cubic spline function. The overall adjusted F-statistic was 2.4 ($p=.051$).

LOCAL PATIENTS, LOCAL STORIES: A LATINO CULTURAL COMPETENCY TRAINING PROGRAM FOR HEALTHCARE PROVIDERS Arshya A. Baig¹; Amanda Benitez¹; Anghela Z. Paredes²; Yue Gao¹; Lisa Monnot³; Kathy Brazda³; Michael T. Quinn¹. ¹University of Chicago, Chicago, IL; ²University of Illinois College of Medicine, Rockford, IL; ³Taller de Jose, Chicago, IL. (*Tracking ID #1934879*)

BACKGROUND: Although cultural competency training programs exist for healthcare personnel, these trainings may not focus on providers' local patient

populations, address the use of racial stereotypes, or provide information on local patient resources. Additionally, hearing stories of patients who are from the community may not only increase provider awareness of the challenges and successes of their Latino patients but may improve their effectiveness in managing their patients with diabetes.

METHODS: We designed a cultural competency training program for healthcare providers and staff that incorporated local patient stories, exercises on self-awareness of the use of stereotypes, skill building on patient-centered communication, and information on local patient resources. To tell the stories of local patients, we produced a video that included photographs taken by local patients with diabetes and their stories of challenges and successes in diabetes management. The hour-long training was led by a research team member. A community resource center presented information about local resources for diabetes patients. The trainings were conducted at community health centers with groups of providers and staff members in adult primary care, including physicians, residents, physician assistants, nurse practitioners, and registered nurses. We assessed the impact of the training on provider cultural sensitivity, self-awareness of stereotyping, awareness of Latino cultural and health beliefs, knowledge of the local community, awareness of local patient resources, and self-rated effectiveness in caring for Latino patients using a survey administered pre- and immediately post-training.

RESULTS: Trainings were conducted with four groups of providers and staff at two urban community health centers. Of the 37 providers and staff who participated in the trainings, six (16 %) were family medicine physicians, three (8 %) were internal medicine physicians, one (3 %) was an obstetrician/gynecologist, five (14 %) were family medicine residents, eight (22 %) were physician assistants, three (8 %) were advanced practice nurses, and 11(30 %) were registered nurses. The majority of participants were female (89 %), the average age of respondents was 37 ± 11 years, 39 % reported being of Hispanic ethnicity, and 11 % lived in the community. From pre-test to post-test, providers significantly increased their cultural sensitivity score from 33.6 ± 4.7 to 34.7 ± 5.0 ($p=0.03$). Provider awareness of their own stereotypes/biases concerning their patients increased from 3.7 ± 0.8 to 4.2 ± 0.7 ($p<0.001$). Awareness of Latino cultural and health beliefs increased from 14.4 ± 4.9 to 15.6 ± 4.8 ($p=0.04$). Knowledge of the local community increased from 1.3 ± 1.0 to 3.7 ± 1.1 ($p<0.001$) and awareness of local patient resources increased from 2.8 ± 1.0 to 4.0 ± 0.8 ($p<0.001$). There was no change in self-rated effectiveness in caring for Latino patients from pre- to post-test. Thirty-six (97 %) respondents agreed the training would help them better care for their Latino patients with chronic conditions.

CONCLUSIONS: A cultural competency training program that included local patient stories, taught self-awareness of the use of stereotypes and patient-centered communication, and provided information on local patient resources has promise in improving awareness of the use of stereotypes and knowledge of Latino cultural and health beliefs and local patient resources. Further research needs to assess the impact of this type of training on patient outcomes.

LONGITUDINAL FOLLOW UP OF A PATIENT SAFETY AND TRANSITIONS OF CARE CURRICULUM - MEDICAL STUDENTS' CONFIDENCE AND ATTITUDES Sara M. Bradley^{1,2}; Dennis Chang²; ERic Barna²; Reena Karam^{3,1}. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³Icahn School of Medicine at Mount Sinai, New York, NY. (Tracking ID #1938241)

BACKGROUND: The AAMC recognized patient safety and transitions of care as key components of high quality patient care and noted that there is a critical unmet need for medical education in these areas. This study sought to longitudinally evaluate a patient safety and transitions of care curriculum that was added to a third year Medicine -Geriatrics Clerkship using a survey of fourth year medical students during their Sub-internship. The objectives of the survey were to assess if students utilized skills taught by the patient safety and transitions of care curriculum in third year and subsequently in fourth year and whether they had increased confidence performing those skills following the curriculum. Additionally, the survey sought to evaluate fourth year students' attitudes about learning these topics, opinions on when during medical school such a curriculum is most useful, and suggestions for additional instruction related to patient safety and transitions of care.

METHODS: All fourth year medical students enrolled in a internal medicine or pediatrics Sub-internship during the first 6 months of the 2013–14 academic year were invited to participate in filling out a 20 item anonymous survey.

RESULTS: 28 students completed the survey. 65.5 % reported using skills from the patient safety and transitions of care curriculum Frequently or Almost Always. The percentage of students who were Quite or Extremely Confident in their ability to assess a patient's health literacy was 55.2 %, to provide education regarding

medications was 53.6 %, and to identify topics to review on follow-up to ensure a safe transition was 44.8 %. Students felt it was Quite or Extremely Important for medical students to learn about discharge planning (100 %), how to complete a discharge summary (96 %), how to assess a patient's health literacy (92.9 %), transitions of care (89.3 %), patient safety (85.7 %), and how to do a medication reconciliation (85.7 %). Students felt the topics of patient safety, medication reconciliation, discharge planning, transitions of care, how to complete a discharge summary, and how to work with a social worker should be taught during the third year of medical school, but that health literacy should be taught prior to the clinical clerkship years.

CONCLUSIONS: Students utilized skills taught during a patient safety and transitions of care curriculum subsequently in third and fourth year. Students felt these topics were important for medical students to learn and were appropriate to teach in the third year, including how to complete a discharge summary. Students felt health literacy should be taught earlier in the pre-clinical years.

LOOKING BEYOND THE PROSTATE: DETERMINANTS AND IMPACT OF NOCTURIA IN MIDDLE-AGED AND OLDER WOMEN Amy Hsu¹; Sanae Nakagawa²; Louise Walter¹; Stephen K. Van Den Eeden³; Jeanette S. Brown²; David Thom²; Sei Lee¹; Alison J. Huang². ¹San Francisco VA Medical Center, San Francisco, CA; ²University of California San Francisco, San, CA; ³Kaiser Permanente Division of Research, San, CA. (Tracking ID #1926776)

BACKGROUND: Nocturia is a common complaint in middle-aged and older adults presenting to primary care, and is linked to poor sleep quality, decreased mental and somatic health, falls and fractures. Among older men, nocturia is widely considered to be a consequence of prostate-related outflow obstruction. In contrast, the determinants of nocturia in older women are poorly understood and little is known about why some women suffer from nocturia but not others.

METHODS: We conducted a cross-sectional study of 2016 community-dwelling women, aged 41 to 83 years, from four racial/ethnic groups (White, Black, Asian and Latina), and enrolled in a group health delivery plan in Northern California. During home-based study visits, interviewers asked women about nocturnal voiding frequency, as well as bother and interference associated with this symptom. Other participant characteristics were examined by questionnaire, medical record abstraction, or physical examination and performance testing. Multivariable models were developed to assess for factors associated with nocturia, defined as waking two or more times to void at night. Potential predictors included demographics, gynecologic history, chronic medical conditions, medication use, and physical and mental functional status.

RESULTS: Of the 2016 participants, mean (SD) age was 56 (9) years, and over half were racial or ethnic minorities (22 % Black, 20 % Asian, 23 % Latina). Thirty-four percent reported waking to urinate at least two times per night, and 15 % reported waking to urinate at least four times per night. Of those with nocturia, 39 % reported being at least "moderately" bothered by this symptom, and 15 % reported that nocturia affected their day-to-day activities. Factors associated with nocturia in multivariable analysis included older age (OR 1.18, CI: 1.10–1.27 per 5 year increase), Black race (OR 1.86, CI: 1.39–2.50), Latina ethnicity (OR 1.36, CI: 1.02–1.83), hysterectomy (OR 1.85, CI: 1.13–3.05), vaginal estrogen use (OR 1.48, CI: 1.02–2.14), decreased mobility (OR 1.29, CI: 1.05–1.58 per 5-second increase in the Timed Up and Go test), and depression (OR 1.09, CI: 1.05–1.13 per 1-point increase on the Hospital Anxiety and Depression Scale score). The strongest predictor of being bothered by nocturia was greater frequency of nocturia (OR 2.63, CI: 2.08–3.31 per each additional nocturnal voiding episode), although 26 % of women who voided 4 or more times per night were only "slightly" or not at all bothered by this symptom.

CONCLUSIONS: Over a third of middle-aged and older community-dwelling women experience nocturia, and nearly 40 % of those with nocturia are significantly distressed by it. A variety of demographic, gynecologic, and geriatric factors are associated with nocturia in women, which suggests that a comprehensive evaluation of the patient is necessary to evaluate the risk for nocturia and tailor management to the individual.

LOW HEALTH LITERACY PREDICTS OUTCOMES AFTER SURGERY Sunil Kripalani; Jesse Ehrenfeld; Warren S. Sandberg; Yaping Shi; Catherine M. Bulka; Jonathan S. Schildcrout. Vanderbilt University, Nashville, TN. (Tracking ID #1934807)

BACKGROUND: Prior studies have shown that health literacy can affect medical outcomes, but the impact of health literacy on postoperative outcomes is not well

studied. We previously implemented routine health literacy assessment at our academic medical center, in which patients are administered a 3-item Brief Health Literacy Screen (BHLS). We determined the effect of health literacy on likelihood of hospital admission, postoperative hospital length of stay (LOS), and 30-day readmission following a wide range of surgical procedures.

METHODS: This retrospective cohort study included adult patients who completed the BHLS between 2010 and 2012 and subsequently underwent a non-emergent surgical procedure. BHLS scores ranged from 3 to 15, with lower scores indicating potential health literacy limitations. Outcomes included hospital admission after surgery, postoperative hospital LOS among admitted patients, and 30-day readmission rate. Multivariable models included adjustment for demographic characteristics, procedure type, and American Society of Anesthesiologists Physical Status Classification (ASA status).

RESULTS: A total 22,843 patients were analyzed, who had BHLS scores <9 (9 %), 9–11 (18 %), 12–14 (22 %), or 15 (51 %). Patients with a low level of health literacy were more likely to be older, male, less educated, covered by Medicare, and have higher ASA status. In unadjusted analyses, lower BHLS scores were associated with a greater likelihood of hospitalization (e.g., 65 % for BHLS<9 vs. 43 % for BHLS of 15; $p<0.001$); longer hospital LOS (e.g., 6.1 days for BHLS<9 vs. 4.1 days for BHLS of 15, $p<0.001$); and higher 30-day readmission rates (e.g., 11 % for BHLS<9 vs. 7 % for BHLS of 15, $p<0.001$). In adjusted analyses, lower BHLS scores remained significantly associated with likelihood of hospitalization and LOS, but not readmission rates.

CONCLUSIONS: Lower health literacy is associated with multiple indicators of poorer post-operative outcomes. Interventions aimed at improving surgical outcomes and health care utilization should consider the role of health literacy in patients' recovery. Postoperative outcomes by BHLS score

	3–8	9–11	12–14	15	All	p-value

LOW PATIENT TRUST IN THEIR PRIMARY CARE PROVIDER PREDICTS MEDICATION NON-ADHERENCE 12 MONTHS LATER Danielle Hessler; David Thom; Rachel Willard-Grace; Thomas Bodenheimer; Denise DeVore; Camille Prado; Ellen Chen. University of California, San Francisco, San Francisco, CA. (*Tracking ID #1934204*)

BACKGROUND: Patients' trust in their provider has been associated with medication adherence in cross-sectional studies. We examined the association between patients' trust in their primary care providers (PCPs) and medication non-adherence, in a prospective study of patients enrolled in health coaching vs. usual care.

METHODS: Participants were 441 low-income English or Spanish-speaking patients age 18 to 75 with poorly controlled type 2 diabetes, hypertension and/or hyperlipidemia at two urban federally qualified health centers. The predictor variable was patient trust in their PCP measured by the Trust in Physician Scale. Outcome measures were medication non-adherence measured by the Hill-Bone Scale (scoring range from 1 to 4, with higher score indicating greater non-adherence) and patient-reported number of days in past week medication not taken. Multivariate modeling adjusted for age, gender, language and race/ethnicity in all models. Twelve month outcome analyses adjusted for baseline adherence and intervention group.

RESULTS: Patient trust at enrollment predicted medication non-adherence at 12 months by the Hill-Bone scale (adjusted $\beta=-.15$, $p=.004$) and by patient-reported days missed taking medication in past week (adjusted $\beta=-0.17$, $p=.005$). At 12 months, patients who were in the lowest trust quartile at baseline reported missing medications in the past week twice as often as those in the highest trust quartile (mean=1.7 days vs. 0.8 days). Patients in the usual care group with lower trust at baseline were more likely to be non-adherent, by the Hill-Bone scale, than patients with higher baseline trust. In contrast, patient trust at baseline was not associated with non-adherence at 12 months for patients who received health coaching ($p=.002$ for test for interaction).

CONCLUSIONS: Patients with low trust in their provider are more likely to be non-adherent to medications up to 1 year later. Health coaching appears to attenuate the association between low trust in the PCP and non-adherence.

LOW-COST PROGRAM WITH SUSTAINED SEVEN-YEAR WEIGHT LOSS THAT CAN HELP OVERWEIGHT AND OBESE PATIENTS Nia S. Mitchell^{1,2}; Brenda Beaty^{3,4}; Ariann F. Nassel⁵; James O. Hill^{1,2}. ¹University of Colorado Anschutz Medical Campus, Aurora, CO; ²University of Colorado Anschutz Medical Campus, Aurora, CO; ³University of Colorado Anschutz Medical Campus, Aurora, CO; ⁴University of Colorado Anschutz Medical Campus, Aurora, CO; ⁵University of Alabama School of Public Health, Birmingham, AL. (*Tracking ID #1938648*)

BACKGROUND: Obesity continues to be a major problem that is difficult to treat, and there are few effective options for long-term weight loss for patients. While numerous behavioral weight loss interventions have produced significant results in

RCTs in the short term, many individuals regain most of that weight within 1 year. Similarly, commercial weight loss programs have shown significant weight loss at 1 year and some weight regain at 2 years; however, their costs are also a barrier to widespread utilization. In both cases, longer term, real-world data are lacking. Take Off Pounds Sensibly (TOPS) is a low-cost, nonprofit, peer-led weight loss program available throughout the United States. The program costs about \$90 per year, and TOPS provides educational and administrative materials. Local "chapter" meetings are held weekly, and participants are weighed privately, followed by group educational programming on topics such as healthy eating, physical activity, and behavior modification. Participants' weights are sent to the TOPS national database when they join the program and at the time they renew their annual memberships. The goals of this study were to determine the annual retention, weight change, and percentage of participants who lost a clinically significant amount of weight among TOPS members with consecutive annual renewals for up to 7 years.

METHODS: This is a non-concurrent prospective cohort analysis of longitudinal weight change of "completers" in the TOPS national database. Study participants were those aged 18 and over who joined TOPS from Jan. 1, 2005 to Dec. 31, 2011 and who consecutively renewed their annual memberships for at least 1 year. There were 213,048 potential participants, and 80,208 were included in the analysis. Retention was calculated by dividing the number of individuals who renewed their membership at a specific time point ("actual participants") by the number of potential participants who were eligible to renew their membership at that time point. Weight change was calculated using mixed-effects repeated measures models with individual random intercepts. The percentage of participants who lost 5 % or more of their initial weight was also calculated.

RESULTS: The average initial weight of "actual participants" was 99.3 kg; the average age was 58 years; and 93 % of participants were women. The results for the "actual participants" with consecutive annual renewal are depicted in the table below. It includes the annual retention, mean cumulative weight change from initial weight, and percentage of participants who lost ≥ 5 % of initial weight for all years. The retention rate was inversely proportional to the number of years of consecutive annual renewal. The one-year retention rate was 38 % and the seven-year retention rate was 6 %. The mean cumulative weight change from initial weight was directly proportional to the number of years in the program. The mean weight change for participants in the first year was -5.6 %. For those participants who remained in the program for 7 years, their mean cumulative weight change was -8.2 %. Between 47 and 62 % of participants lost ≥ 5 % of initial weight over the seven-year study period.

CONCLUSIONS: Long-term weight loss is challenging, and internists must find ways to partner with community resources to help patients manage their weight. Individuals who participated in TOPS for at least 1 year lost a clinically significant amount of weight; and those who remained in the program maintained the weight loss for up to 7 years. The weight loss in TOPS is comparable to more expensive commercial weight loss programs, and the retention rate is higher than other programs. TOPS is an effective community-based resource to which internists can refer their overweight and obese patients for weight management.

Retention, mean cumulative weight change, and percentage of people who lost $\geq 5\%$ of initial weight.

Years of eligibility (N)	Potential participants (N)	Actual participants (N)	Retention rate (%)	Mean cumulative weight change (%)	Percentage with $\geq 5\%$ weight loss (%)

MAKING HOUSING FIRST HAPPEN: ORGANIZATIONAL ACTIONS THAT AFFECT SUCCESS AMONG VA MEDICAL CENTERS IN ENDING HOMELESSNESS Stefan Kertesz^{1,2}; Sally Holmes^{4,3}; Bert White³; David E. Pollio²; Erika L. Austin^{1,2}; Joseph E. Schumacher²; Carol VanDeusen Lukas^{4,3}. ¹Birmingham VA Medical Center, Birmingham, AL; ²University of Alabama, Birmingham, AL; ³Boston VA Medical Center, Boston, MA; ⁴Boston University, Boston, MA. (Tracking ID #1929873)

BACKGROUND: In 2009, the Veterans Administration (VA) proposed to end veteran homelessness by 2015. VA has pursued this by asking VA Medical Centers (VAMCs) to advance an evidence-based housing method, Housing First, using community-based rental vouchers. Housing First (HF) prioritizes the most vulnerable individuals and expedites their placement into permanent housing without requirements for sobriety or treatment success. A massive expansion of vouchers to house ~60,000 veterans, coupled with the novel HF approach, calls on VAMCs to execute an ambitious social endeavor. This study examines organizational actions that facilitate or hinder implementation of this initiative. The study was initiated in response to VA's desire for formative feedback, and was designed in partnership with VA homeless program leaders, and other homelessness experts. VAMCs' efforts to implement HF were evaluated with the Organizational Transformation Model (OTM), which identifies key drivers of organizational change: 1) impetus for change, 2) leadership engagement, 3) management structures and processes to foster alignment and integration of efforts and sustainability. The purpose of this qualitative study was to identify variation in organizational practices and to determine if these coincided with variations in fidelity to the HF approach.

METHODS: Two expert panels, a HF site visit and literature review were used to devise scoreable constructs for OTM elements and HF fidelity. A multidisciplinary team conducted over 100 confidential interviews with VAMC leadership, middle managers, and front-line staff at 8 VAMCs. Structured narratives and consensually-derived scores (ranging from 1: not present to 4: fully present) were used to assess HF and OTM constructs at each study site. The relationship between OTM and HF scores was explored with an X-Y plot across the 8 sites.

RESULTS: There was substantial variation in HF fidelity, (mean scores ranging 2.2 to 3.2 (on a 4-point scale) and in mean OTM scores (range 2.5 to 3.7). The X-Y plot of these scores demonstrated that HF fidelity was consistently higher where OTM scores were higher, indicating that greater presence of OTM-defined organizational practices aligned with greater fidelity to HF (Figure). Examples of stronger organizational practices include: 1. Greater involvement of senior leaders in program operations; for example, support for new permanent supervisory positions and multidisciplinary teams to assure success of the HF initiative 2. Planning for sustainability of efforts; for example, transparent discussions between VAMC leadership and mid-level managers to plan services 1–2 years in advance of anticipated reductions in funding. 3. Formal process improvement exercises to overcome barriers and improve speed of placement. These were undertaken in collaboration with non-VA partners, and entailed mapping out all steps required to house a new veteran, flagging typical hitches and inefficiencies, and systematically working to remove them. Such work typically drew on Lean Management and related quality improvement principles. 4. Efforts to integrate disparate homeless initiatives to improve coordination among, for example, case management, primary care, mental health and substance abuse programs. Examples of weaker organizational practices seen in lower HF fidelity sites included: 1. Allowing program execution to become highly dependent on specific high-performing mid-level managers with few formalized linkages from VAMC senior leaders to assure material support, training, and guidance. 2. Lack of influence or collaboration between VAMC senior leadership and non-VA community partners. As is common in large organization endeavors, simple numeric performance metrics figured as important, including “percentage of units leased up” and “percentage of units going to chronically homeless veterans.” We found these played a dual role, helpfully focusing attention and creating impetus, but at times obscuring the underlying complexity of the housing endeavor itself.

CONCLUSIONS: This analysis found variations in HF fidelity that were associated with differences in the organizational practices of medical centers engaged in changing and improving the housing process for homeless veterans. These findings suggest the necessity of both strong mid-level program management together with oversight and participation by senior leadership to drive the success of a critical initiative demanding significant changes in program scope, philosophy and delivery.

MALIGNANT HYPERTENSION-INDUCED THROMBOTIC MICROANGIOPATHY: CAN IT BE DISTINGUISHED FROM THROMBOTIC THROMBOCYTOPENIC PURPURA? Sumit Daha¹; Smriti Upadhyay²; Nabin Khanal²; Vijaya R. Bhatt³. ¹Institute of Medicine, Kathmandu, Nepal; ²Creighton University Medical Center, Omaha, NE; ³University of Nebraska Medical Center, Omaha, NE. (Tracking ID #1923879)

BACKGROUND: Malignant hypertension is a common entity which affects approximately 1 % of hypertensive adults or 500,000 Americans. Albeit uncommon, it can present with microangiopathic hemolytic anemia, thrombocytopenia, and renal dysfunction (thrombotic microangiopathy, TMA), thus mimicking thrombotic thrombocytopenic purpura (TTP). While a strong clinical suspicion of TTP mandates urgent initiation of plasmapharesis, malignant hypertension is managed with antihypertensive agents. The

rarity of malignant hypertension-induced TMA prohibits our understanding of this condition.

METHODS: We reviewed reports of malignant hypertension-induced TMA published in English-language and pubmed-indexed by 30th November 2013. This included newly diagnosed case from our institution. Articles without adequate patients' information were excluded.

RESULTS: Our review included ten patients including five men, with a median age of 33 years at diagnosis. The history of hypertension was known in 50 %. All the patients had elevated blood pressure at diagnosis, with a mean arterial pressure of 159 mmHg on an average (range 123–190 mmHg). The most common presenting symptoms were neurological symptoms such as headache (80 %), blurry vision (50 %), or dizziness (20 %); or gastrointestinal symptoms such as nausea/vomiting (50 %), or abdominal pain (20 %). None of the patients had fever. In addition to significant hemolytic anemia with schistocytes (mean hemoglobin of 8.6 g/dL, range 3.8–12.6 g/dL), and elevated lactate dehydrogenase (mean of 1209 IU/L, range 135–4000 IU/L), all the patients had prominent renal dysfunction (mean creatinine of 4.3 mg/dL, range 2.4–7.6 mg/dL). However, thrombocytopenia was relatively modest (mean platelet count of $58 \times 10^3/\mu\text{L}$, range 12– $131 \times 10^3/\mu\text{L}$) and reported cases ($n=4$) had preserved ADAMTS-13 activity level (mean 69 %, range 57–83 %). All the patients received antihypertensive treatment while 40 % of them also received plasmapheresis. Of the cases that reported the particular antihypertensive agent used ($n=8$), 87 % started with intravenous agent followed by oral agent, while 13 % used oral agent alone. Following the control of blood pressure, the majority had a significant improvement in presenting symptoms (100 %), and platelet counts (90 %), however, only 60 % of the patients had significant improvement in renal function. Half of the patients needed hemodialysis. At discharge or follow up ($n=6$), the mean platelet count was $242 \times 10^3/\mu\text{L}$ (range 110– $350 \times 10^3/\mu\text{L}$) and the mean creatinine level was 2.4 mg/dL (range 1.1–4.2 mg/dL). None of the patients died or had any other complication.

CONCLUSIONS: Malignant hypertension can be managed with antihypertensive agents alone without plasmapheresis. Apart from persistent renal impairment, malignant hypertension portends overall favorable outcomes compared to TTP. Hence, it is important to be able to differentiate between the two conditions. The presence of prior history of hypertension, hypertensive end-organ damage and significantly elevated mean arterial pressure at presentation are important clues to diagnose malignant hypertension. The greater degree of renal impairment at diagnosis, relatively modest thrombocytopenia and preserved ADAMTS-13 activity can further differentiate malignant hypertension from TTP. These findings should be prospectively validated.

MAMMOGRAPHY FACILITY CHARACTERISTICS ASSOCIATED WITH TIMELY FOLLOW-UP OF ABNORMAL MAMMOGRAMS Leah S. Karliner; Celia P. Kaplan; Lin Ma; Karla Kerlikowske. UCSF, San Francisco, CA. (Tracking ID #1934230)

BACKGROUND: Delays in follow-up of abnormal mammograms are common, particularly for minority women. Delays can contribute to anxiety and women being diagnosed and treated for breast cancer at more advanced stages. We investigated whether mammography facilities vary in their timeliness of follow-up and if facility characteristics are associated with length of follow-up times.

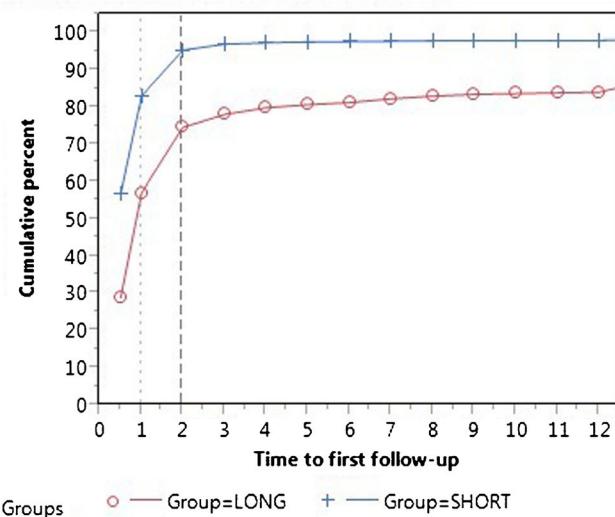

METHODS: We examined time to follow-up of abnormal mammograms collected from 2005 to 2011 for 12 facilities participating in the San Francisco Mammography Registry (SFMR). We categorized facilities based on the proportion of exams without follow-up. For abnormal mammograms with a Breast Imaging Reporting and Data System (BI-RADS) 0 assessment, we categorized facilities with $\le 15\%$ without imaging follow-up at 60-days as 'short' follow-up and $> 15\%$ as 'long' follow-up. For abnormal BI-RADS 4/5 assessments, we categorized facilities with $\le 25\%$ without biopsy follow-up at 30-days as 'short' follow-up and $> 25\%$ as 'long' follow-up. For the BI-RADS 4/5 analysis, we excluded four facilities for which the SFMR does not have complete capture of biopsy data. We then examined facility characteristics pertaining to access and staffing, communication, and population served.

RESULTS: There were 70,393 BI-RADS 0 assessments and 17,750 BI-RADS 4/5 assessments. For BI-RADS 0 assessments, the facilities in the 'short' follow-up group completed diagnostic imaging for 95.5 % of examinations at 60-days compared to 74.7 % for the 'long' follow-up group ($p < .0001$). For the BI-RADS 4/5 assessments, the 'short' follow-

up group completed biopsies for 81.6 % of examinations at 30-days compared to 60.7 % for the 'long' follow-up group ($p < .0001$). For both BI-RADS 0 and 4/5 abnormal mammogram follow-up, the 'short' follow-up facilities had higher screening and diagnostic mammography volume, more radiologists' FTE reading mammography, and shorter times to scheduling diagnostic tests compared to the 'long' follow-up facilities. More 'short' follow-up facilities contacted women directly about their abnormal result. Additionally, 'long' follow-up facilities served more vulnerable populations, including a higher proportion of minority, limited English proficient, and less educated women compared to 'short' follow-up facilities.

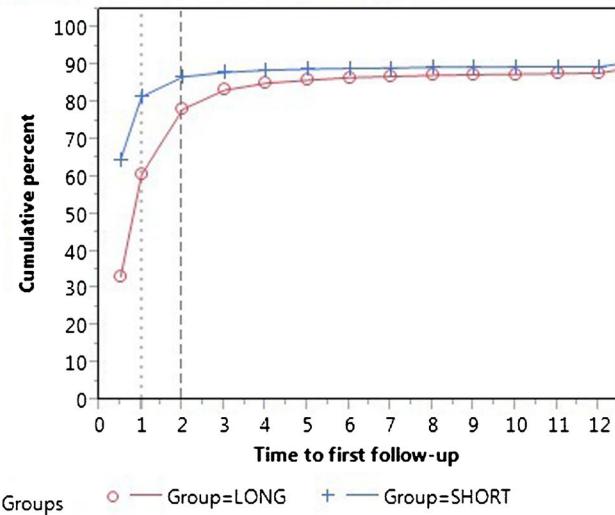

CONCLUSIONS: Clinically significant differences in follow-up of abnormal mammograms exist. Facilities serving more vulnerable populations have longer and less adequate follow-up completion that is likely related to availability of resources. Providing mammography facilities serving vulnerable populations with additional resources may decrease disparities in abnormal mammogram follow-up, and in turn timely diagnosis and treatment of breast cancer.

MAMMOGRAPHY RATES 3 YEARS AFTER THE USPSTF GUIDELINES CHANGES James F. Wharam¹; Bruce E. Landon²; Fang Zhang¹; Xin Xu¹; Steve Soumerai¹; Suzanne Fletcher¹; Dennis Ross-Degnan¹. ¹Harvard Medical School, Boston, MA; ²Harvard Medical School, Boston, MA. (*Tracking ID #1939213*)

BACKGROUND: In November 2009, the United States Preventive Services Task Force (USPSTF) changed from recommending mammography every 1–2 years among women age ≥ 40 to (1) recommending personalized screening decisions for women age 40–49 and (2) recommending screening every 2 years for women age 50–74. Our objective was to determine the impact of the updated USPSTF guidelines on mammography rates.

METHODS: We performed a retrospective before-after time-series analysis, comparing mammography rates in 2012 to those predicted based on 2005–2009 trends. The sample included 1.71–2.08 million women annually age 40–64 from a large US health plan. We assessed annual and biennial mammography rates, examining for the relative change between observed and predicted rates in 2012.

RESULTS: Among women age 40–49, adjusted annual mammography rates increased from 40.7 to 44.4 % between 2005 and 2009 and then declined to 42.3 % by 2012 (Figure 1), an estimated 9.55 % reduction (95 % CI, −10.10 % to −8.99 %) relative to the rate predicted by 2005–9 trends. Black women age 40–49 experienced a lesser decrease of 3.27 % (−5.22 % to −1.28 %, Figure 2). Yearly mammography rates among women age 50–64 increased from 48.7 to 51.3 % from 2005 to 2009 but then declined by 5.87 % (−6.32 % to −5.42 %) to 49.7 % by 2012. For biennial screening, adjusted rates in 2005–6, 2008–9, and 2011–12 among women age 40–49 were 66.4 %, 68.1 %, and 64.7 %, respectively, a 7.86 % relative reduction (−8.49 % to −7.22 %). White, Hispanic, and Asian women age 40–49 experienced similar relative reductions of −8.69 % (−9.41 % to −7.97 %), −7.33 % (−9.35 % to −5.27 %), and −9.24 % (−12.40 % to −5.98 %), respectively, whereas black women experienced a nonsignificant reduction (−1.75 %, [−3.89 % to 0.44 %]). Biennial mammography rates among women age 50–64 were 73.4 %, 74.0 %, 72.0 % in 2005–6, 2008–9, and 2011–12, respectively, a 4.39 % relative reduction (−4.89 % to −3.88 %) that was similar among white, Hispanic, and Asian women. Black women age 50–64 experienced a small increase in biennial mammography (2.90 %, [1.24 % to 4.58 %]).

CONCLUSIONS: After publication of the 2009 USPSTF guidelines, annual and biennial mammography rates declined by 4–17 % among women who were not black. Black women generally experienced lesser decreases. Reductions in biennial mammography might be an unintended consequence of the updated guidelines.

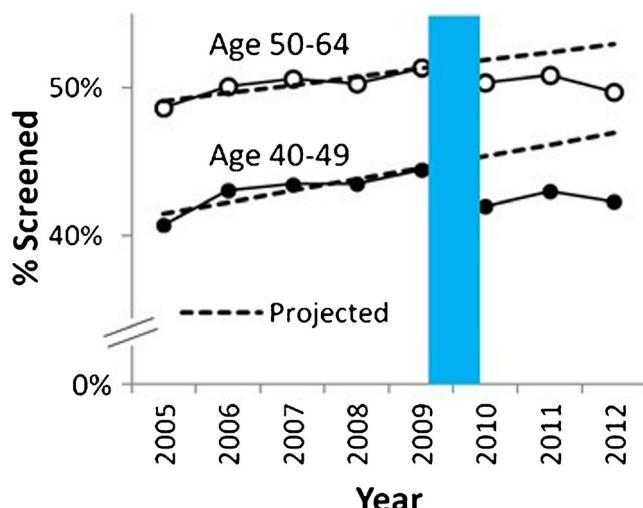

Figure 1. Annual mammography rates by age group before and after publication of the 2009 USPSTF guidelines.

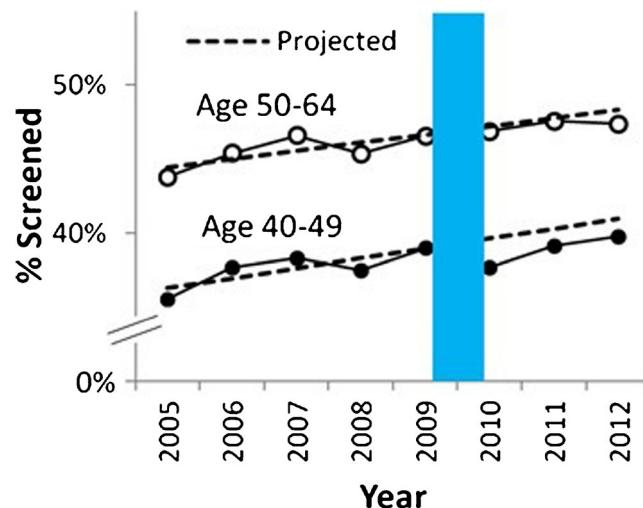

Figure 2. Annual mammography rates among black women by age group before and after publication of the 2009 USPSTF guidelines.

MANAGEMENT OF ATRIAL FIBRILLATION: A COST COMPARISON Tadeo A. Diaz Balderrama¹; Caroline Pace³; Jennifer Wright²; Shivtej Kaushal¹; Alexandria Goldin³. ¹Medical College of Wisconsin, Milwaukee, WI; ²Medical College of Wisconsin, Milwaukee, WI; ³Medical College of Wisconsin, Milwaukee, WI. (*Tracking ID #1926389*)

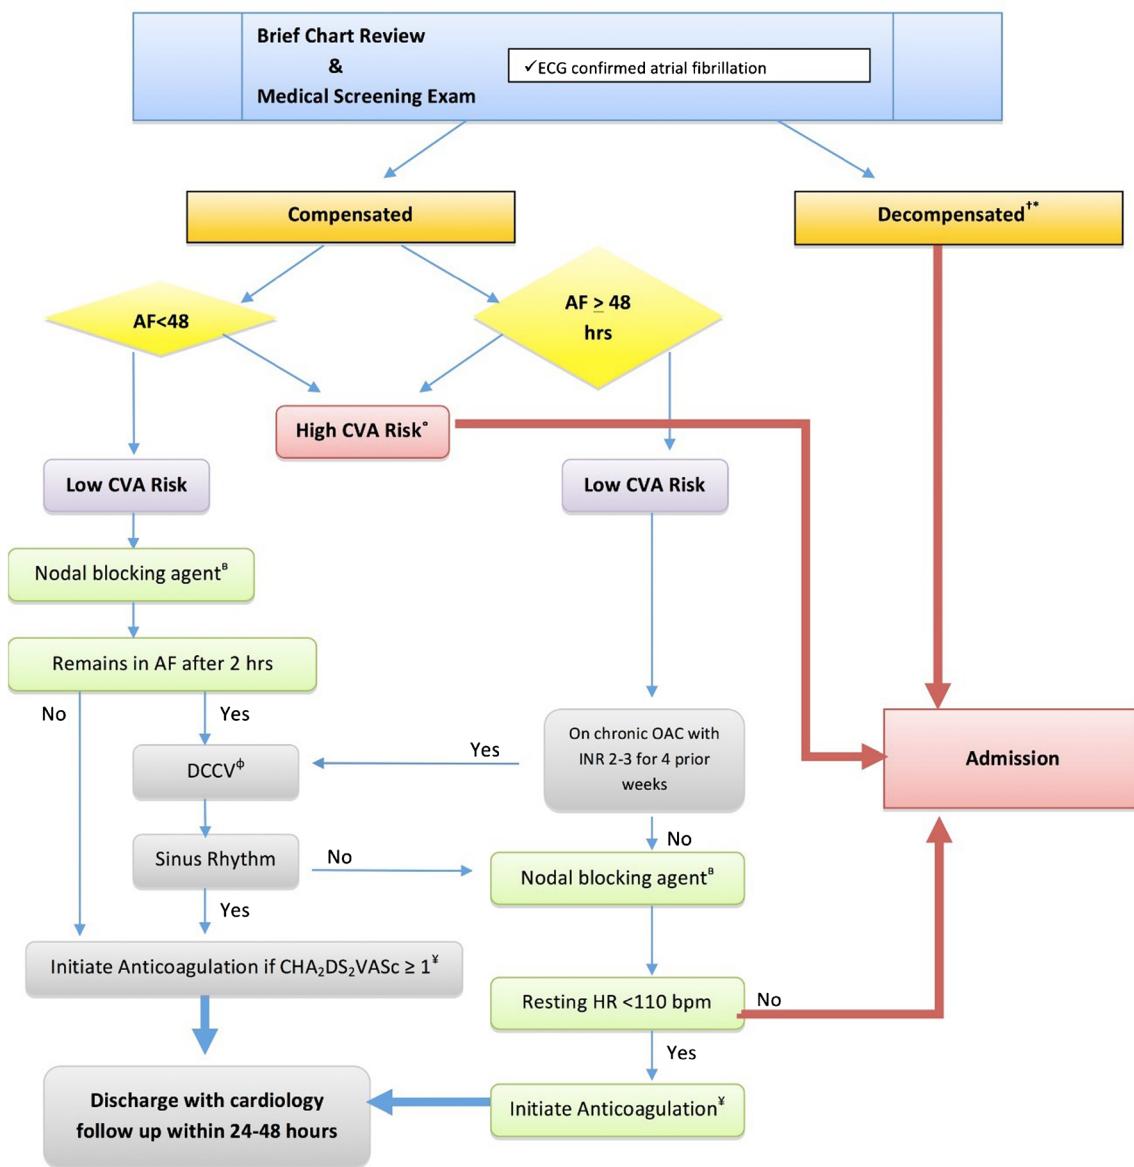

BACKGROUND: Atrial fibrillation (AF) is estimated to affect 2.7 to 6.1 million people in the United States and accounts for 350,000 hospitalizations and 276,000 emergency department (ED) visits per year. Forty-four percent of the estimated annual \$6.65 billion spent treating AF is due to inpatient care. While various methods have been used to manage AF in the ED to avoid unnecessary admissions, there is no universal standard for such management. Initial management of AF in the ED setting, with outpatient coordination of care, could decrease the number of unnecessary inpatient stays.

METHODS: All admissions to our institution from January 1, 2010 through December 31, 2010 with AF as a primary diagnosis were identified. An algorithm was created based on prior studies and current guidelines and retrospectively applied to identify the patients eligible for outpatient management. The potential cost savings were calculated by quantifying the diagnostic tests, imaging tests, inpatient days of stay and the consults which were documented during the patients stay.

RESULTS: Fifty-seven out of 120 patients would have qualified for ED management. Patients who qualified for ED management were younger (59 years vs 70.8 years, $p < 0.0001$), had presenting complaints of palpitations ($p < 0.05$) and had lower CHADS2 ($p < 0.0001$) and CHA2DS2VASC scores ($p < 0.0001$). Patients mean length of stay in the hospital was 2.33 days and after factoring inpatient and ED costs along with potential outpatient follow up costs, the mean cost savings per patient was estimated at \$2495.65.

CONCLUSIONS: An algorithm to guide ED management of AF in appropriate patients may reduce the need for hospital admissions and likely result in overall healthcare cost savings. Further evaluation of outpatient costs of care for the patients who qualify for outpatient management will help determine the feasibility of such an approach.

MASSACHUSETTS HEALTH CARE REFORM REDUCED RACIAL/ETHNIC DISPARITIES IN ELECTIVE PERCUTANEOUS CORONARY INTERVENTION AND CORONARY ARTERY BYPASS GRAFT SURGERY Amresh D. Hanchate^{1,2}; Steven M. Bradley^{3,4}; Alok Kapoor²; Danny McCormick⁵; Karen E. Lasser²; Chen Feng²; Nancy R. Kressin^{1,2}. ¹VA Boston Healthcare System, Boston, MA; ²Boston University School of Medicine, Boston, MA; ³VA Eastern Colorado Healthcare System, Denver, CO; ⁴University of Colorado, Denver, Denver, CO; ⁵Cambridge Health Alliance, Cambridge, MA. (Tracking ID #1937646)

BACKGROUND: Percutaneous coronary intervention (PCI) and coronary artery bypass graft (CABG), arguably the most commonly examined surgical procedures in the literature on racial and ethnic disparities, are documented to be used less often among racial/ethnic minorities. The differences in use have been associated with factors other than clinical need. Large-scale insurance coverage expansions, such as the Massachusetts (MA) reform of 2006 and the Affordable Care Act of 2010, have the potential to reduce disparities in access to health care, particularly outpatient care. Thus, they provide an unique quasi-experimental setting to examine the causal impact of insurance coverage expansion on disparities in use of elective PCI and CABG.

METHODS: We applied a difference-in-differences design to estimate the impact of MA reform on use of elective and non-elective PCI and CABG among adults aged 40

to 64 (those most at risk for these procedures among the target beneficiaries of reform) by race/ethnicity (Whites, Blacks and Hispanics). We estimated population rates of procedure use (# procedures per 100,000 census population) during the 2 years prior to the start of reform (7/1/2006) and the 2 years following coverage expansion (1/1/2008). To isolate the impact of reform, we adjusted for secular changes unrelated to reform based on a comparison of the pre-post change in the target subpopulation (MA residents aged 40 to 64) with corresponding changes among (a) residents of three comparison states (New Jersey, New York and Pennsylvania) aged 40 to 64, and (b) residents of MA aged 65 and older. We obtained comprehensive counts of elective and non-elective PCI and CABG procedures from 2004 to 2010 state discharge data files. Population counts were obtained from the census data files. Stratifying the population by race/ethnicity, age and sex, we estimated Poisson regression models with fixed effects for state and time.

RESULTS: During the pre-reform period the total combined numbers of elective PCI and CABG procedures, by race/ethnicity, were: 11,919 (Whites), 227 (Blacks) and 251 (Hispanics). Pre-reform procedure rates (# procedures per 100,000) were significantly lower among Blacks (71) and Hispanics (80) compared to Whites (139). There was a secular decrease in overall rates of elective PCI and CABG, with a larger decrease among the target cohort of MA residents aged 40 to 64 (-41 %) than among comparison-state residents aged 40–64 (-28 %) and MA residents aged 65 and older (-32 %). Adjusted for secular trends, MA reform was associated with an increase in elective procedures among Blacks (7 %, 95 % confidence interval [CI]=[3 %, 11 %]) and Hispanics (4 %, 95 % CI=[2 %, 6 %]), but a decrease among Whites (-7 %, 95 % CI=[-8 %, -6 %]). For non-elective PCI and CABG procedures, MA reform was associated with no change among Whites, Blacks and Hispanics.

CONCLUSIONS: MA health reform may have increased the use of elective PCI and CABG among Blacks and Hispanics, thereby indicating possible improved access to outpatient care and reduction of disparities. Despite a sizable secular decrease in procedure use among all subpopulations, procedure use may have increased among minority groups with previously unmet need or with newly identified need. While this finding might suggest similar potential for ACA nationwide, the role of other facilitating factors, such as adequate provider availability, also need to be taken into account.

MASSACHUSETTS HEALTH REFORM WAS ASSOCIATED WITH MOVEMENT OF INPATIENT CARE FROM SAFETY-NET TO NON-SAFETY-NET HOSPITALS AMONG FREQUENTLY HOSPITALIZED PATIENTS Karen E. Lasser^{2,4}; Chieh Chu²; Danny McCormick³; Amresh D. Hanchate^{1,2}; Nancy R. Kressin^{1,2}. ¹VA Boston Healthcare System, Boston, MA; ²Boston Medical Center/Boston University School of Medicine, Boston, MA; ³Cambridge Health Alliance/Harvard Medical School, Cambridge, MA; ⁴Boston University, Boston, MA. (*Tracking ID #1928396*)

BACKGROUND: Quality of care may be higher at non-safety-net (non-SNH) hospitals relative to safety-net hospitals (SNH), and non-SNHs may thus be more attractive to patients with freedom to choose where they receive care. Massachusetts (MA) health reform enabled previously uninsured patients the choice to transfer their care from SNH to non-SNH. Prior studies have not examined the effect of MA health reform on individual patient movement from SNH to non-SNH for inpatient care. We hypothesized that changes in patient movement toward non-SNHs would be greater in MA than in comparison states without expanded insurance coverage.

METHODS: We used 2004–2009 inpatient discharge data from MA, New York (NY), and New Jersey (NJ), examining adult hospitalizations for all causes (except obstetrical diagnoses). Defining pre-reform (9/1/2004 to 6/30/2006) and post-reform (1/1/2008 to 9/30/2009) periods, our study examined adult patients with >=2 hospitalizations in each period. In each state, we identified a cohort of patients as “SNH users,” patients for whom all hospitalizations during the pre-reform period were at a SNH. We compared movement from SNH to non-SNH (defined as >=1 hospitalization in a non-SNH in the post-reform period) among patients age 18–64 (those most affected by health reform) and those age >= 65 in MA to movement among patients age 18–64 and those age >=65 in comparison states. We also analyzed movement rates according to race/ethnicity among patients age 18–64, to assess disparities in such changes. We used a difference-in-differences design to identify the post-reform change in MA, adjusted for secular changes unrelated to reform, and adjusted for the effects of factors known to affect SNH use, including race/ethnicity, income, insurance, and nearest hospital type.

RESULTS: In MA, of 10,308 patients, 6924 remained at a SNH in the post-reform period, and 3384 (32.8 %) moved to a non-SNH. In comparison states, of 30,242 patients, 18,584 remained at a SNH in the post-reform period, and 11,658 (38.5 %)

moved to a non-SNH. The difference in movement from SNH to non-SNH was greater among MA adults age 18–64, relative to MA elderly adults, than between non-elderly adults and elderly adults in comparison states (difference-in-difference adjusted odds ratio [AOR] 1.11, 95 % confidence interval [CI], 1.0–1.2, *p*=0.04). In MA, there was a significant increase in movement to non-SNH for patients with a diagnosis of pneumonia (AOR 1.8, 95 % CI 1.1–3.0), but not for CHF, CAD, asthma, or diabetes. Relative to whites, there was a trend towards less movement to non-SNH for MA Hispanics relative to Hispanics in comparison states (AOR 0.8, 95 % CI 0.7–1.0, *p*=0.06). Relative to patients with private insurance, patients who were self-pay (in any state) were less likely to move to a non-SNH (AOR 0.4 95 % CI 0.3–0.4).

CONCLUSIONS: Coverage expansion in MA was associated with increased movement from SNH to non-SNH among a subset of 3384 very sick patients. While anticipation of such movement has been used to justify funding cuts to SNH in MA, other studies that have examined the universe of inpatient care utilization have found very little net shift in inpatient volumes between SNH and non-SNH.

MATCH RATES IN PRIMARY CARE SPECIALTIES FOR MEDICAL STUDENTS WHO PARTICIPATED IN A STUDENT-FACULTY COLLABORATIVE PRACTICE Charlotte E. Ward¹; Emma C. Jeffries¹; Marya J. Cohen¹; Rebecca Berman². ¹MGH, Boston, MA; ²Brigham and Women's Hospital, Boston, MA. (*Tracking ID #1938257*)

BACKGROUND: It is becoming increasingly difficult for patients to find primary care physicians (PCPs) in the United States. The Medicaid expansion will extend coverage to 30 million new patients, many of whom will likely need a PCP. It is important, therefore, to attract a greater number of medical students to the field of primary care and to better understand factors that contribute to student career interests. The Crimson Care Collaborative (CCC), a series of 5 student-faculty collaborative practices, aims to give students hands-on practical experience in understanding innovation in primary care clinics across the Harvard Medical School network. Since the opening of CCC in 2010, we have had 500 students participate in CCC, including 70 who have since graduated. The aim of our study was to compare primary care residency match rates of CCC students to those who did not participate in CCC.

METHODS: Harvard Medical School (HMS) residency match lists from 2010 to 2013 were compared to CCC rosters over the same time period. Internal medicine, primary care, OB/GYN, family medicine and pediatrics match rates of CCC participants were compared to those of non-CCC participants using Chi-square tests.

RESULTS: Out of 500 students who participated in CCC, 70 students graduated during 2010–2013. During the same time period, 556 non-participants in CCC graduated. Internal medicine match rates were higher among CCC participants compared with non-CCC participants (32.9 %, vs. 19.4 %, *p*=0.009). Match rates for internal medicine programs with a focus on primary care were higher among CCC participants compared with non-CCC participants (8.6 %, vs. 3.2 %, *p*=0.05). Family medicine match rates were higher among CCC participants compared with non-CCC participants (8.6 %, vs. 3.6 %, *p*=0.05). OB/GYN match rates were lower among CCC participants compared with non-CCC participants (2.9 %, vs. 4.7 %, *p*=0.49). Pediatrics match rates were lower among CCC participants compared with non-CCC participants (8.6 %, vs. 9.2 %, *p*=0.87). Among all five primary care fields combined, match rates were higher among CCC participants compared with non-CCC participants (61.4 %, vs. 40.5 %, *p*=0.0008).

CONCLUSIONS: Among a group of medical students who participated in a primary care based student-faculty collaborative clinic, primary care residency match rates were higher in comparison to those who did not participate. As the demand for primary care services grows, so does the need for programs such as CCC that are designed to expose greater numbers of medical students to primary care careers. We plan to continue data evaluation to see whether this residency match trend strengthens over time.

MEDICAL DECISION MAKING IN A PRIMARY CARE CLINIC Jeffrey L. Jackson^{1,2}; Patrick G. O'Malley²; Dorothy Becher². ¹Zablocki VAMC, Milwaukee, WI; ²Uniformed Services University, Bethesda, MD. (*Tracking ID #1921916*)

BACKGROUND: Shared medical decision is a goal of most health care delivery systems. Our purpose was to develop a tool to assess patient desire for shared medical decision making and the impact of patient assessment of shared decision making on patient outcomes.

METHODS: In a pilot study, we asked patients to rate the type of shared decision making they desired on a visual analog scale prior to their visit. One end was

anchored by a desire for the provider to make all the decisions, in the middle was equal decision making between patients and providers and at the other end was a desire for the patient to make all the decisions. Immediately after the encounter, patients and providers were asked to rate the shared decision making that occurred using this same scale. Patient outcomes included trust (Trust-7), satisfaction (Rand-9), adherence (pill count). Additional measures included health literacy, functional status, depression (PHQ-9) and somatization (PHQ-15). Visits were audiotaped and coded using RIAS.

RESULTS: Among 120 ambulatory patients, most expressed a desire for equal decision making (58 %), 19 % wanted the provider to be more dominant and 23 % wanted the patient to be more dominant. At the extremes, only 3 % wanted the provider to make all the decisions and 2 % wanted to personally make all decisions. After the encounter, patients reported 57 % of decision-making in encounters were equally shared, 31 % had provider dominance and 12 % patient dominance. When the patient desires and patient ratings of encounters were compared, 19 % reported more patient dominance than desired, 51 % reported perfect match between the degree of shared decision making experienced and desired; 30 % reported more provider dominance. However, there was no relationship between discordance of decision making and satisfaction, trust or medication adherence. Providers reported some degree of dominance in 50 % of encounters, equal decision making in 26 % and patient dominance in 24 %. There was little agreement between patient and provider perception of dominance during the encounters; providers reporting twice as much patient dominance as reported by patients. There was also no relationship between the difference in perception by patients and doctors about shared medical decision making and patient trust, satisfaction or adherence. Finally, objective assessment with RIAS found no relationship between patient or provider perception of the degree of shared decision making and provider dominance during the encounter.

CONCLUSIONS: About half of encounters had a good match between the patient's expressed desired style of decision making and the decision making style they experienced. Patients reported that a third of encounters had greater provider dominance than desired, consistent with provider reports of dominating decision making in nearly half of encounters. Providers reported twice as much patient decision making dominance as reported by patients. Interestingly, there was no relationship between desired or perceived style of decision making and patient outcomes, including trust, satisfaction and medication adherence. In addition, there was a lack of agreement between RIAS dominance assessment and either patient or provider dominance ratings.

MEDICAL SCHOOL CHARACTERISTICS AND STUDENT DESIRE TO WORK WITH THE UNDERSERVED *Alex Montero^{1,2}; Rebecca Brown^{2,3}; Tracy V. Fulton^{2,1}; Nicole Szabo⁴; Thaidra Gaufin⁴; Sadhana Rajamoothi⁴; Eileen Moore^{1,2}. ¹Georgetown University Hospital, Washington D.C., DC; ²Georgetown University School of Medicine, Washington D.C., DC; ³Beth Israel Deaconess Medical Center, Boston, MA; ⁴Georgetown University, Washington D.C., DC. (Tracking ID #1939627)*

BACKGROUND: Physician shortages among urban, underserved patient populations are a pressing and complex problem. These populations often have large low-income, minority and immigrant populations in great need of medical services. Prior literature suggests that the shortage of physicians in urban underserved areas is due to complex factors including structural aspects of these communities (barriers to medical access, poverty, race, and cultural barriers) and determinants of medical student career choice in regards to primary care (i.e. debt burden). In response to the declining numbers of medical students entering primary care, there has been increased effort by medical schools to stimulate student interest in both serving the underserved and pursuing primary care careers with mixed success. The aim of this study was to explore possible associations between students interested in serving vulnerable urban populations and medical school characteristics (both curricular and non-curricular) which may increase interest in working with the urban underserved.

METHODS: Design: Cross sectional survey. Methods: We sent an on-line survey to 40 U.S. medical schools in close proximity to urban populations. The survey was sent to medical school deans, relevant student club leaders, and social contacts of the authors known to be at the eligible schools. Approximately 4,000 students were eligible to take the survey. Our response rate was 1,012 medical students. The survey queried students about demographic

information, relevant school curricular elements, and their opinions about underserved urban populations; our independent variables were constructed from these domains. A priori, we constructed two main outcome variables: 1) "any interest"—students with any career interest in working the underserved; 2) "strong interest"—students with clear career goals of working with the underserved. We conducted univariate and multivariate analyses with both outcome variables.

RESULTS: With regard to "any interest" students, univariate analysis revealed significant associations with school year (more interest in pre-clinical students, $p=0.01$), presence of student free clinic (more interest in schools with student free clinics, $p=0.00$), and presence of required community service curriculum (more interest in schools with community service curricula, $p=0.06$). Of note, race/ethnicity was not significant. In regards to "strong interest" students, univariate analyses revealed significant associations with political affiliation and race/ethnicity. With regard to "any interest" students, multivariable analyses revealed that only the presence of a student free clinic remained significantly associated with the outcome variable. With regard to "strong interest" students, multivariable analyses revealed that political affiliation and school year remained significantly associated with the outcome variable.

CONCLUSIONS: Student run free clinics (SRFC) are an informal, non-required curricular element present in the majority of US medical schools. However, our study indicates that SRFC are the only medical school characteristic that is independently associated with students having any interest in working with the underserved. For more committed students, other non-curricular elements are independently associated with a desire to work with the underserved.

MEDICAL STUDENTS' ENGAGEMENT IN COLLABORATIVE COMMUNICATION DURING AN INTERPROFESSIONAL STANDARDIZED PATIENT ENCOUNTER *Sandra K. Oza; Maria A. Wamsley; Christy K. Boscardin; Joanne Batt; Karen E. Hauer. University of California, San Francisco, San Francisco, CA. (Tracking ID #1939640)*

BACKGROUND: Effective and collaborative communication is essential for the provision of high-quality patient care. As members of healthcare teams, medical students frequently interact with a variety of health professionals while providing patient care. However, the nature of medical students' communication with other health professionals has not been widely studied. We explored medical students' engagement in collaborative communication with another health professional during a simulated patient care encounter.

METHODS: We developed a conceptual framework of collaborative communication based on theoretical explanations of collaboration and the empirical research on nurse-physician communication. This framework included constructs related to role identification, information exchange, decision-making, and interpersonal exchanges. We then applied this framework to an analysis of a purposive sample of 60 medical students. The study setting was an objective, structured clinical examination (OSCE) case in which students communicated with a standardized nurse (SN) and standardized patient. Using directed qualitative content analysis, we analyzed medical student dialogue with the SN for the elements of collaborative communication included in our framework. We examined differences in collaborative communication by student performance level as defined by the SN global satisfaction rating.

RESULTS: We found that across encounters, medical students engaged in all elements of collaborative communication in our framework. All students in our sample exchanged interpersonal comments with the SN, and all but one identified

their role to the SN. Students who received higher global satisfaction ratings by the SN were more engaged in bidirectional information exchange with the SN (the student both sought information from the SN and shared information with the SN) and joint decision-making with the SN (the student sought the SN's input into a care plan for the standardized patient).

CONCLUSIONS: We found that medical students engaged in all of the communicative elements that comprised our conceptual framework of collaborative communication in a simulated encounter. Highly rated students were more likely to engage in bidirectional information exchange and joint decision-making, suggesting that these communication elements may be particularly important for collaborative communication. Our study provides support for the further development and use of this conceptual framework of collaborative communication for assessing students' collaboration with interprofessional colleagues. These study findings suggest that curriculum development in interprofessional collaborative communication could be framed around this conceptual framework, with emphasis on information exchange and joint decision-making with other healthcare professionals.

MEDICATION ACCURACY AND ADOPTION OF A COMPUTERIZED PHYSICIAN HANOFF TOOL Alex Montero; Millicent Yee. Georgetown University Hospital, Washington, DC. (*Tracking ID #1940222*)

BACKGROUND: Communication failures and suboptimal patient handoffs are major factors contributing to adverse patient safety events. Unstructured, non-standardized physician handoffs in inpatient settings have been shown to be associated with medical errors and adverse patient safety events. Manually populated, templated written handoffs have been shown to frequently contain medication errors of omission and addition of high risk medications such as anticoagulants and narcotics. Computerized physician handoff tools (CHTs) have been widely adopted to optimize patient handoffs but remain understudied with regard to patient safety outcomes, and no study has assessed the impact of CHT on the medication accuracy of written physician handoffs. In June of 2013, a multiphase implementation of a CHT (CORES Smart Handoffs) was started on house staff teaching services throughout Georgetown University Hospital (GUH). We report on the impact of the adoption of a CHT on medication accuracy of physician handoffs on at an academic medical center.

METHODS: Design: prospective observational cohort study. Methods: On June 1st, 2013 CORES Smart Handoffs was implemented on four of six resident teaching teams at GUH. Implementation of CORES on two resident teaching teams was delayed by 6 weeks. Written signouts of all teaching teams was collected on randomly selected days for 6 weeks starting on June 1st, 2013. Medication lists from written sign-outs were compared to "gold standard" lists obtained from GUH's clinical information systems to ascertain the accuracy of each medication listed on the written sign-outs. Medication errors per written sign-out were quantified and characterized as omissions/additions and according to a standardized severity scale. The error rate of CORES generated medication lists was compared with the error rate of manually populated medication lists. The main outcome was the medication error rate per written signout. The independent variable was the source of the medication list (CORES medication lists vs. manually populated medication lists). Student t-test analysis was employed for all analysis.

RESULTS: Results: The mean rate of medication errors was significantly lower for both omissions and additions for CORES generated written sign-outs. This was true for both high risk and low risk medications. The average number of medications per written sign-out went up significantly with the CORES generated sign-outs.

CONCLUSIONS: Medications listed on a CHT generated written sign-outs were clearly more accurate than those listed on a manually populated and templated written sign-outs. However, the marked increase in medications listed on a CHT written sign-out was concerning for a "clutter" effect that may limit the positive impact of more accurate medication lists on patient safety. The impact of the adoption of a CHT on preventable medication errors needs to be assessed to confirm the safety benefit of more accurate medication lists on CHT generated written sign-outs.

Rate of Omission Errors on Written Sign-outs

	Mean per patient sign-out	P Value < 0.0001
CHT Generated Sign-outs	0.2	
Non-CHT Generated Sign-outs	2.197	

Rate of Commission Errors on Written Sign-outs

	Mean per Patient Sign-out	P Value < 0.005
CHT Generated Sign-outs	0.148	
Non-CHT Generated Sign-outs	0.299	

MEDICINE ATTENDING ROUNDS: FREQUENCY OF OBSERVED TEACHING BEHAVIORS AND LEARNERS' PERCEPTIONS Frank W. Merritt¹; Allan V. Prochazka^{1,2}; Eva M. Aagaard¹; Chad Stickrath^{1,3}. ¹University of Colorado School of Medicine, Denver, CO; ²Denver Veterans' Affairs Medical Center, Denver, CO; ³Denver Veterans' Affairs Medical Center, Denver, CO. (*Tracking ID #1938268*)

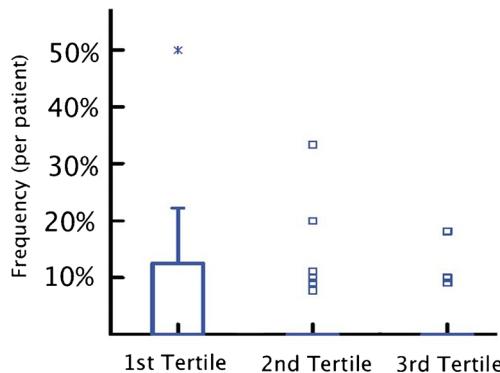

BACKGROUND: Daily rounds with the attending physician are a central component of medical education for both residents and students in teaching hospitals. However, time for education in this setting can be limited by the demands of patient care. Little is known about the frequency and effectiveness of teaching behaviors on rounds in the current era.

METHODS: We performed a cross-sectional study of attending rounds on general medicine inpatient wards at 4 teaching hospitals. Trained observers accompanied teams on rounds and recorded frequency of educational activities performed by attendings. Students and residents present on the observed day were asked to rate the attending using a Likert scale (1 = strongly disagree to 4 = strongly agree) in response to the statement "Overall, effective teaching occurred on rounds today." The effectiveness of 9 specific teaching behaviors was similarly assessed. We compared the frequency of the specific teaching behaviors with their perceived efficacy. In addition, we grouped attendings into tertiles based on perceived overall teaching effectiveness. Then, we compared the frequency of each observed teaching behavior amongst the three tertiles of attendings using the Kruskal Wallis test.

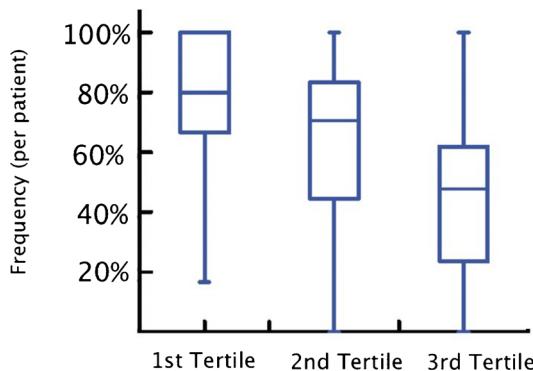

RESULTS: Overall, 90 rounding episodes were observed including 83 attendings, 279 trainees, and 807 patient encounters. The highest-scoring tertile of attendings scored an average of 3.6 on overall teaching effectiveness, the middle 2.2, and the lowest-ranked 1.2. The highest-ranked attendings performed an average of 2.4 teaching behaviors per patient encounter versus 1.5 in the lowest-scoring group. Significant differences also occurred in the frequency of addressing questions about the patient care plan (77.6 % vs 65.9 % vs 47 %, p=0.003), providing feedback (31.5 % vs 10 % vs 0.5 %; p=0.001), and teaching about learner-identified topics (8.0 % vs 2.2 % vs 1.9 %; p=0.018). There was no significant difference in the frequency of teaching general medical topics, specific evidence-based medicine literature, history-taking, physical examination, or oral presentation skills. The average rounding time per patient was approximately 13 min in all 3 groups.

CONCLUSIONS: We found a range of learner satisfaction with teaching from medicine attendings, which may be partially explained by variations in the number and types of teaching behaviors performed. Importantly, the best-ranked teaching attendings performed almost twice as many total teaching behaviors per patient without spending more time rounding. Furthermore, the teaching behaviors that distinguished the highest from the lowest performing attending groups were patient-oriented, such as addressing questions about the patient care plan, and learner-centered, such as giving feedback and teaching about learner-identified topics. In the future, investigators should assess how top-rated attendings are able to perform more teaching behaviors in the same amount of time per patient and whether faculty development efforts aimed at increasing the frequency of patient-oriented and learner-centered teaching behaviors result in better teacher ratings.

Teaching Learner-Initiated Topic

Patient-Care Question Addressed

Tertiles of attendings are grouped by student and resident rankings of teaching effectiveness (on the particular rounding day the was observed). The boxes represent 25 %–75 % with the thick middle line representing the median. The mean is included in the text but not pictured.

METABOLIC RISK FACTORS AND GENETIC RISK PARTIALLY MEDIATE THE RISK OF TYPE 2 DIABETES CONFERRED BY PARENTAL DIABETES HISTORY IN THE FRAMINGHAM HEART STUDY Sridharan Raghaban^{1,2}; Bianca Porneala¹; Josée Dupuis³; James B. Meigs^{1,2}. ¹Massachusetts General Hospital, Boston, MA; ²Harvard Medical School, Boston, MA; ³Boston University School of Public Health, Boston, MA. (*Tracking ID #1925986*)

BACKGROUND: Family history of type 2 diabetes mellitus (T2D) is a strong determinant of an individual's risk of developing the disease. The effect of parental history is typically divided into genetic heritability and the influence of familial environment; the advent of genetic testing for chronic disease risk has made it possible to assess the exchangeability of measurable indices of environmental and genetic risk for directly ascertained family history. Recent work suggests that only 15–20 % of the risk of T2D associated with parental history is mediated by the combination of common genetic markers associated with diabetes and lifestyle factors including diet and physical activity. We examined whether metabolic risk, as represented by indices of beta-cell function and insulin resistance, could further explain familial T2D risk. We hypothesized that metabolic risk factors substantively mediate T2D risk associated with parental diabetes history.

METHODS: Metabolic risk was estimated using corrected insulin response (CIR, Table 1) to represent beta-cell function, and homeostatic model assessment—insulin resistance (HOMA-IR, Table 1) and a score of 0 to 4 metabolic syndrome components (MSS; one point each for increased waist circumference, elevated systolic or diastolic blood pressure, elevated triglycerides or low high-density lipoprotein, and impaired fasting glucose) to represent insulin resistance. We studied initially non-diabetic participants of the Framingham Offspring Study and tested risk across 0 ($n=1965$), 1 ($n=370$), or 2 ($n=26$) parents with T2D using logistic regression of incident T2D (265 incident cases over median follow-up of 13 years) in models that accounted for sibling correlation and adjusted for age, sex and a count of 62 common T2D genetic risk alleles. The proportion of T2D risk mediated by metabolic factors was estimated by comparing the logistic regression coefficients for parental history with and without adjustments for CIR, HOMA-IR, and MSS (% mediated = $-\beta_{adj} / \beta_{unadj}$).

RESULTS: HOMA-IR and MSS, but not CIR, were statistically significantly correlated with a greater number of parents with T2D at baseline (Table 1). The combination of metabolic risk factors and common T2D genetic risk alleles mediated 18.7 % of incident T2D risk associated with parental history of diabetes, corresponding to a reduction in the odds ratio for incident diabetes from 2.13 to 1.84 per diabetic parent after inclusion of metabolic and genetic covariates (Table 2). After adjusting for genetic risk, metabolic factors mediated 11 % of parental history independent of genetic risk (odds ratio reduction from 1.99 to 1.84; Table 2).

CONCLUSIONS: Similar to prior work examining lifestyle factors and BMI, metabolic factors and genetic risk substantively but partially mediate T2D risk due to family history. A significant proportion of familial T2D risk, however, remains unexplained by metabolic and genetic factors. We conclude that ascertainment of family history remains an important aspect of diabetes risk assessment.

MINDFULNESS BASED COGNITIVE THERAPY VERSUS A HEALTH ENHANCEMENT PROGRAM FOR TREATMENT RESISTANT DEPRESSION: A RANDOMIZED CONTROLLED TRIAL Mitchell D. Feldman¹; Erin P. Gillung²; Kevin Delucchi³; Stuart J. Eisenhardt⁴. ¹UCSF, San Francisco, CA; ²UCSF, San Francisco, CA; ³UCSF, San Francisco, CA; ⁴UCSF, San Francisco, CA. (*Tracking ID #1927292*)

BACKGROUND: Major depressive disorder (MDD) is the leading cause of disability in the developed world, yet broadly effective treatments remain elusive. Up to 40 % of patients are unresponsive to at least two trials of antidepressant medication and are thus labeled as having treatment-resistant depression (TRD). There is an urgent need for cost-effective, non-pharmacologic, evidence-based treatments for TRD. Prior research has demonstrated that Mindfulness-Based Cognitive Therapy (MBCT) is an effective treatment for major depression, but it has not been previously studied in patients with TRD. MBCT is based on a combination of mindfulness meditation with elements of cognitive behavior therapy. The purpose of this study was to evaluate whether (MBCT) is an effective augmentation of antidepressants for adults with MDD who failed to respond to standard pharmacotherapy.

METHODS: Randomized controlled trial of MBCT versus an active comparator condition, the Health-Enhancement Program (HEP), comprised of physical fitness, nutrition and music therapy. Participants were age 18 years and older with TRD who had failed to respond to two or more antidepressant trials. All participants were taking antidepressants at the time of enrollment. One hundred seventy three participants were recruited from primary care and other settings and randomly assigned to 8 weekly group sessions of MBCT or HEP. Treatment response and depression remission rates were assessed at weeks 4 and follow-up weeks 8, 24, 36 and 52 using the clinician-rated Hamilton Depression Severity Rating Scale (HDRS). HDRS response and remission rates and mean HDRS total scores were compared between treatment conditions using a GEE-based repeated measures model accounting for clustering by cohort. The models included treatment condition, assessment point, and their interaction.

RESULTS: Significant improvement was seen in rates of response ($p=<.001$), remission ($p<.01$), severity ($p<.001$) and percent reduction in severity score ($p<.01$). No significant differences between treatment groups were found. A significant condition-x-time interaction was observed for both the severity score and percent reduction indicating that the MBCT continued to improve at Week 8 while the improvement in the HEP condition leveled off.

CONCLUSIONS: Both MBCT and HEP produced improvement in patients with treatment-resistant depression over 8 weeks. While the differences between conditions were not statistically significant, differences in course of improvement suggests differences in long-term follow-ups (underway) may be significant.

Clinical Characteristics of Adults with Treatment-Resistant Depression Receiving Mindfulness-Based Cognitive Therapy (MBCT) or the Health Enhancement Program (HEP)

Variable	MBCT (N=87)		HEP (N=86)	
	Mean	SD	Mean	SD
Age at depression onset	18.8	10.9	3.5	13.2
Total # depressive episodes (months)	3.6	2.6	78.5	2.4
Length of current depressive episode (months)	84.4	119.5	17.4	93.5
HAM-D Score	18.3	3.4		3.5
Single episode (%)		20.7	22.1	
≥3 lifetime episodes		62.2	58.0	
Previous treatment for depression (%)				
Hospitalization		16.1	18.6	
Suicide Attempt		19.0	20.5	
Recruitment Source %				
GIM		34.5	36.1	
Psychiatry Clinic		43.7	39.5	
Community		24.4	24.4	

HAM-D = Hamilton Depression Rating Scale

Depression Outcomes over Time for Adults with Treatment-Resistant Depression Receiving Mindfulness-Based Cognitive Therapy (MBCT) or the Health Enhancement Program (HEP)

Outcome Variable	MBCT Group (N=87)		HEP Group (N=86)	
	Mean ± SD		Mean ± SD	
HAM-D Mean Score				
Baseline	18.3±3.4		17.4±3.5	
Week 4	13.8±4.7		12.8±4.3	
Week 8	11.4±4.9		12.5±5.0	
HAM-D Percent Reduction				
Week 4	0.23±0.20		0.24±0.24	
Week 8	0.36±.25		0.25±0.27

MISSED OPPORTUNITIES: A THOROUGH CHART REVIEW OF NEWLY DIAGNOSED HIV POSITIVE PATIENTS IDENTIFIED THROUGH ROUTINE SCREENING IN THE PRIMARY CARE SETTING Natasha Travis; Jennifer Spicer; Heather Freiman. Emory University, Atlanta, GA. (*Tracking ID #1938902*)

BACKGROUND: In 2006, the Centers for Disease Control and Prevention (CDC) recommended routine one-time HIV screening for everyone aged 13 to 64 years in healthcare settings. However, these recommendations have not been widely adopted and missed opportunities for HIV diagnosis continue to exist. The objectives of this analysis were to describe the characteristics of newly diagnosed HIV-infected patients identified through a routine HIV screening program and to determine whether missed opportunities for earlier diagnosis still exist in the era of routine HIV screening.

METHODS: In July 2013, a routine HIV screening program was instituted in the primary care center of an inner-city hospital located in a high HIV prevalence area in the South. All newly diagnosed HIV-infected patients were identified and a retrospective chart review was performed to describe patient demographics, CD4 count at diagnosis, previous HIV tests and results, prior access of the healthcare system, and any indications for earlier HIV testing.

RESULTS: In the first 6 months of the screening program (July–December 2013), 2,814 patients were tested for HIV. There were 20 patients with reactive HIV antibody tests: 14 patients were confirmed to be HIV positive via Western Blot and 5 patients were false positive (0.18%). Eight of the fourteen HIV positive patients were newly diagnosed HIV positive (0.28% new positive diagnosis), and a chart review was

conducted for those eight patients. All newly diagnosed HIV patients were African American and six (75.0%) were female. The average age at diagnosis was 48 years (range: 33–59 years). Five patients (62.5%) were diagnosed during a routine office visit and had no HIV-related symptoms. Four patients (50.0%) had at least one previous negative HIV test (range: 2–5 tests), and the mean number of months since most recent negative HIV test was 28 months (range: 13–37 months). All patients had healthcare visits in the emergency or primary care center within the previous 19 months yet had not been screened for HIV. Two (25.0%) of the patients had no obvious risk-based indication for an HIV test observed in the medical chart. The mean CD4 count of the patients with a previous negative HIV test was 437 cells/uL (range: 332–542 cells/uL) versus 86 cells/uL (range: 64–107 cells/uL) for those with no previous HIV test.

CONCLUSIONS: All patients newly diagnosed with HIV through our primary care HIV screening program had been seen in our healthcare system within 19 months prior to diagnosis, but only half had a previous HIV test documented despite the 2006 CDC recommendation for routine screening. Half of the patients had at least one previous negative HIV test indicating that repeat HIV screening is likely needed to identify all patients with HIV; however, more studies are needed to determine the appropriate time interval for repeat testing to make it cost-effective. The average CD4 count for patients who had a previous negative HIV test was significantly higher than those with no previous HIV test indicating that repeat HIV screening is effective at detecting HIV at an earlier stage.

MISTRUST, MISPERCEPTIONS, AND MISCOMMUNICATION: A QUALITATIVE STUDY OF PREFERENCES ABOUT KIDNEY TRANSPLANTATION AMONG AFRICAN-AMERICANS Melissa W. Wachterman^{1,2}; Ellen P. McCarthy^{3,4}; Edward R. Marcantonio^{3,5}; Mary Ersek^{6,7}. ¹VA Boston Healthcare System, Jamaica Plain, MA; ²Brigham and Women's Hospital, Boston, MA; ³Beth Israel Deaconess Medical Center, Boston, MA; ⁴Harvard Medical School, Boston, MA; ⁵Beth Israel Deaconess Medical Center, Boston, MA; ⁶School of Nursing, Philadelphia, PA; ⁷Philadelphia VA Medical Center, Philadelphia, PA. (*Tracking ID #1939528*)

BACKGROUND: There are significant racial differences in the rates of kidney transplantation in the United States, with lower rates among African-Americans with end-stage renal disease (ESRD) than among Whites. Well-documented racial disparities in access to transplantation explain only some of these differences, and prior survey-based research found that African-American dialysis patients are also less likely than Whites to desire transplantation. Our primary objective was to explore African-American dialysis patients' preferences about kidney transplantation. A secondary objective was to compare patients' expectations about transplantation with their actual status on the transplant list.

METHODS: We conducted semi-structured interviews with African-American patients receiving chronic hemodialysis (HD) at one urban dialysis center. We asked patients about their preferences about transplantation, experience with the transplant evaluation process, and sense of transplant candidacy. After the interview, we reviewed the transplant list to determine which patients were listed for transplant. We analyzed the interviews using the constant comparative method of qualitative data analysis. Transcripts were coded independently by two investigators and consensus on dominant themes was achieved. Interviews were conducted until thematic saturation.

RESULTS: We interviewed 16 African-American patients (63% men, median age 52.5, median time since HD initiation 2.8 years). From our semi-structured interviews about kidney transplantation, six major themes were identified: 1) Varied patient preferences—transplant was central goal for some, while others were ambivalent or uninterested because they feared transplant rejection or did not find dialysis burdensome. 2) Mistrust of organ allocation system—including specific concerns with inequities in the quality of cadaveric kidneys. 3) Fear of risking a living donor's health. 4) Barriers to transplantation—most commonly the extensive pre-transplant evaluation, which some felt exists as an intentional barrier to transplantation. 5) "God will heal my kidneys"—led to denial of need for transplantation. 6) Fear that they might assume the donor's personality. Only two of the 16 participants were active on the transplant list, and, in five cases, the patient's understanding of his/her listing status was discordant with actual status on the transplant list.

CONCLUSIONS: African-American HD patients have nuanced beliefs and preferences about kidney transplantation. Religious faith, concerns about risking a living donor's health, and the feeling that dialysis is not burdensome play a role in preferences against transplantation. The misperception that a transplant recipient can

take on the personality of the donor is a particularly unexpected finding. However, the strongest underlying theme is mistrust of the allocation process. Thus, addressing both racial disparities in access and lack of trust in the system are critical to affecting preferences. The discordance between patients' perceptions of status on the transplant list and actual status also suggests important gaps in communication between African-American HD patients and their nephrologists. Additional research should be focused on validating these findings in a larger, geographically-diverse sample and examining factors that influence the development and maintenance of these beliefs and preferences.

MONEY NOT WELL SPENT: ALCOHOL-RELATED HOSPITALIZATIONS IN HOUSED AND HOMELESS PATIENTS AT A PUBLIC HOSPITAL Timothy Poore^{1,2}; Rachel Heidt²; Jeffrey A. Tice¹; William Huen². ¹University of California at San Francisco, San Francisco, CA; ²San Francisco General Hospital, San Francisco, CA. (*Tracking ID #1934291*)

BACKGROUND: Alcohol is a well-known cause of morbidity and mortality worldwide. In the United States, there are approximately 80,000 alcohol-related deaths and \$223.5 billion in healthcare costs annually. This burden disproportionately affects the homeless, with alcoholism affecting up to 73 % of homeless adults. This study aims to better characterize alcohol-related hospitalizations at San Francisco General Hospital (SFGH), comparing homeless and housed patients on service use, hospitalization costs, and frequency of specific alcohol-related diagnoses.

METHODS: This descriptive study analyzed hospitalization data from SFGH between January 1, 2009 and December 31, 2012. We extracted demographic and service use data from the University Health Consortium Database and the SFGH Electronic Medical Record. We included all patients discharged with an alcohol-related primary diagnosis using ICD-9 codes.

RESULTS: During the study period, there were a total of 1345 hospitalizations of 901 patients (560 housed, 325 homeless, and 16 unknown) with primary alcohol-related diagnoses. Of those patients, 56 % were white, 23 % Hispanic, and 11 % black. Males made up 86 % of the population, and the average age was 48 years (range 14 to 84). The most common diagnosis was alcohol withdrawal (67 %), followed by alcoholic liver cirrhosis and acute alcoholic hepatitis. Ten percent of the patients accounted for 40 % of the costs. Average cost per patient was higher in the homeless than the housed (\$20,068 versus \$16,018, $p=0.0015$), with homeless patients having more admissions during the study period (1.72 versus 1.37 admissions, $p=0.0002$). Days in the ICU, length of stay, and cost per visit did not differ significantly between the two groups ($p=.023$, 0.13, and 0.49 respectively).

CONCLUSIONS: Among patients discharged from SFGH with a primary alcohol-related diagnosis, alcohol withdrawal was the most common diagnosis, and homeless patients cost significantly more than housed patients. Interventions focused on reducing alcohol withdrawal admissions in the homeless could significantly reduce alcohol-related costs at SFGH.

MONITORING DKA & HHS WITH URINE DIPSTICK: A STICKY SITUATION Alan Hathcock¹; Suneeta Ganji²; Ishani Pathmanathan¹; Helene Hedian³; Anjali Niyogi¹. ¹Tulane Medical Center, New Orleans, LA; ²George Washington University, Washington, DC; ³University of Maryland, Baltimore, MD. (*Tracking ID #1897136*)

BACKGROUND: Diabetic ketoacidosis (DKA) and hyperosmolar hyperglycemic state (HHS) are major causes of morbidity and mortality worldwide. Standard treatment protocols require serum blood glucose monitoring that is relatively expensive and largely unavailable in resource-limited settings. Thus, urine glucose is at times substituted in these situations to monitor and treat patients with DKA and HHS. There has yet to be a study looking at the use of urine glucose and its association to serum glucose in the setting of DKA/HHS.

METHODS: We designed a prospective observational study of patients with DKA or HHS presenting to a single academic center emergency department. After consent and foley placement, serum electrolytes, urine glucose and ketones were obtained at 4-hour intervals until blood glucose was less than or equal to 250 mg/dL or time elapsed greater than 8 hours.

RESULTS: Thirteen patients were enrolled over 1 year, 8 with DKA and 5 with HHS. A total of 40 urine samples were collected. Urine glucose greater than 250 mg/dL was associated with serum glucose greater than 250 mg/dL in 10 of 13 patients

(77 %) and in 27 of 30 total samples (90 %). Stratifying for patients with HHS, this relationship was associated in 100 % of samples. Three patients with DKA had urine glucose greater than 250 mg/dL but serum glucose less than 250 mg/dL, representing 10 % of the total samples of urine glucose greater than 250 mg/dL (3 of 30). Urine glucose greater than or equal to 500 mg/dL predicted serum glucose greater than 250 mg/dL in 11 of 13 patients (85 %) and 27 of 29 total samples (93 %). Urine glucose greater than 1000 mg/dL was associated with serum glucose greater than 250 mg/dL in all 13 patients (100 %) and 25 of 26 samples (96 %). Urine glucose less than or equal to 100 mg/dL was associated with serum glucose less than 250 mg/dL in all patients ($n=8$). Of note, serum glucose greater than 250 mg/dL was associated with urine glucose greater than or equal to 250 mg/dL in all patients and samples (100 %). High urine glucose (>250 mg/dL) variably predicted high serum glucose (>250 mg/dL) but was accurate approximately 90 % of the time in patients with DKA and 100 % of the time in patients with HHS. Moreover, very high (>1000 mg/dL) and very low (<100 mg/dL) urine glucose were more consistently associated with high and low serum values, respectively.

CONCLUSIONS: Serum and urine glucose appear positively associated at high levels of serum glucose but without a clear pattern. If this trend is corroborated by future studies, urine glucose greater than 250 mg/dL in DKA/HHS likely predicts serum glucose over 250 mg/dL, thus indicating further insulin and fluid administration. This appears especially applicable for patients with HHS. Likewise, urine glucose less than 100 mg/dL may signal an endpoint for aggressive insulin administration. In non resource-limited settings, serum blood glucose measurements should still be considered the standard of care for treatment of DKA/HHS.

MULTIPLE TOBACCO PRODUCT USE AMONG YOUNG ADULT BAR PATRONS Sara Kalkhoran¹; Pamela M. Ling^{1,2}. ¹University of California, San Francisco, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA. (*Tracking ID #1937807*)

BACKGROUND: Use of non-cigarette tobacco products (e.g., hookah, cigarillos, smokeless tobacco, snus) is common and e-cigarette use is increasing among young adults. We aimed to identify what additional tobacco products young adult bar patrons use with cigarettes, and to describe multiple product users.

METHODS: We collected 4,067 cross-sectional surveys from young adults aged 18–26 in bars in Albuquerque, New Mexico using randomized time-location sampling between 2009 and 2013 as part of an evaluation of an intervention to reduce cigarette use among young adults ($N=1066$ in 2009–2010, 720 in 2010–2011, 1136 in 2011–2012, and 1145 in 2012–2013). Participants reported past 30-day use of cigarettes, snus, dip, cigarillos, hookah, and electronic cigarettes (not all products were reported in each year of the survey), demographics, and tobacco-related attitudes. Chi-squared tests were used to determine changes in product consumption during the 4 years, and logistic regression was used to determine predictors of poly-use (i.e. use of cigarettes and at least one other tobacco product in the past 30 days) in the pooled sample.

RESULTS: The percentage of study participants reporting cigarette smoking decreased from 47.5 % in 2009 to 37.4 % in 2013 ($p=<0.001$). The overall rates of poly-use were 56.5 % for non-daily (smoked on 1–24 of the past 30 days, $N=945$) and 56.2 % for daily smokers (smoked on 25–30 of the past 30 days, $N=527$), which were not significantly different. Among all poly-users, use of e-cigarettes increased from 42.1 % in 2011–2012 to 71 % in 2012–2013, while use of other tobacco products decreased during the time of study. Poly-users most frequently reported using e-cigarettes and hookah (65.8 %), followed by cigarillos (35.7 %), dip (31.6 %), and snus (19.7 %) in 2013. Figure 1 shows the percentage of product use among poly-users who are non-daily cigarette smokers and Figure 2 shows the percentage of product use among poly-users who are daily smokers. The odds of being a poly-user (versus a cigarette-only user) were higher in those who were younger (OR=3.2, 95%CI [2.1–4.7]), less educated (1.9, [1.4–2.6]), and male (2.5, [2.0–3.1]). Those who reported at least one episode of binge drinking in the preceding 30 days also had greater odds of being a poly-user (1.9, [1.5–2.4]).

CONCLUSIONS: Poly-tobacco use is frequent among young adult bar patrons in Albuquerque, New Mexico, where the majority of cigarette smokers reported currently using at least one other tobacco product. While we observed a decrease in cigarette smoking (which may have been due to the anti-smoking intervention taking place during the study), the use of e-cigarettes increased significantly, exceeding use of hookah, snus, dip, and cigarillos among poly-users in 2013. Clinicians seeing young adult patients should assess use of other tobacco products in addition to cigarettes, particularly e-cigarettes.

NATURAL EXPERIMENT TO EVALUATE PATIENT CENTERED MEDICAL HOME INTERVENTION ON DIABETES OUTCOMES Edwin Young¹; Naabia Casely-Hayford¹; Nancy Sohler²; Brenda Matti - Orozco¹; Jeanine Albu¹. ¹Mount Sinai Health System, New York, NY; ²City University of New York, New York, NY. (Tracking ID #1941683)

BACKGROUND: The patient-centered medical home (PCMH) emphasizes care coordination and communication. Among the tools for care coordination, registries of high risk patients enable PCMH practices to efficiently use rare resources, such as certified diabetes educators (CDE) and endocrinologists. However, it is often difficult to identify those interventions that produce meaningful outcomes. In this study, we used a natural experiment, comparing two clinics in which PCMH was implemented at different times, to evaluate the effect of the PCMH on diabetes outcomes. Our hypothesis was that the mean A1C would be reduced in the PCMH clinic.

METHODS: We compared two clinics in New York City. In Clinic 1, the treatment group, a PCMH approach was implemented in July 2011 with 580 diabetics. The PCMH used registries of patients with A1C greater than 9, and monthly meetings with providers, staff and CDEs to develop individualized patient improvement plans. In Clinic 2, standard care was provided to 303 diabetics. The following data was obtained from the Electronic Health Record (eClinicalworks) for each patient: Clinic Facility, Date of Birth, Gender, Language, Race, Ethnicity, Encounter Date, A1C Value, BMI, and Assessments at each visit (from which was calculated a Carlson Index of comorbid diseases). Results were analyzed using R statistical software.

Missing data was imputed to the mean or the mode for each variable, for continuous and categorical variables respectively. We included a flag for missingness as a variable. Propensity for being in the treatment group was calculated for each patient using age, gender, language, race, ethnicity, BMI, Carlson Index and missingness. The mean A1C values were weighted using the Inverse Propensity for Treatment. The weighted mean A1C for each patient in the first 6 months was compared to the weighted mean A1C in the second 6 months of 2011. To illustrate the effect of the intervention in the treatment clinic, we displayed the data as a time series, interrupted at the time of the intervention, with regression lines before and after.

RESULTS: The overall change in weighted mean A1C for clinic 1 was -0.2709455 ; for clinic 2, -0.4830450 , p-value = 0.2298. Alternative hypothesis: true difference in means is not equal to 0; 95 % confidence interval: -0.1346132 0.5588123 . For only those patients whose A1C in the first 6 months was above 9, the change in weighted mean A1C for clinic 1 was -1.6139261 ; for clinic 2, -0.4496943 , p-value = 0.01523. Alternative hypothesis: true difference in means is not equal to 0; 95 % confidence interval: -2.0981380 -0.2303256 .

CONCLUSIONS: For the general diabetic patients in our study, being affiliated with a PCMH did not significantly affect the mean A1C value. But, for those patients with a mean A1C above 9, our model of the PCMH produced significant benefits. This is consistent with the intervention, which was targeted at patients with A1C above 9. Natural experiments analyzed using Inverse Probability of Treatment Weighted (IPTW) outcomes and interrupted time series can identify those interventions that produce significant improvements in selected patient populations.

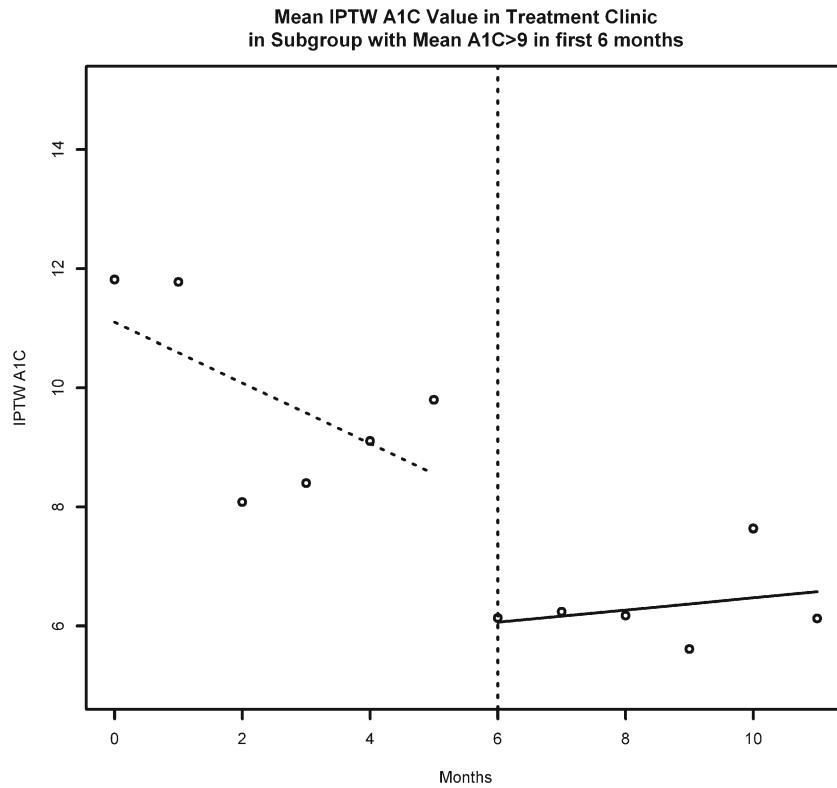

Fig. 1. Interrupted time series with regression lines before and after the intervention to illustrate treatment effect

NEGOTIATING EMERGENCY DEPARTMENT ADMISSION HANDOFFS: EXPERIENCES, BELIEFS, AND PERCEPTIONS OF ADMITTING AND EMERGENCY PHYSICIANS Christopher J. Smith; Denise H. Britigan; Nathan Anderson; Elizabeth Lyden; Tedd Welniak; Michael C. Wadman. University of Nebraska Medical Center, Omaha, NE. (Tracking ID #1936119)

BACKGROUND: Transfer of care between healthcare providers is a vulnerable time for patient safety, and ED admission handoffs are subject to unique structural and

contextual challenges. The ED admission process involves changes in provider, department, and physical location. It also occurs early in a patient's evaluation when the clinical trajectory is uncertain. Despite these challenges, there is relatively little research on ED admission handoffs. To better understand the barriers to effective handoff communication, we surveyed admitting and emergency physicians about their experiences, beliefs, and perceptions.

METHODS: A cross-sectional survey was conducted at a 627-bed tertiary-care teaching hospital. Questions were created to examine five domains: clinical content,

interpersonal perceptions, expectations, organizational factors, and patient safety. Surveys were distributed to residents, fellows, and faculty physicians from emergency medicine (EM) and six medical admitting services, which account for two-thirds of ED admissions. Data was analyzed using SPSS software. Fisher's Exact Test was used to compare dichotomized responses between EM and admitting physicians. Non-dichotomized distribution was analyzed using the Mann-Whitney Test. Examples of adverse outcomes related to handoff were categorized independently by two physicians with disagreements settled by consensus. Based on preliminary survey results, a supplemental study was designed to determine the frequency in which 8 pieces of handoff information were communicated: working diagnosis, relevant past medical history, relevant physical exam findings, results of relevant diagnostic studies, therapeutic interventions initiated, trend in the patient's clinical condition, patient's clinical condition at the time of handoff, and pending diagnostic studies. Prospective data was collected by a hospitalist immediately following oral handoff and was documented as communicated without prompting, communicated with prompting, or not communicated.

RESULTS: A total of 117 admitting (67%) and 32 EM (86%) physicians completed the survey. There was significant disagreement between EM and admitting physicians across multiple domains. Admitting physicians reported communication of clinical information occurred less frequently than EM physicians (p -value <0.05 for all eight content areas). Nearly all EM physicians felt they had to defend their decisions and face-to-face communication was rare. Sixty-three percent of respondents could not identify who was responsible for patients "boarding" in the ED. Competing clinical duties frequently distracted physicians during handoff, but environmental factors more commonly distracted EM physicians (p =0.007). Sequential handoffs occurred regularly and were felt to have negative impact on patient care. Adverse outcomes related to handoff communication were reported by 30 % of respondents, most of whom reported multiple events. Thirty examples of adverse events were reported. Final categorization is under way, but errors in communication, assignment of responsibility, and boarding were common. Prospective data from 89 admission handoffs were collected. The frequency in which specific clinical information was communicated varied from 35 to 95 % and prompting from the admitting physician was common (73 % of admissions). The content areas least frequently communicated were treatments initiated in the ED (71.9 %), trend in the patient's clinical condition (57.3 %), and pending studies (34.8 %).

CONCLUSIONS: These results highlight several barriers to the safe transfer of patients from the ED. Admitting and EM physicians had vastly different perceptions about communication of clinical information, although most information was communicated regularly. Inter-disciplinary biases, differing expectations, and egocentric anchoring likely play a role in this discrepancy. The frequency of prompting during handoff suggests that dialogue between EM and admitting physicians was common, but lack of standardized communication may have also contributed. In addition to inconsistent transfer of information, handoffs were further compromised by sequential handoffs, lack of face-to-face communication, distractions, and lack of clearly delineated responsibilities. These results demonstrate the complex interplay of factors that impact admission handoffs. Successful improvement efforts will need to address the dynamic quality of content, institutional culture and policies, environment, and organizational factors. Collaborative interventions may include interdisciplinary team-building, expanded handoff training, implementation of bedside handoffs, and better leveraging of the electronic health record.

NEW YORK CITY GREEN CARTS: IS THE PROGRAM ALLEVIATING FOOD DESERTS? Kathleen Y. Li^{1,2}; Ashley Fox²; Ellen K. Cromley^{3,4}; Carol Horowitz². ¹University of California, San Francisco School of Medicine, San Francisco, CA; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³University of Connecticut School of Medicine, Farmington, CT; ⁴Lund University, Lund, Sweden. (Tracking ID #1936558)

BACKGROUND: As the proportion of overweight and obesity nears 70 % in the United States, local public health departments are using their authority to implement programs to tackle this growing epidemic. Limited access to fresh fruits and vegetables in low-income neighborhoods is believed to contribute to high rates of obesity. To address the high rates of obesity and related illnesses in its low-income neighborhoods, in 2008, New York City established a fruit and vegetable street vendor program (NYC Green Carts) to promote healthier eating in neighborhoods with the lowest reported rates of fruit and vegetable consumption. Carts are free to move anywhere within designated neighborhoods, which can be large and often border wealthier neighborhoods. We aimed to study whether carts locate in areas that enable them to reach the low-income "food desert" populations they were designed to serve.

METHODS: We obtained a list of Green Cart locations from the New York City Department of Health and information on census tract level demographic and food environment data from the census bureau and Esri Business Analyst Desktop. We identified "healthy" food stores, namely supermarkets, independent grocers, and fruit and vegetable specialty stores according to North American Industry Classification

System codes as well as bodegas with evidence of selling fresh produce on Google Maps Street View. We then defined a food desert as a lack of healthy food stores within a ¼ mile. Using ArcGIS software, we mapped the existing Green Carts and generated a list of potential Green Cart locations. Within designated Green Cart areas, the intersection closest to the geographic center of each census tract without a Green Cart was coded as a candidate site. We then analyzed census tract characteristics for actual and candidate Green Carts to determine how they differed with regards to population, income, percent below the poverty level, distance to subway stops, the number of large employers, and the number of healthy food stores at both a ¼-mile and ½-mile distance from each location.

RESULTS: Our team identified 265 Green Carts and 644 candidate locations without Carts. As compared with potential Green Carts sites (see table), Green Carts were significantly more likely to be within a quarter of a mile of supermarkets, grocery and fruit & vegetable stores. Over 1/3 of candidate intersections with no Green Carts were situated in food deserts compared to fewer than 1/10 of Green Carts. Green Carts were positioned in tracts with significantly larger population sizes, tended to be closer to a subway stop, and were more likely to be within a ¼ mile of large employers, though Green Cart tracts had a lower median family income compared to tracts with candidate sites. Some (22) Green Carts were located outside the officially designated Green Cart areas, and these census tracts had significantly higher income and higher access to fruits and vegetables than those within Green Cart boundaries.

CONCLUSIONS: Compared with potential Green Cart locations, census tracts with Carts tended to be located in areas with large numbers of potential customers, namely population centers and areas with more pedestrian traffic (close to subway stops and large businesses), perhaps to increase market share and profitability. However, Green Carts were rarely situated in food deserts. This suggests that many already underserved neighborhoods are still not reached by this initiative. A market-driven imperative to locate near larger numbers of potential customers may be in tension with the objective of the Green Carts program to increase access to fresh fruits and vegetables in regions with lower access to supermarkets and fresh produce. However, we also identified a number of candidate locations where foot traffic is likely to be high but where Green Carts were not located. Since people usually shop close to where they live, the Green Carts program should consider introducing added incentives for Green Cart vendors to locate in high need census tracts to ensure adequate coverage of actual food deserts.

Table. Average Characteristics of Green Cart vs Candidate Sites

Variable	Green Cart Site	Candidate Site	p value
Tract population	5,004	3,706	<0.00001
Tract median income	\$37,213	\$42,740	0.000284
Percent of tract below poverty level	30.1 %	25.6 %	<0.00001
Distance to nearest subway stop (ft)	793	3,079	<0.00001
# large employers within ¼ mi	0.457	0.085	<0.00001
# supermarkets within ¼ mi	1.6	0.81	<0.00001
# other stores carrying fruits and vegetables within ¼ mi	2.09	0.84	<0.00001
# large employers within ½ mi	1.185	0.402	<0.00001
# supermarkets within ½ mi	4.72	2.86	<0.00001
# other stores carrying fruits and vegetables within ½ mi	5.4	3.1	<0.00001

NONINVASIVE MECHANICAL VENTILATION USE IN THE ELDERLY: APPROPRIATENESS OF THERAPY, ADEQUACY OF ASSESSMENT, AND EVENTUAL OUTCOMES Tarak Rambhatla; Adam Bierzynski. Lenox Hill Hospital, New York, NY. (Tracking ID #1934152)

BACKGROUND: NIPPV has long been shown to be an effective therapy in selected patients with acute respiratory failure as an alternative to endotracheal intubation. Many studies have been done to assess predictors of failure for this therapy, but our search of the literature did not show any studies that assessed the efficacy and application of NIPPV therapy specifically in the elderly. As this population is the most likely to present with acute respiratory failure, it is important to know how effective NIPPV therapy is in this group and whether it is being used appropriately. Our objective is to analyze the appropriateness of the application of non-invasive positive pressure ventilation (NIPPV) at our institution, by comparing patient selection for NIPPV and the difference in outcomes between the elderly and younger patient populations.

METHODS: Retrospective study of all NIPPV ordered for medical patients over a two-month period at a single center university-affiliated teaching hospital. One hundred twenty-seven patients ordered for NIPPV identified by respiratory therapy

records and a retrospective chart review with the use of MAR to collect data on each patient prior to and during the course NIPPV therapy.

RESULTS: Group 1 was defined as elderly with ages 70 years or older and group 0 below 70. Chronic obstructive pulmonary disease and congestive heart failure accounted for less than 50 % of admission diagnoses in either group. There was no significant difference in echocardiographic evaluation (63 % vs. 57.4 %, $p=0.586$), or cardiac function (19.7 % vs. 11.5 %, $p=0.429$). 59.1 % of the elderly group had an arterial blood gas (abg) performed prior to ordering NIPPV (vs. 32.8 %, $p=0.003$). There was no significant difference in acid-base status amongst the groups nor was there a significant difference in patients that had a repeat abg while being treated with NIPPV (30.3 % vs. 23.0 %, $p=0.424$). Group 1 had NIPPV therapy ordered for a longer duration of time (5.82 days vs. 4.95 days, $p=0.045$) and total length of use was longer (5.38 days vs. 4.61 days, $p=0.06$). Group 1 was more likely to have a pulmonary infiltrate (66.7 % vs. 45.9 %, $p=0.021$) and more likely to be treated with antibiotics (72.7 % vs. 47.5 %, $p=0.006$). The elderly population had 13 patients that required escalation of care while 4 patients in the younger population required an escalation of care (19.7 % vs. 6.6 %, $p=0.026$).

CONCLUSIONS: We found NIPPV was consistently being ordered for conditions not proven to benefit from NIPPV and there was an inadequate assessment of oxygenation/ventilation status prior to and during the course of NIPPV therapy for all ages. We also found the elderly population, despite not showing a significant difference in cardiac function or oxygenation/ventilation status were being treated with NIPPV for longer periods of time, had more lung infiltrates, use of antibiotics, and had more patients requiring escalation of care. Further investigation into NIPPV use in elderly patients may help identify which factors predict an adverse outcome in this patient population.

	Group 1 (70 years or older)	Group 2 (less than 70 years)
Duration NIPPV ordered (days)	5.82	4.95 ($p=0.045$)
Length of use of NIPPV (days)	5.38	4.61 ($P=0.06$)
Patients with pulmonary infiltrate (%)	66.7	45.9 ($p=0.021$)
Patients being treated with antibiotics (%)	72.7	47.5 ($p=0.006$)
Patients requiring escalation of care (%)	13	4 ($p=0.026$)

NOT ALL INTERNS ARE CREATED EQUAL: UNDERSTANDING MEDICAL SCHOOL EXPERIENCES PRIOR TO STARTING INTERNAL MEDICINE RESIDENCY TRAINING Luke Cunningham; Chirayu Shah; Steffanie Campbell; Anoop Agrawal; Kaushal Patel; Nainesh Shah; Prathit Kulkarni; Richard J. Hamill. Baylor College of Medicine, Houston, TX. (Tracking ID #1941642)

BACKGROUND: As new residents start their Internal Medicine training in July, many studies have raised concerns about patient safety associated with inexperienced residents, also termed the "July effect." The clinical experiences and curriculum to prepare graduating medical students for internship can vary between medical schools. The purpose of this study was to characterize medical school training in skills required for incoming Internal Medicine interns to provide safe patient care.

METHODS: Prior to Internal Medicine orientation at Baylor College of Medicine, 44 categorical interns, 16 preliminary interns, and 8 medicine-pediatric interns (total of 68 interns) were sent a survey to complete about their training and skills during medical school.

RESULTS: The response rate for the survey was 100 % (68/68). Of the 68 interns, only 53 % had participated in a fourth year medical school course geared towards preparing for intern year. Of the 29 medical schools represented within the intern class, 12 (41 %) offered an internship preparation course. There were 26 interns (38.2 %) that never worked an overnight shift or taken overnight call during their Internal Medicine rotations. Only 35 % of interns reported any formal training about patient handoffs. Forty-four interns (64.7 %) reported no experience in providing cross coverage for patients not admitted to them. In terms of procedural experience, 15 % had performed a thoracentesis, 31 % had placed a central line, 47 % had performed a paracentesis, 48 % had done an arterial blood gas, 81 % had placed peripheral IV access, and 88 % had drawn blood. In addition, 66 % of interns had participated in a live code blue situation. When asked about intern orientation, 98.5 % expected to learn about their clinical responsibilities and 97.1 % expected training in skills needed for intern year.

CONCLUSIONS: There is significant variability in the experience and skills of interns starting their residency training in Internal Medicine. Although internship preparation courses during the end of medical school training may play a role in improving intern skills, these courses are not available across all medical schools. The results of this study suggest that incoming interns may not be adequately prepared for starting residency training. Incoming interns expect some skills training during their orientation. With the adoption of Internal Medicine residency milestones, residency

programs need to invest in a training curriculum and milestone-based evaluations for incoming interns prior to starting their clinical duties.

OBESITY IN PRIMARY CARE: KNOWLEDGE OF HEALTH RISKS AND DESIRE TO LOSE WEIGHT Katherine H. Saunders; Erica Phillips; Keith Roach. New York-Presbyterian Hospital, New York, NY. (Tracking ID #1928350)

BACKGROUND: Research has shown that many patients do not accurately classify their weight status category. This misperception is a strong predictor of weight loss attitudes and behavior. In addition, most obese and overweight patients have been diagnosed with at least one obesity-associated health condition; however, there has been limited data on patients' knowledge of which medical conditions are linked to obesity. This study evaluates patients' perception of their weight category, their awareness of the impact of obesity on a variety of health conditions, and their desire and action to lose weight.

METHODS: Through an anonymous questionnaire, adult patients were surveyed using convenience sampling at a hospital-based primary care practice staffed by attendings and residents. Surveys were distributed in the waiting room on different days of the week, at different times of day. Participation was voluntary and no incentive was provided.

RESULTS: Of 904 patients approached, 652 (72 %; 65.6 % female, 34.3 % male, mean age 53.0 years, range 18–91 years) completed the questionnaire. The mean self-reported BMI (calculated from self-reported height and weight) was 28.4 (range 12.8–66.1, 8.0 % obese, 42.0 % overweight, 37.6 % normal weight). Only 43.3 % of self-reported obese or overweight participants consider their weight to be a health problem and only 30.9 % recall that a physician or health professional told them in the past year that they were obese or overweight. The most commonly diagnosed health condition was hypertension (41.7 % of participants) followed by dyslipidemia (39.8 %), asthma (22.0 %), osteoarthritis (21.6 %) and type 2 diabetes (20.6 %). Approximately 85 % of participants cited hypertension, dyslipidemia and type 2 diabetes as obesity-related health conditions, whereas only 69.7 % and 56.0 % cited osteoarthritis and asthma respectively as conditions related to obesity. Interestingly, 68.2 % of all participants would like to weigh less and 64.7 % have tried to lose weight or taken action to prevent gaining weight during the past year.

CONCLUSIONS: Preliminary findings indicate that 85 % of participants are able to associate common health conditions to obesity yet only 43 % of obese and overweight participants consider their weight to be a health problem for themselves and only 30 % recall a healthcare professional addressing their obesity/overweight. Furthermore, almost 70 % of participants would like to weigh less despite only 50 % of patients considering themselves obese or overweight. Based on these initial data, there appear to be motivating factors other than health driving patients' desire to lose weight. Future research should focus on identifying these other factors motivating weight loss as well as training healthcare professionals to counsel patients accordingly. Finally, the healthcare community should place more of an emphasis on the association between health risks and weight status on an individual level.

OBESITY, DISORDERED EATING BEHAVIORS, AND DIFFICULTY MAKING DIETARY CHANGES AMONG PRIMARY CARE PATIENTS WITH MODERATE TO SEVERE OBESITY Sara A. Chacko^{1,2}; Sarah N. Chiodi^{1,2}; Christina C. Wee^{1,2}. ¹Beth Israel Deaconess Medical Center, Boston, MA; ²Harvard Medical School, Boston, MA. (Tracking ID #1935987)

BACKGROUND: Disordered eating behaviors are prevalent among obese patients seeking weight loss treatment and may impact their ability to make clinically recommended dietary changes. However, few studies have characterized these behaviors among obese patients in primary care or whether these behaviors adversely impact patients' ability to lose weight. Therefore, we aimed to determine the prevalence of disordered eating behaviors in primary care patients with obesity and identify patients at risk. We also examined how eating behaviors are related to patients' reported difficulty with making dietary changes.

METHODS: We interviewed by telephone 337 primary care patients (58 % response rate) with BMI>35 kg/m² at 4 diverse primary care clinics in Greater-Boston. We measured cognitive restraint, uncontrolled eating, and emotional eating using the Three-Factor Eating Questionnaire R-18 (TFEQ-R18) (Scores 0–100). We characterized scores >50 as "high" indicating that respondents answered 'definitely true' or 'mostly true' more than 50 % of the time in response to a series of maladaptive eating behaviors. We measured dietary self-efficacy using four questions assessing difficulty in making dietary changes (Scores 0–10). Respondents were asked to rate on a scale of 0–10, where 0 is not at all difficult and 10 is extremely difficult, how difficult it is to limit the portion size, total amount of calories, fat in diet, and the amount of carbohydrates in food. We categorized scores ≥7 as "high difficulty" in making dietary changes. We developed multivariable-adjusted models to examine the relationship between disordered eating and difficulty making dietary changes. Models were adjusted for age, race, sex, education, study site, and BMI.

RESULTS: 49.2 % of patients reported scores >50 for emotional eating (mean = 48.0); 27.9 % reported scores >50 for uncontrolled eating (mean = 37.6). After adjustment, women reported significantly higher scores on emotional eating [$\beta=18.55\pm3.91$ ($p<0.0001$)] than men. Compared to Caucasians, African Americans reported lower scores on emotional eating [$\beta=-20.02\pm4.84$ ($p<0.0001$) and uncontrolled eating [$\beta=-18.94\pm3.49$ ($p<0.001$)]. As expected, higher BMI was associated with higher scores on uncontrolled eating. Patients who reported emotional eating were more likely to report high difficulty (>7 of 10 on difficulty scale) with reducing portion sizes [OR=2.74 (2.00, 3.80)], calories [OR=2.12 (1.55, 2.89)], fats [OR=2.13 (1.52, 2.99)], and carbohydrates [OR=3.75 (2.58, 5.43)].

CONCLUSIONS: The prevalence of disordered eating behaviors is high among obese primary care patients and disproportionately affects women and Caucasians. These maladaptive eating behaviors may impact patients' ability to make dietary changes and limit the success of weight loss treatments. Primary care clinicians should consider screening for and intervening on disordered eating in their patients.

OBSERVATION UNITS AS SUBSTITUTES FOR HOSPITALIZATION OR HOME DISCHARGE Saul Blecker, Keith Goldfeld; Joseph Ladapo; Stuart Katz. NYU School of Medicine, New York, NY. (*Tracking ID #1936943*)

BACKGROUND: Observation units have been associated with quality care at relatively low cost. However, studies of the economic impact of observation units have compared their cost to hospitalization without considering an alternative disposition following an emergency department (ED) visit, i.e., discharge to home. There is evidence from other clinical interventions that increased availability of services can increase overall utilization even in the absence of improvements in quality. This same supply-induced demand may shift patients who would otherwise be discharged home to be admitted to observation units following an ED visit. To determine the potential for alternative post-ED dispositions for these patients, we studied ED visits for chest pain that resulted in discharge to observation units.

METHODS: We identified all ED visits for chest pain in 2009–2010 from the National Hospital Ambulatory Medical Care Survey, a nationally representative sample of ED visits in the United States. First we developed a predictive model for likelihood of hospitalization versus discharge to home for visits to hospitals without an observation unit. Variables considered as predictors for the model included demographic characteristics, comorbid conditions, vital signs, and ED characteristics. The model was validated among patients with chest pain who were cared for at hospitals with observation services and subsequently either hospitalized or discharged. Probability of hospitalization was categorized as: hospitalization likely ($p(\text{hospitalization})>0.75$), discharge likely ($p(\text{hospitalization})<0.25$), and intermediate ($0.25< p(\text{hospitalization})<0.75$) to reflect clinical uncertainty. These categories were then applied to patients who were admitted to an observation unit to predict likely disposition if observation services had not been available.

RESULTS: This study included 2,071 ED visits for chest pain, representing 8,257,881 ED visits in the United States. Of these visits, 31.7 % resulted in hospitalization while 13.4 % led to an observation unit admission; 51.9 % of visits were at facilities with available observation services. In the final prediction model, a number of variables were significantly associated with subsequent hospitalization, including age, use of oxygen, history of heart failure, and recorded urgency at triage. The model had fair discrimination in both the training (c-statistic = 0.77) and validation (c-statistic 0.73) datasets. The positive predictive value for hospitalization was 80 % while the predictive value for discharge was 85 % (71 % and 84 %, respectively, for the validation dataset). Among visits subsequently admitted to the observation unit, the model predicted 7 % as hospitalization likely, 32 % as discharge likely, and 61 % as intermediate.

CONCLUSIONS: One third ED visits for chest pain that resulted in an observation unit admission were for patients who would have been discharged to home had the observation unit not been available. Economic evaluations of observation units must consider the potential cost of increased utilization related to patients who otherwise may have been discharged. Policies such as Medicare's recently adopted "Two Midnight Rule", which was implemented to curb payment for short stay hospitalizations and will likely result in an increased number of hospital observation unit beds, may have the unintended consequence of increasing the total number of patients treated in the hospital following an ED visit.

OLDER ADULTS' ATTITUDES ABOUT RECEIVING TEXT MESSAGES RELATED TO COLORECTAL CANCER SCREENING Nancy M. Denizard-Thompson¹; Kathryn E. Weaver²; Shellie D. Ellis³; Donna Kronner²; David P. Miller¹. ¹Wake Forest School of Medicine, Winston-Salem, NC; ²Wake Forest School of Medicine, Winston-Salem, NC; ³University of North Carolina, Chapel Hill, NC. (*Tracking ID #1933666*)

BACKGROUND: Over 70 % of American adults now send text messages on a regular basis. This technology could be a valuable tool to support primary care patients, particularly as they prepare for cancer screening services. To determine whether older adults would value or access text messages from their physician's practice, we conducted a qualitative study examining the utility of text messages to support colorectal cancer (CRC) screening.

METHODS: We recruited English-speaking patients aged 50–74 years from 3 community-based practices affiliated with a large academic medical center. One practice served a primarily socioeconomically disadvantaged population. We queried electronic health records to identify two patient groups for mail recruitment: those with a recent colonoscopy and those with no colonoscopy in the past 10 years. We screened patients by telephone and invited eligible patients to attend one of 4 focus groups in community settings. A trained moderator led all groups, following a semi-structured interview guide. Topics included perceived barriers and facilitators to CRC screening, personal use of electronic communications, and attitudes/beliefs about the utility of receiving medical text messages. We also elicited feedback about a series of text messages regarding specific CRC screening tests. Text messages were shared with participants either via their cellphones or by color screenshots.

RESULTS: A total of 27 adults participated in 1 of the 4 focus groups. Participant age ranged from 50 to 73 years (mean = 57 years). Two-thirds of participants were female (17/27) and Black (17/27). Over 25 % had low health literacy (8/27) or were overdue for CRC screening (7/27). Participants reported the main barriers to CRC screening were distaste for the prep solution, fear of the procedure, and fear of bad results. Some stated they were not aware of any screening option other than colonoscopy. Attitudes about receiving text messages from a physician's office were mixed. Main concerns included confidentiality (fear that someone else would read their texts), intrusiveness (text messages could come at inconvenient times), depersonalization of the patient-physician relationship, and lack of confidence or dislike of texting (for those who did not text currently). Despite these concerns, participants reacted positively to many of the sample text messages. Participants particularly liked text messages that were affirming ("I'm glad you decided to do the stool blood test"), supportive ("Hang in there, I know the prep and clear diet can be challenging"), and informative ("Remember you will need to have someone take you to the test tomorrow"). Participants also favored texts that included their first name, which confirmed the message was intended for them. Participants did not like text messages which asked them to reply back with specific information such as the date of their planned colonoscopy. In general, participants felt providing a choice of communication modalities was important, such as offering texts, e-mails, or phone calls.

CONCLUSIONS: Text messages may be a feasible way to provide CRC screening reminders to older adults; however, it is important to offer other communication options such as email for non-texters. Older adults liked text messages that were positive in tone and contained key information. Health systems should address patients' concerns about text message confidentiality if they plan to use this communication modality.

ONCE-DAILY TIOTROPIUM RESPIMAT® DECREASES THE RISK OF EXACERBATIONS, INDEPENDENT OF BASELINE CHARACTERISTICS, IN PATIENTS WITH SYMPTOMATIC SEVERE ASTHMA WITHOUT EVIDENCE OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE Jonathan Corren¹; Kevin R. Murphy²; Gregory Bensch³; Ronald Dahl⁴; Pierluigi Paggiaro⁵; Michael Engel⁶; Petra C. Moroni-Zentgraf⁶; Hendrik Schmidt⁷; Huib A. Kerstjens⁸. ¹University of California, Los Angeles, CA; ²Boys Town National Research Hospital, Boys Town, NE; ³Bensch Research & Associates, Stockton, CA; ⁴Odense University Hospital, Odense, Denmark; ⁵University of Pisa, Pisa, Italy; ⁶Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim am Rhein, Germany; ⁷Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany; ⁸University Medical Center Groningen, Groningen, Netherlands. (*Tracking ID #1939993*)

BACKGROUND: All patients (pts) with asthma are at risk of exacerbations, which are potentially life-threatening, adversely affect long-term disease outcomes, and place considerable burden on pts and healthcare systems. In pts with severe symptomatic asthma despite therapy with inhaled corticosteroids (ICS) and long-acting β_2 -agonists (LABAs), addition of once-daily tiotropium Respimat® (TioR) provides bronchodilation and reduces exacerbations (Kerstjens et al. NEJM 2012;367:1198–207). Secondary analyses may determine whether this effect is limited to subgroups of pts defined by baseline characteristics.

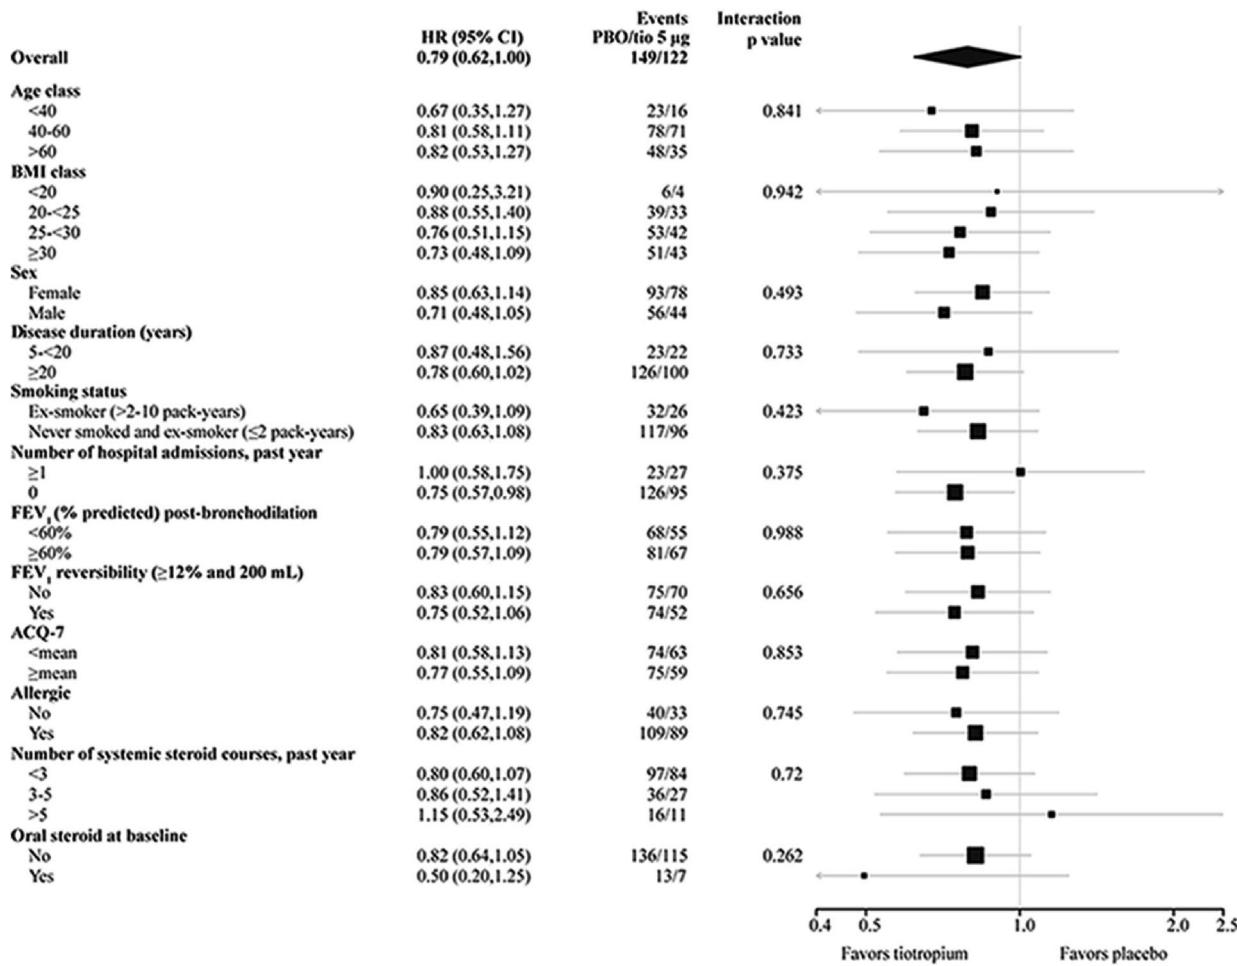

METHODS: Baseline characteristics were investigated and subgroup analyses performed using data from 2 replicate Phase III, randomized, double-blind, placebo (PBO)-controlled studies of once-daily TioR in pts with symptomatic asthma despite high-dose ICS ($\geq 800 \mu\text{g}$ budesonide equivalent) + LABA, in addition to other therapies (Kerstjens et al. NEJM 2012;367:1198–207). Eligibility criteria included: 18–75 years of age; asthma diagnosis before age 40; ≥ 5 -year history of asthma; 7-question Asthma Control Questionnaire (ACQ-7) score ≥ 1.5 ; at least 1 asthma exacerbation in the previous year; life-long non-smokers or ex-smokers (≤ 10 pack-

years) who quit smoking ≥ 1 year before study enrollment. Pts with chronic obstructive pulmonary disease (COPD) or other lung disease were excluded. Time to first severe exacerbation (defined as asthma deterioration necessitating initiation or doubling of systemic glucocorticosteroids) after 48 weeks was a co-primary endpoint. Secondary endpoints included time to first episode of asthma worsening (defined as either progressive increase in symptoms and/or a decline of $\geq 30\%$ in the best morning peak expiratory flow for ≥ 2 consecutive days). Subgroup analyses of time to first severe exacerbation were performed by baseline characteristics, including age, allergic status, smoking status, and reversibility (Figure).

RESULTS: 912 pts were randomized: 456 received TioR 5 µg and 456 received PBO Respimat® once daily for 48 weeks. Mean age: 53.0 years; 37.6 % of pts were aged ≤ 50 years. Mean age at diagnosis of asthma: 22.7 (range 0–44) years. Median asthma duration: 28.0 (range 5–72) years, with 76.5 % of pts having asthma for ≥ 20 years before enrollment. Most pts (75.9 %) were non-smokers; 24.1 % were ex-smokers with a median number of pack-years of 5.0. Mean ACQ-7 score: 2.6 (range 1–5); mean IgE: 1210 µg/L; mean pre-bronchodilation forced expiratory volume in 1 s (FEV₁): 1.5±0.5 L; mean FEV₁ bronchodilation response to

salbutamol: 15.2±15.7 % (all values baseline±SD). Time to first severe exacerbation was increased by addition of TioR versus PBO (risk reduction 21 %; hazard ratio 0.79; $p=0.03$). Time to first episode of asthma worsening increased with TioR versus PBO (risk reduction 31 %; hazard ratio 0.69; $p<0.0001$). Subgroup analyses showed that neither time to first severe exacerbation (Figure) nor time to first episode of asthma worsening was dependent on baseline characteristics (no significant interactions). The 24-hour bronchodilatory effect of TioR was demonstrated by lung function data obtained in a subset of pts. Adverse events were well balanced between TioR and PBO; no deaths occurred.

CONCLUSIONS: The increase in time to first severe exacerbation and first episode of asthma worsening in patients receiving tiotropium Respimat® was not limited to specific subgroups. Age of onset, symptom duration, lack of smoking, allergic status, and bronchodilation response provide reasonable certainty that the patients enrolled had asthma and not COPD. Features compatible with COPD were thus more likely to reflect effects of long-standing severe persistent asthma than the alternative diagnosis. Once-daily tiotropium Respimat® add-on reduces risk of exacerbations in patients with asthma who remain symptomatic and experience exacerbations despite ICS+LABA.

ACQ-7, 7-question Asthma Control Questionnaire; BMI, body mass index; CI, confidence interval; FEV₁, forced expiratory volume in 1 second; HR, hazard ratio; PBO, placebo; tio, tiotropium

ONLINE COUNSELING TO ENABLE LIFESTYLE-FOCUSED OBESITY TREATMENT IN PRIMARY CARE Kathleen M. McTigue^{1,2}; Laurey R. Simkin-Silverman²; Molly B. Conroy^{1,2}; Dana L. Tudorascu¹; Rachel Hess¹

Gary Fischer¹; Cindy L. Bryce³. ¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA; ³University of Pittsburgh, Pittsburgh, PA. (Tracking ID #1931309)

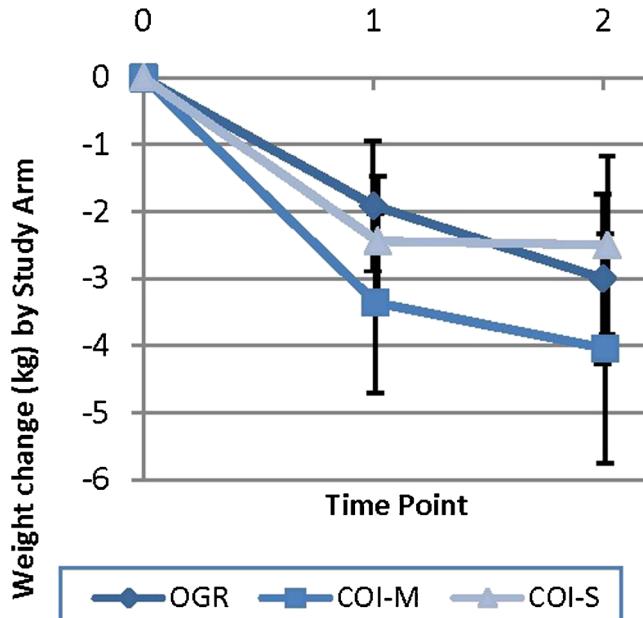

BACKGROUND: More than one third of US adults are obese. The USPSTF recommends that primary care providers (PCPs) screen for obesity and offer or refer obese patients to intensive, multicomponent behavioral interventions; however, such

treatment is rarely accessible in the primary care setting. Online counseling can provide convenient behavioral support in the setting in which lifestyle choices are made. Our prior work has shown that primary care patients find it to be a satisfactory approach for delivering intensive behavioral interventions.

METHODS: We facilitated the delivery of preventive counseling by using information technology to translate an evidence-based intensive lifestyle intervention into diverse primary care settings, and conducted a randomized controlled trial comparing the effectiveness of three online approaches for integrating behavioral lifestyle treatment with primary care medicine. Obese primary care patients were referred by their PCPs for an online weight loss intervention and randomized into 1 of 3 arms. Each participant received an in-person lifestyle counseling session plus 1 year of access to either (1) comprehensive online intervention with standard coaching (COI-S), (2) comprehensive online intervention with modulated coaching (COI-M) or (3) online goals and resources (OGR) alone. Both COI interventions included online lessons adapted from the proven Diabetes Prevention Program's lifestyle intervention, interactive workbook exercises, asynchronously delivered advice and support from a lifestyle coach, self-monitoring tools with automated feedback, and links to reputable community resources. For COI-M participants, coaches had an electronic tool that helped identify patients in need of counseling, and modulated their counseling intensity to reflect participant need (i.e., no notes were sent unless a potential concern was identified). We measured weight change and used electronic surveys to assess covariates and potential confounders at baseline, 6 months and 12 months. Fisher exact and Chi-square tests were used for our comparisons.

RESULTS: 373 obese patients were recruited from 6 primary care practices in western Pennsylvania from April to December, 2010. On average participants were age 49.4 (SD 12.6), and weighed 106.1 kg (SD 20.7). Of the sample, 76 % were female and 20 % were African American. All study arms lost weight at 6 months, with the largest estimated difference seen in the COI-M group [-3.36, 95 % confidence interval (CI): -4.70, -2.02], the smallest estimated difference seen in the OGR arm [-1.91 (CI: -2.89, -0.94)] and an intermediate estimated difference seen for the COI-S arm [-2.44 (CI: -3.39, -1.48)]. Weight loss was sustained at 12 months in each study arm, with point estimates for weight further declining in the COI-M and OGR arms over the second half of the interventions (see Figure). At each time point, there was no significant difference in weight loss between groups. Survey data indicated that the use of non-study resources for weight loss differed by study arm at 6 months of enrollment with more OGR participants using such resources than did COI-M or COI-S participants (14.4 %, 6.3 %, and 3.4 %, respectively; $p=0.015$).

CONCLUSIONS: All three interventions led to weight loss over 1 year of follow-up and weight regain was not seen in any group. While we found no statistically significant difference in the estimated differences between the three groups, the estimated weight change in each group suggests that the intensive intervention with as-needed coaching had the most clinically relevant results. The greater weight loss in the OGR (active control) group than anticipated from the literature may reflect a larger use of participants' personal resources for lifestyle management. These findings suggest that online lifestyle support can be implemented in coordination with primary care medicine.

OPPORTUNITIES FOR IMPROVING COLORECTAL CANCER SCREENING IN COMMUNITY HEALTH CENTERS - IMPACT OF ELECTRONIC HEALTH RECORD SYSTEMS: A CROSS-SECTIONAL SURVEY Allison Cole¹; Shin-Ping Tu²; Maria Fernandez³; William A. Calo³. ¹University of Washington, Seattle, WA; ²Virginia Commonwealth University, Richmond, VA; ³University of Texas, Houston, TX. (Tracking ID #1935924)

BACKGROUND: Community Health Centers (CHCs) are important sources of primary care for medically underserved populations. Adoption of electronic health records (EHRs) has increased in CHCs. EHRs represent an important tool for improving quality of preventive care including implementation of evidence based approaches for cancer control. However, to successfully implement evidence-based approaches to cancer screening, EHR data must be reliable and there must be effective systems in place for using EHR data to improve practice. The objectives of this study were to describe the proportion of CHCs reporting specific EHR functionalities important for implementation of evidence based approaches to colorectal cancer screening in CHCs and to describe the ease with which CHCs are able to complete specific colorectal cancer screening tasks using EHR systems.

METHODS: This cross-sectional study analyzed results of the Cancer Prevention Control Research Network's (CPCRN) Community Health Center survey. The CPCRN is a national network of academic, public health, and community partners who work together to reduce the burden of cancer. Institutional Review Boards at each CPCRN site as well as the Coordinating Center at the University of North Carolina at Chapel Hill and the Centers for Disease Control and Prevention approved all study procedures. We described the characteristics of responding CHCs, calculated the proportions of CHCs using EHR data to measure and improve colorectal cancer screening and estimated the perceived accuracy of EHR reported colorectal cancer screening rates.

RESULTS: The survey was completed by 50 of 75 CHCs in 7 states for a 67 % response rate. We found that 90 % of respondent CHCs have adopted EHRs. Of those with EHRs, 82 % report being able to use EHR data to measure colorectal cancer screening, but only 27 % of CHCs perceive EHR colorectal cancer screening data as very accurate. Though the majority of respondent CHCs with EHRs are able to use EHR systems to identify patients overdue for colorectal cancer screening, only 47 % report it is very easy to do these activities using EHR systems.

CONCLUSIONS: Despite widespread adoption of EHRs, the majority of CHCs do not perceive colorectal cancer screening data from EHRs as accurate. Few CHCs report that use of EHR systems to measure and improve colorectal cancer screening is either "easy" or "very easy". Poor EHR data quality and cumbersome EHR systems may be significant barriers to implementation of evidence-based approaches to colorectal cancer screening and other preventive services in CHCs. Improvement of EHR functionality in CHCs is a key to reducing disparities in colorectal cancer screening affecting the minority and low income populations served by CHCs.

OPTIMISM, RISKS, AND PERCEPTIONS OF HEALTH FOR EVALUATION OF UNDERLYING SENTIMENT (ORPHEUS) Stephanie A. Rose¹; Bharat Kumar¹; Brett Capel¹; Nicholas Jackson¹; Brittany P. Fenner¹; Sarah Schuetz¹; Dominique Zephyr²; David Rudy¹. ¹University of Kentucky, Lexington, KY; ²University of Kentucky, Lexington, KY. (Tracking ID #1940331)

BACKGROUND: Interest in the relationship between personality characteristics and health has increased substantially in recent years. One measure correlated with physical health is dispositional optimism, defined as the general expectation that good things will happen. However, the relationship between dispositional optimism and risk perception by patients remains largely unexamined. In this study, we aim to assess the correlation between objective disease risk and perception of disease risk in diabetes (DM). We hypothesize that increased levels of optimism are negatively correlated with perceptions of risk as well as with objectively measured risk.

METHODS: Patients in a university-based internal medicine clinic completed a quantitative survey assessing their level of dispositional optimism via the Revised Life Orientation Test (LOT-R), and their risk perception (RP) of developing DM. We performed chart reviews to obtain laboratory, demographic, and anthropometric data to calculate each patient's diabetes risk score based on validated risk calculators.

RESULTS: Patients ($n=28$) were 96.4 % white, 35.7 % male, mean age 54.52 years (SD 11.92), 18 % were overweight (BMI 25–29.9 kg/m²), 39 % were obese (BMI ≥ 30), and 3 patients (10 %) had a diagnosis of DM. Mean LOT-R score was 16.2 (SD 5.67) (range 0 low to 24 high). Of patients not already diagnosed with DM ($n=25$), mean RP of developing DM was 2.63 (SD 1.49) (range 1 low to 7 high). Mean objective health risk of developing DM was 3.33 (SD 1.98) (range 1 low to 6 high). There was a positive correlation between RP of developing DM and optimism ($r=$

0.077, $p=0.354$). There was a positive correlation between optimism and objective risk of developing diabetes ($r=0.465$, $p=0.007$).

CONCLUSIONS: There was no significant correlation between optimism and risk perception of developing DM. However, surprisingly, increasing optimism was significantly correlated with increasing objective risk of developing diabetes. Limitations to this analysis include small sample size. Future goals include increasing sample size and assessing the correlation between RP, optimism, and objective risk.

OPTIMIZING EVIDENCE-BASED MEDICINE SEARCHES: PATTERNS OF VISITATION TO A MEDICAL REFERENCE WEBSITE FROM GOOGLE
 Alex Montero¹; Timothy Plante¹; David J. Iberri²; Emily Coderre³. ¹Georgetown University Hospital, Washington D.C., DC; ²Stanford Hospitals and Clinics, Stanford, CA; ³Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #1939872)

BACKGROUND: Evidence-based medicine (EBM) experts cite Google as a comprehensive search engine useful for locating articles which have received significant press and media coverage. Google is not cited as a resource for finding high quality, pre-appraised evidence. Wiki Journal Club (WJC) is an independent, open-access, collaborative, medical reference website with editorial support by resident trainee physicians (the authors). The site provides standardized summaries of Internal Medicine trials in an evidence-based/journal club format similar to established sources of high quality, pre-appraised evidence. Importantly, summaries are titled by the consensus derived colloquial name of the trial. Little is known about the relationship of Google searches for individual clinical trials and traffic flow to sources of high quality, pre-appraised medical evidence websites. Google Analytics is a website analytics platform providing user visitation data. We report on a descriptive analysis of Google search visitor and query trends to WJC over a 36 week block.

METHODS: Visitor data was downloaded to Google Analytics for a 36 week period. Percentage of total weekly visitation for 4 hour and daily blocks was calculated and query specific data was analyzed for the last 92 days of the study period. Statistical analyses were performed with Google Analytics, Google Spreadsheets, and R Gui 64 bit v3.0.1. Of note, mobile application user data was excluded from this analysis.

RESULTS: From January 4, 2013 to September 12, 2013 there were 53,626 visitors to WJC who viewed 141,022 pages. Search engines contributed more than two thirds of all visitors, 95.1 % of whom were from Google. The mean weekly increase of visitation from Google was 5.7 % (2.05 to 9.32; $P=0.003$; Table 2). Most of these visitors were from the US. Most Google visitors used a computer running Windows or Macintosh operating systems with 11.5 % using mobile platforms. Google visitors were on almost 5,000 different networks, the largest owned by American commercial telecommunication firms. The top 15 medical group-associated networks contributed 5.5 % of Google visitors. In regards to query data analyses, total impressions for WJC (the amount of times a google query returned WJC in its result) during the study time frame was 146,511. Queries with the most clicks were “wiki journal club,” “affirm trial,” and “accord trial.” Finally, of 1,669 possible queries that would result in an average position <10 for WJC on a Google search, 1330 included either “wiki,” “journal,” or “club.”

CONCLUSIONS: Our analysis supports WJC’s relative success despite the lack of any formal advertising program. Additionally, we infer from our analyses that users search employing a trial’s colloquial name adjoined to “Wiki” and/or “Journal Club” rather than constructing an entire PICO format EBM search. We suspect the term “journal club” connotes some evidence-based pre-appraisal of the trial, and “wiki” connotes the collaborative nature of the content. In comparison, established sources of high quality pre-appraised evidence such as ACP Journal Club, DARE, and Bandolier do not employ any of these strategies. Not surprisingly, none of these sources appear on the first page of any of the top 20 most visited trials on WJC. As advocates and teachers of EBM, we acknowledge that WJC is not equivalent to an established source of high quality, pre-appraised evidence such as ACP Journal Club. However, we see the search factors underpinning WJC success as relevant to these established online sources of high quality EBM, and more direct collaboration and linkage with these sites is planned in WJC’s future.

Wiki Journal Club Traffic Over 36 Weeks

OPTIONS IN THE HOSPITAL: MEASURING INPATIENT INVOLVEMENT IN DECISION MAKING Zackary Berger, Mary Catherine Beach. Johns Hopkins School of Medicine, Baltimore, MD. (Tracking ID #1937967)

BACKGROUND: Shared decision-making (SDM) has become a goal of many patients and providers in contemporary health care, for humanistic reasons and in order to increase patient satisfaction. However, the implementation of SDM is still inconsistent and of unclear effectiveness. Little is known about SDM in inpatient settings.

METHODS: We conducted a study of patient-doctor communication on an inpatient medicine hospitalist service. A research assistant digitally recorded and transcribed daily doctor-patient dialogue on walk rounds and daily semi-structured interviews with patients and doctors separately. We audio-recorded 24 patient-doctor dialogues, representing 18 separate patient hospitalizations, as well as 24 corresponding interviews with hospitalists and 24 interviews with patients. The total recording time was 558 min. We used the OPTION-12 score, an instrument validated in the outpatient setting, to measure inpatient involvement in decision making in the hospital setting. One reviewer (ZB) used the instrument to score characteristics of shared decision-making in transcripts of audio-recorded patient-physician dialogues. The instrument was completed based on the completeness with which any one of 12 behaviors were found in any dialogue associated with the patient’s hospitalization. Any of these behaviors need only have been found once in any dialogue for it to be noted as present for that hospitalization.

RESULTS: The average OPTION-12 score per encounter was 5.3, compared to the mean of 16.9 in the original validation study by Elwyn et al. done in an outpatient setting. The minimum score was 2, and the maximum was 18. The mode was 4. The behavior among the OPTION-12 questions most commonly found in dialogue was giving the patient an opportunity to ask questions, found in 16 of 18 hospitalizations. Other common behaviors included the clinician’s asking the patient about their expectations or ideas about the management of the problem (12 of 18 hospitalizations), and asking the patient whether they understood the information given (13 of 18 hospitalizations). The behavior least often found was eliciting the patient’s preferred level of involvement in decision-making, which was not demonstrated in any hospitalization. Other uncommon behaviors included the clinician’s acknowledging that there was more than one legitimate management option (equipoise), and acknowledging the need to revisit the decision in the future (each found in 2 of 18 hospitalizations).

CONCLUSIONS: Patient involvement in decision making in the hospital setting varies and seems less common than in the outpatient setting. Further work should consider whether the domains measured by the OPTION are relevant to the inpatient setting, and if so, further explore their prevalence across inpatient settings and develop mechanisms to enhance patient involvement.

ORGANIZATIONAL FACTORS ASSOCIATED WITH MEDICATION ADHERENCE AFTER PATIENT CENTERED MEDICAL HOME TRANSFORMATION Nicholas Meo¹; Edwin Wong²; Christopher L. Bryson^{2,1}; Haili Sun²; Idamay Curtis²; Indra Gupta²; Adam Batten²; Stephan D. Fihn^{3,1}; Karin M. Nelson^{2,1}. ¹University of Washington, Seattle, WA; ²VA Puget Sound Health Care System, Seattle, WA; ³Veterans Health Administration, Seattle, WA. (Tracking ID #1938637)

BACKGROUND: Medication adherence is a complex process involving patient, medication, provider and health care delivery system. Primary care clinics throughout the Veterans Health Administration (VHA) adopted the patient-center medical home model, termed Patient Aligned Care Teams (PACT) in 2010. We wondered whether adopting a team-based model of care would be associated with changes in adherence

to medications for chronic disease. Objective: To compare clinic level adherence to oral hypoglycemic agents amongst veterans with diabetes at VHA primary care clinics nationally after implementation of PACT and to identify organizational correlates of adherence.

METHODS: Design: Retrospective cohort study. Participants: Patients with diabetes treated with oral hypoglycemic agents seen in VA hospital or community based primary care clinics in April to June 2012. Main Measures: 1 year refill based medication possession ratios (MPR) were calculated at the patient level. Clinic level adherence was defined as the proportion of patients within a clinic with >80 % MPR. Risk adjustment was performed to account for patient level demographic and comorbidities differences between clinics. A VHA-PACT Team Based Care survey and the Consumer Assessment of Healthcare Providers and Systems-Patient Centered Medical Home survey (CAHPS-PCMH) were used to identify organizational factors associated with OHA adherence. Multivariate linear regression was then performed on the results of clinic level survey data to identify organizational factors associated with clinic level adherence.

RESULTS: 440,971 patients with diabetes were included in the analysis at 757 primary care clinics (154 hospital based clinics and 614 community based clinics). Patients per clinic ranged from 100 to 5011. The overall average clinic level adherence was 58.56 %. Organizational factors associated with higher clinic-level adherence included provider continuity ($S\beta=.16$, $P<.001$), increased telephone based encounters ($S\beta=.13$, $P<.001$), regular medication reconciliation ($S\beta=.10$, $P<.05$), patient self report of enough time spent during encounters ($S\beta=.19$, $P=.005$), and delegation of tasks to a nursing care coordinator ($S\beta=.26$, $P<.005$).

CONCLUSIONS: Amongst a national cohort of veterans with diabetes, organizational characteristics central to the patient-centered medical home, including access, continuity, team-based care, patient-centered care, and care coordination were associated with better adherence to oral hypoglycemic therapy.

OUTCOMES OF A MULTI-DISCIPLINARY FALLS ASSESSMENT CLINIC

Vishal Reddy^{2,1}; Anne Vanderbilt¹; Barbara J. Messinger-Rapport¹. ¹Cleveland Clinic Foundation, Cleveland, OH; ²University of North Carolina, Chapel Hill, NC. (Tracking ID #1927947)

BACKGROUND: Falls create substantial morbidity and cost within a Patient Centered Medical Home (PCMH). The American and British Geriatric Society 2010 Guideline recommends screening for fall risk, and describes a multi-disciplinary assessment of older adults identified as at risk. The Guideline identifies interventions supported by Levels A & B evidence to reduce the risk of fall and fall-related injury. Typically, the evaluation process requires time and skills not available in the practitioner office at the time of the visit.

METHODS: The Cleveland Clinic PCMH developed a pilot Falls Clinic (FC) to provide a structured, 90-minute multidisciplinary assessment of adults 50 years and over. Assessment included screens for balance, strength, vision, fear of falling, cognition, mood, nutrition, and polypharmacy. The FC was staffed by a physical therapist (PT) and an advance practice nurse (APN). Cognitive screening was performed by a geriatric-trained nurse or medical assistant. The APN could initiate some referrals independently (such as home care, physical therapy or low vision occupational therapy) as well as testing (e.g. bone densitometry) and limited medication changes (vitamin D, for example). More substantive referrals, testing, or recommendations had to go through the PCMH practitioner. The PCMH practitioners were encouraged but not required to refer, and patients could self-refer. The Electronic Health Record (EHR) was used to collect demographic and clinically relevant information on FC clients prior to and after the FC visit. A follow-up phone call 3–6 months after the visit was used to gather additional clinical data not available in the EHR. Primary outcomes included recommendations and follow-through. Secondary outcomes included number of falls per patient and number of fallers before and after the intervention. Analysis was descriptive. The protocol was approved by the IRB.

RESULTS: Of the 74 new FC patients between June 2012 and May 2013, there were 42 whose data could not be included in the final data set either because the minimum 3 months past the visit had not occurred, or because after 3 tries we were unable to reach the patient or care partner by phone. Of the 32 new FC patients for whom a complete data set was available, the average age (sd, range) was 79.3(8.4, range 66–93) years. Average number of medications (sd, range) was 11.2(4.8, 2–25). We compared demographic and clinical information with the FC patients who could not be included in the final data set and there were no significant differences. The average number of falls per patient prior to the FC (sd, range) was 3.0 (2.81, 0–12). The most common recommendations

and the percent of patients who followed through are listed in the Table. 23/32 attendees of the FC had fewer falls in the 6 months after the appointment than prior including 16 patients eliminating falls completely. Of the 4/32 patients without falls prior to their appointment, none fell after their appointment. Of the 28/32 patients who fell prior to the FC visit, only 12/28 fell after the FC visit. The average number of falls in the 6 months prior to the appointment was 2.97 versus 0.28 in the 6 months following the appointment.

CONCLUSIONS: A multidisciplinary, guideline driven falls clinic can support a PCMH to offer evidence based interventions to reduce the risk of falls. Future steps involve efforts to improve compliance with recommendations and expanding referrals via care pathways in the PCMH.

Recommendations from the Falls Clinic

INTERVENTION	FREQUENCY RECOMMENDED n(%)	FREQUENCY OF FOLLOW-THROUGH n(%)
Physical Therapy	26 (81.3 %)	16 (61.5 %)
Exercise	23 (71.9 %)	11 (47.8 %)
Vitamin D	15 (46.9 %)	11 (73.3 %)
Ophthalmology	15 (46.9 %)	8 (53.3 %)

OVARIAN CANCER TREATMENT AND SURVIVAL TRENDS OVER PAST DECADE Jenny J. Lin¹; Natalia Egorova²; Rebeca Franco²; Nina A. Bickell^{1,2}.

¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Icahn School of Medicine at Mount Sinai, New York, NY. (Tracking ID #1939426)

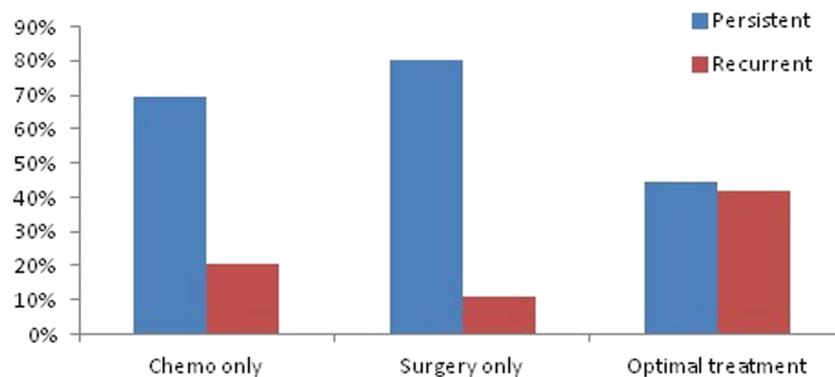

BACKGROUND: While death rates from ovarian cancer appear to be decreasing and five-year survival rates are increasing, it is unclear whether overall survival is improving among women with advanced ovarian cancer. We undertook this study to assess trends of overall survival, cancer recurrence and treatment patterns among women with advanced stage ovarian cancer.

METHODS: Using SEER-Medicare claims data from 2000 to 2009, we identified a cohort of women age 65+ years with Medicare diagnosed with stage III and IV epithelial ovarian cancer. Recurrent cancer was identified using claims for chemotherapy, hospice or secondary cytoreductive surgery following a 6 month treatment-free window after primary treatment for ovarian cancer. Persistent cancer was defined as receipt of treatment (surgery or chemotherapy) without a treatment-free window of at least 6 months. Optimal treatment was defined as surgery within 120 days of diagnosis followed by chemotherapy within 120 days of initial surgery. Survival time was calculated from time of diagnosis. Parametric and semi-parametric multivariate survival analyses were used to assess comparative treatment survival rates and factors affecting survival and recurrence.

RESULTS: Of the 46,004 women with ovarian cancer, 6,814 met the study criteria. Of these, only 3,413 women (50 %) underwent primary debulking surgery and chemotherapy in an optimal time frame, 970 (14 %) received surgery alone and 1,799 (26 %) received chemotherapy alone, 214 received no treatment and 418 did not receive surgery and chemotherapy in an optimal time frame. During the past decade, overall median survival time remained relatively constant, although the time to first recurrence increased by 260 days and the probability of having a recurrence grew from 2000 to 2004 and stabilized during 2005–2009. Ovarian cancer was the cause of death for 85 % of women diagnosed in 2000 and 72 % for those who diagnosed in 2008. Optimal treatment was associated with longer survival time ($p<0.001$, median survival 1,411 days), a lower proportion of persistent cancers and higher proportion of patients with recurrences (see figure). Survival of patients receiving optimal treatment improved over the decade, while for those who received chemotherapy or surgery alone, survival probability did not change. However, the proportions of women who received optimal treatment versus other treatments did not vary over time. Multivariate survival models controlling for patient demographics, cancer type and comorbidities showed that patients who received optimal primary treatment or who had multiple recurrences had longer survival but there were not substantial changes in overall survival during the last decade. Propensity analyses are underway.

CONCLUSIONS: Among elderly women diagnosed with advanced stage ovarian cancer, patterns of overall survival and treatment types have not changed in the past decade. Optimal cancer treatment is associated with improved survival time. Further work should evaluate barriers to receipt of optimal treatment among this group of patients.

Cancer outcome by primary treatment type

OVER A DECADE OF DUTY HOURS: WHO DO PATIENTS SAY IS MOST INVOLVED IN THEIR HOSPITAL CARE? Vineet Arora; Micah Prochaska; Jeanne M. Farnan; David Meltzer. University of Chicago Medical Center, Chicago, IL. (Tracking ID #1938094)

BACKGROUND: Internal medicine residency training is grounded in experiential learning, or having residents assume care for a set of patients. With implementation of residency duty hours over the past decade, many believe that attending physicians are responsible for a greater portion of patient care and resident education has suffered. Studies to date have largely ignored the patient perspective. Changes over time in hospitalized patients' perceptions of who is most involved in their hospital care may provide a useful measure of whether roles of resident and attending physicians have changed since implementation of successive duty hour restrictions over the past 12 years.

METHODS: From 2001 to 2013, all general medicine inpatients cared for on the housestaff teaching service at a single academic center were approached for an admission interview and a 30 days post-discharge phone interview. Each patient had a primary team consisting of an intern, resident (PGY2 or 3), and attending physician. Thirty-days after discharge, patients were asked to answer, "Who was most involved in their hospital care?" and were given the options of attending, resident, intern, medical student, nurse, other, or I don't know. Routine demographics (age, gender, race) were obtained from chart review. Time periods were categorized by duty hour restrictions as pre-2003, post2003-pre2011, and post-2011. Chi square tests were used to assess associations between demographics, duty hour period, and whom patients named as involved in their care. Multinomial logistic regression was used to test the proportional odds of naming a specific person compared to the attending during the duty hour periods controlling for patient demographics and whether inpatient attending was a hospitalist or not.

RESULTS: From July 2001 to June 2013, 39,469 patients were admitted to the teaching service at a single academic medical center. Of these, 22,750 (58 %) could be reached by phone 1 month after discharge. Overall, 29 % did not know who was most involved, followed by 28 % listed the attending, 11 % resident and 6 % intern. The percentage of patients who identified their attending as most involved in their care increased with increasing duty hours restrictions (pre2003 20 %, post2003-pre2011 29 %, post2011 37 %, $p<0.001$). With successive duty hour restrictions, the percentage of patients who listed an intern declined in each period (pre2003 9 %, post2003-pre2011 6 %, post2011 3 %, $p<0.001$) as did the percentage who named any housestaff (resident or intern) (pre2003 20 %, post2003-pre2011 17 %, post2011 12 %, $p<0.001$). The percentage of patients who responded "I don't know" decreased with restricted duty hours decreased after 2011 (pre2003 32 %, post2003-pre2011 30 %, post2011 22 %, $p<0.001$). These associations were not affected by whether the inpatient attending was a hospitalist or not, and they remained significant in multinomial logistic regression.

CONCLUSIONS: The percentage of patients on general medicine teaching services who listed their attending as most involved in their care has more than doubled with successive resident duty hour restrictions over the past 12 years. Given the importance placed on achieving progressive levels of independence in assuming responsibility for patient care during residency, efforts should be undertaken to understand the implications for these findings for residency competence and patient care.

OVERDOSE EDUCATION AND NALOXONE PRESCRIBING FOR PATIENTS ON CHRONIC OPIOIDS: A QUALITATIVE STUDY OF HEALTH CARE PROVIDERS Ingrid A. Binswanger^{1,2}; Steve Koester^{3,4}; Shane Mueller^{1,3}; Edward M. Gardner²; Kristin Goddard⁵; Jason M. Glanz⁵. ¹University of Colorado School of Medicine, Denver, CO; ²Denver Health Medical Center, Denver, CO; ³University of Colorado Denver, Denver, CO; ⁴University of Colorado Denver, Denver, CO; ⁵Kaiser Permanente Colorado, Denver, CO. (Tracking ID #1928545)

BACKGROUND: Fatal unintentional poisonings from pharmaceutical opioids have increased nearly four-fold in the last decade. Naloxone is an effective, Food and Drug Administration approved opioid antidote usually administered by first responders to reverse respiratory depression due to opioid poisoning. Increasingly, community-based programs have provided naloxone to heroin users for potential overdose reversal. Patients on chronic pharmaceutical opioids for pain could also benefit from overdose education and naloxone prescription, but there are significant barriers to these practices in routine clinical care. This qualitative study was designed to assess the knowledge, attitudes and beliefs about overdose prevention and naloxone prescription among primary care and HIV clinicians, pharmacists and clinic administrators.

METHODS: We conducted focus groups in two primary care internal medicine and two infectious disease/HIV clinics from a university and a safety net health system in Colorado, a state which passed legislation to permit naloxone prescriptions in 2013. A focus group guide was developed using domains from the Theory of Planned Behavior and the Health Belief Model. Each focus group was led by two experienced qualitative interviewers. Focus groups were recorded and transcribed, coded using ATLAS.ti® qualitative software, and analyzed using a team-based constant comparative method of inductive analysis.

RESULTS: We enrolled 10 (40 %) physicians, 6 (24 %) nurses, 4 (16 %) pharmacists, 3 (12 %) nurse practitioners, 1 (4 %) administrator, and 1 (4 %) counselor into focus groups. Fourteen (56 %) participants were female and participants had a mean age of 42 years (range 26–58 years). Eighteen (72 %) were white, 3 (12 %) were Hispanic or Latino, 2 (8 %) were African American, and 2 (8 %) were Asian. Participants described opioid overdoses among their patients and several formal and informal opioid prescribing policies and guidelines, but little prior knowledge and uptake of overdose education and naloxone prescribing in clinical practice. We identified the following themes from the transcripts (see Table for illustrative quotations): 1) A wide spectrum of patients could be targeted for naloxone prescription, including patients with concomitant mental health problems, impulsivity, and poorly controlled pain; 2) Barriers and challenges to implementation of a naloxone prescription fell into two major categories: attitudinal and practical. Providers were concerned about giving mixed messages about opioid safety (attitudinal) and adding training to administer naloxone to an already busy clinic schedule (practical). 3) The benefits of naloxone prescribing were perceived as significant. They included direct benefits such as preventing accidental overdose, as well as indirect benefits, such as alerting patients and their significant others to the overdose potential of opioids and enhancing medication safety.

CONCLUSIONS: Health care providers had limited awareness about naloxone for take-home use but were receptive to prescribing it to a broad range of patients on opioids for pain. Providers also identified a number of potential safety benefits to naloxone prescribing. However, efficiency concerns and ambivalence about prescrib-

ing opioids to patients who could overdose limited enthusiasm for naloxone. To address opioid overdose risk in clinical practice, future efforts should enhance provider knowledge on overdose education and naloxone prescription, reduce implementation barriers, and improve opioid safety messaging for patients on chronic opioids.

Emerging themes and illustrative quotations about overdose education and naloxone prescribing in clinical practice

Patients to target for naloxone	“I think the patients on the maximum dose are a good place to start, but I think that’s not... those aren’t the only people at risk for overdose and in fact those are probably the most tolerant of all our patients... I had a patient whose daughter accidentally overdosed on her meds... so, I’m wondering, shouldn’t we be offering it more broadly...?”
Practical barriers to naloxone prescribing	“But the idea that you teach the person that’s taking the narcotics and relying on them to teach the other person is kind of a limiting factor in how successful it is...” “...but I do think it would be tough in sort of a general... to have all the providers in this clinic learn about naloxone and teach it during their regular clinic hours.”
Attitudinal barriers to naloxone prescribing and reservations about naloxone	“It seems kind of intuitive, like glucagon for insulin. It’s kind of intuitive.... But it just feels a little uncomfortable. You know, it just feels a little uncomfortable where glucagon just doesn’t... It seems like it may have merit. On some level it also makes me feel like it’s sort of putting our head in the sand just a little bit, you know. If you feel like, my God, this patient is going to kill themselves. Maybe the solution is to not have them on opioids.”
Benefits of naloxone	“I was sort of hoping that if we implement a good program where even at initiation, we talk about overdose prevention and naloxone that it will bring, you know, the safety concerns to the forefront and then it might actually help people understand that these are potentially lethal medications and I feel like that might be one of the things that might be most beneficial from it is just re-setting of like the culture around these medications as much as, you know, potentially saving someone’s life from overdose.”

PANEL MANAGEMENT IN PRIMARY CARE: A SYSTEMATIC REVIEW

Ashley E. Jensen³; Nicole Skursky³; Matthew Beyrouty³; Katelyn Bennett^{1,3}; Mark D. Schwartz^{1,2}; Scott Sherman^{1,2}. ¹VA New York Harbor Healthcare System, New York, NY; ²NYU School of Medicine, New York, NY; ³NYU School of Medicine, New York, NY. (Tracking ID #193751)

BACKGROUND: Panel management is a set of processes and tools for proactively preventing and managing chronic illness in populations of patients, at the level of the primary care panel. It is widely promoted as a component of the patient-centered medical home model. Panel management strategies are still being developed and tested, and have not yet been widely adopted in primary care in the United States. We sought to review the range of panel management strategies tested and assess the effectiveness of panel management interventions in improving primary care processes and clinical outcomes. We used this review to establish a research agenda to advance our understanding of panel management in primary care.

METHODS: A systematic review was conducted utilizing data sources from Ovid Medline, PubMed, Web of Science, and CINAHL from 1990 through January 2014. Study selection included English language trials and longitudinal observational studies that met our criteria for panel management (proactive outreach, conducted in primary care, and use of clinical data). The core search strategy used in each database was (“Population Management” OR “Panel Management”) AND “Primary Care.” We extracted data on study design, population, interventions, outcomes, cost, and risk of bias. Two investigators independently abstracted the data to enhance reliability. In the

case of disagreement a third author reviewed the study in question to reach consensus. Using the Cochrane tool, a risk of bias assessment was conducted to verify the studies’ results and to determine if the level of bias was adequate (low) or not adequate (high) across 6 domains.

RESULTS: A total of 87 articles describing unique studies were identified, of which 27 met the inclusion criteria. Of these 27 studies, 17 were randomized controlled trials and 10 were controlled cohort studies, targeting a range of illnesses (e.g. diabetes, various cancers, and heart disease), both primary and secondary prevention, and various care processes (e.g. screenings, labs, appointments) through a variety of panel management approaches (e.g. provider focused, mailed reminders, adding team members). All studies reported significant improvements over usual care or comparison groups, though effect sizes were modest. For instance, 3 out of 4 diabetes studies reported significant improvements in glycemic control (HbA1c) for panel management intervention groups with decreases ranging from 0.3 to 1.07 % over controls and Colorectal cancer screening rates increased significantly (11.0 % to 19.0 % over control) with panel management in all 5 studies reporting screening rates. Only 5 studies undertook any cost-effectiveness analysis; of these 2 reported annual costs per patient ranging from \$24 to \$464, 2 reported net cost savings (3.6 % to 11 % per patient), and 1 reported no significant savings. The risk of bias was low among the 17 RCTs across most domains, with the predominant risks stemming from the lack of blinding of group assignment and insufficient evidence to determine if there was selective outcome reporting.

CONCLUSIONS: Panel management holds promise for prevention and management of chronic illness within the patient-centered medical home. However, current evidence is insufficient to determine the effects on clinical and economic outcomes. While many of the studies have shown a modest benefit, their heterogeneity to date prevents a definitive conclusion about effect size or ideal approach. This emerging and potentially disruptive innovation in primary care practice needs further research to clarify terms and to cohere around effective and efficient models.

PAP VS. HPV VS CO-TEST FOR CIN2+ DETECTION: A RETROSPECTIVE STUDY OF PERFORMANCE AND COST

Andrea L. Sikon¹; Xian W. Jin¹; Laura D. Lipold²; Sarah Schramm³; Kelly Nottingham³; Bo Hu⁴; Michael B. Rothberg^{1,3}. ¹Cleveland Clinic, Cleveland, OH; ²Cleveland Clinic, Cleveland, OH; ³Cleveland Clinic, Cleveland, OH; ⁴Cleveland Clinic, Cleveland, OH. (Tracking ID #1936679)

BACKGROUND: Existing cervical cancer screening guidelines allow for two options for women aged 30 and older: pap every 3 years (with reflex testing for HPV when cytology shows ASCUS) or pap and HPV co-testing every 5 years. Some is known about the performance of these two strategies but comparisons of cost are even more limited. To understand the performance of existing as well as a novel strategy (i.e. initial HPV screening with reflex pap if positive,) we compared the expected costs per case of cervical intraepithelial neoplasia 2 or worse (CIN2+) detected by these strategies amongst a large cohort of women.

METHODS: A retrospective chart review was performed of all women 30 years or older who had primary screening with both HPV and cervical cytology (i.e. co-testing) during the same encounter at the Cleveland Clinic from 2004 to 2010. A pathology database was utilized to identify biopsy-proven CIN2+ cases. Information on age, race, marital status, insurance type, and smoking history was also collected. For women who had abnormal screening tests but did not have documented colposcopy results, we performed data imputation based on co-testing results. Sensitivity, specificity, positive and negative predictive values were estimated for 3 strategies: Pap with reflex HPV, HPV with reflex pap and co-testing. For each strategy we calculated costs based on the number of HPV tests, pap tests and coloscopies that would be performed.

RESULTS: The dataset included 99,549 women who had simultaneous cytology and HPV collected during the study period. Subjects were mostly white (78.4 %), married/domestic partner (70.7 %), nonsmokers (61.3 %) and with private insurance (86.1 %). Overall, 5121 subjects (5.14 %, 95 % CI=[5.01 %, 5.28 %]) were infected with HPV and 6115 (6.14 %, 95 % CI=[5.99 %, 6.29 %]) had cytology that demonstrated ASCUS or worse. Of these, 1,347 underwent colposcopy, and 605 subjects (0.61 %, 95 % CI=[0.56 %, 0.66 %]) had CIN2+. An additional 709 women had a combination of HPV+ and ASCUS or higher on cytology but did not have documented colposcopy results. Of these women, 183 had CIN2+ assigned by imputation, for an overall expected incidence rate of CIN2+ of 0.79 % (95 % CI=[0.74 %, 0.85 %]). Sensitivity for CIN2+ was 89.9 % for cytology, 94.0 % for HPV and 97.7 % for co-testing; specificity was 97.7 % for cytology, 98.3 % for HPV and 97.7 % for co-testing. The negative predictive value was 99.92 % for cytology alone, 99.95 % for HPV alone and 99.98 % if both tests were negative. Pap with reflex HPV was least expensive, costing \$31.6 M and detecting 708 cases of CIN2+,

with 2965 colposcopies per 100,000 women screened. HPV with reflex pap would detect an additional 33 cases of CIN2+, and require 508 fewer colposcopies, at a marginal cost of \$11.3 M, or \$342 K per additional case detected. Compared to HPV with reflex pap, co-testing would detect an additional 29 cases, and require an additional 570 colposcopies, at a marginal cost of \$21.2 M or \$732 K/case. The marginal cost per case would be higher in lower risk populations and vice versa.

CONCLUSIONS: Screening women using HPV initially rather than pap could detect slightly more cases of CIN 2+ at a marginal cost of \$342 K/case in this large cohort. Co-testing all patients could detect even more cases, but at a marginal cost of \$732 K/case. Acceptable thresholds of additional cost per case to capture a relatively small number of additional cases are currently lacking and further cost effectiveness studies should be considered. In this era of value based care and personalized health care, considerations of varied screening strategies according to individual risk as well as to cost per case is necessary. More sophisticated assessment of risk may help to better modify recommended screening methods and intervals and allow for concentration of more costly resources on those at highest risk while still providing sound screening for those at lower risk.

PARATHYROID HORMONE SUPPRESSION AND INCIDENT HEART FAILURE Derar Albasheireh¹; Kawanjit Sekhon⁴; Mona Hassan¹; Laila Shiekh Sroujeh¹; Meghan G. Liroff²; Waqas Qureshi³. ¹Henry Ford Hospital, Detroit, MI; ²Henry Ford Hospital, Detroit, MI; ³Wake Forest University, Winston-Salem, NC; ⁴Wayne State University, Detroit, MI. (*Tracking ID #1934393*)

BACKGROUND: Secondary hyperparathyroidism is frequently common in patients with chronic kidney disease. Suppression with medications is frequently attempted to prevent accelerated bone loss. However, it is not known if this can decrease the incidence of heart failure.

METHODS: An incident case - control study was performed with cases defined as Stage 3–5 chronic kidney disease (CKD) patients with parathyroid hormone (PTH) levels managed within target levels per National Kidney Foundation guidelines for at least 3 years (CKD stage 3; 35–70 pg/ml, stage 4; 70–110 pg/ml, stage 5; 150–300 pg/ml). Controls were age, gender and race matched and defined as Stage 3–5 CKD patients with <50 % of the times, PTH levels managed within target levels as given above. Conditional multivariate analysis was performed to evaluate the differences between incidences of heart failure. Time to event analysis was performed for heart failure admissions. Echocardiographic evaluation prior to enrollment in the study and after at least 3 years of control in the study were evaluated to define systolic heart failure (left ventricular ejection fraction <50 %) and diastolic heart failure defined based on American society of echocardiography definition.

RESULTS: There were 243 cases (mean age 66.3±13 years, women 60.3 %, whites 58.2 %) and 243 controls. Cases were similar in proportion of hypertension, diabetes, previous history of myocardial infarction, There were 38 systolic heart failure (EF <50 %) and 59 diastolic heart failure in controls, while there were 23 systolic heart failure and 76 diastolic heart failure in cases over a period of 6.3±2.4 years of follow up. Cases were more likely to develop incident systolic and diastolic heart failure ($p<0.01$). Predictors of incident heart failure include previous history of diastolic dysfunction (OR 2.45; 95 % CI 1.33–2.95, $p=0.0008$), diabetes mellitus (OR 1.45; 95 % CI 1.12–1.84, $p=0.005$), and previous history of myocardial infarction (OR 1.94; 95%CI 1.28–2.53, $p=0.007$).

CONCLUSIONS: In conclusion, maintaining parathyroid hormone within target limits was associated with decrease in incident heart failure in our study. This may be explained by known role of parathyroid hormone in pathophysiology of heart failure.

PARTICIPATION OF MEDICAL STUDENTS IN TRANSITIONS OF CARE: A NEEDS ASSESSMENT Lauren Block^{1,2}; Melissa Morgan-Gouveia^{3,4}; Danelle Cayea⁴. ¹Hofstra North Shore-LIJ School of Medicine, New Hyde Park, NY; ²Bloomberg School of Public Health, Baltimore, MD; ³Christiana Care Health System, Newark, DE; ⁴Johns Hopkins University School of Medicine, Baltimore, MD. (*Tracking ID #1936831*)

BACKGROUND: As residents are expected to be competent in transitions in care, training in effective transitions must begin in medical school. The Liaison Committee on Medical Education (LCME) cites effective communication and care across the continuum as key skills for trainees. However, medical students report knowledge gaps related to the discharge process. While several medical schools offer curricula on safe transitions of care, formal education on this topic is not universal. We sought to understand the frequency of participation, learning, and independence in transitions in care among third and fourth year medical students.

METHODS: We conducted a cross-sectional survey of third and fourth year students at four medical schools in the mid-Atlantic region. Private, public, and military schools were represented. Students were invited to participate in an electronic survey regarding participation in patient discharges on their medicine clerkship, teaching about discharge skills, independence completing discharge tasks, and additional training desired. IRB approval was obtained at all institutions.

RESULTS: A total of 358 students from the four medical schools completed the survey (response rate = 44 %). 110 (31 %) were third year and 246 (69 %) were fourth year students. 246 (69 %) reported having completed at least one sub-internship. Most students reported participating in discharge tasks with the majority of their patients, including educating patients at discharge (87 %), reconciling medications at discharge (81 %), collaborating with a multidisciplinary team (73 %), identifying barriers to discharge (73 %), and writing discharge instructions (69 %). Fewer students reported writing discharge summaries (66 %) and communicating with the primary care physician (29 %) regularly. Fourth year students were more likely than third year students to report identifying barriers to discharge (76 % vs. 64 %, $p=0.02$), reconciling medications at discharge (94 % vs. 85 %, $p<0.01$), educating patients at discharge (90 % vs. 81 %, $p=0.02$), reviewing discharge instructions with patients (58 % vs. 46 %, $p=0.03$), communicating with the primary care physician (35 % vs. 17 %, $p<0.01$), and collaborating with the multidisciplinary team (80 % vs. 56 %, $p<0.01$) with the majority of patients. Most students (96 %) reported that residents taught them these skills; only 28 % were taught by attending physicians, and 49 % reported being self-taught. Most students reported independence in reviewing discharge instructions with patients (58 %) and collaborating with the multidisciplinary team (50 %), but fewer than 50 % reported independence in the remaining discharge skills. Students who completed at least one sub-internship reported higher levels of independence in all skills except writing discharge summaries. Students who learned these skills from attending physicians reported more independence in identifying barriers to discharge, writing discharge instructions and summaries, communicating with primary care physicians, and collaborating with multidisciplinary teams. Ninety-seven percent of students reported that additional training in discharge skills would be helpful for their education.

CONCLUSIONS: In a multi-institution sample, most students reported participation in discharge tasks with their patients on the medicine clerkship. Many educational programs prioritize teaching these skills during a subinternship or internship. However, the majority of 3rd year students are involved in tasks related to discharge. Students did not feel fully independent completing these tasks, and the majority reported that additional training would be helpful. While students who learned discharge skills from attending physicians were more likely to report independence in some of these skills, students were more likely to report learning these skills from residents than from faculty, suggesting that formal teaching may be valued by students. Students reported communicating with primary care physicians and reviewing discharge instructions with patients less frequently than other tasks, indicating priority areas for future curricula.

PATIENT ACTIVATION INTERVENTION IMPROVED EVIDENCE-BASED MEDICATION USE IN DIABETIC AND HEART DISEASE PATIENTS IN FEDERALLY QUALIFIED HEALTH CENTERS: THE OFFICE GUIDELINES APPLIED TO PRACTICE PROGRAM Ade B. Olomu¹; Bikki Gautam¹; Bethany Buda¹; Wei-Wen Hsu³; Gurpreet Chahal¹; Janaki Samaraweera¹; Haritha Machavarapu¹; Wendy Uwaje¹; David Todem²; Margaret Holmes-Rovner⁴. ¹Michigan State University, East Lansing, MI; ²Michigan State University, East Lansing, MI; ³Michigan State University, East Lansing, MI; ⁴Michigan State University, East Lansing, MI. (*Tracking ID #1933143*)

BACKGROUND: Many studies have documented suboptimal treatment for cardiac outpatients, especially for minority and low-income population. Despite the well documented efficacy of aspirin, Beta Blockers, statins and angiotensin-converting enzyme inhibitors (ACEIs), appropriate use and adherence to these therapies remains a concern in patients attending Federally Qualified Health Centers (FQHCs). Patient activation/engagement is an increasingly important component of strategies to improve outcomes for patients and reform health care. Objectives: 1) determine the impact of a patient activation intervention on guidelines based medication use for diabetic and heart disease patients in FQHCs 2) determine the predictors of medication use.

METHODS: The Office Guidelines Applied to Practice (Office-GAP) study is a two-center study designed to improve cardiovascular care for minority and low-income populations in outpatient clinical settings. Clinics were assigned to intervention or control arm by tossing the coin. Office-GAP intervention included: 1) Patient activation /engagement intervention during a group visit 2) Physician training for

patient activation/engagement and 3) Decision support/Checklist intervention (DSI) used in real time in the office. After a group visit, patients followed up with 2 physician visits using GAP tools. We performed chart abstraction of all enrolled patients with cardiovascular disease (CVD) and Diabetes Mellitus (DM) from September 2010 to Dec 2012 in 2 FQHCs. Logistic Regression analysis was used to examine change over time in the proportion of patients using Aspirin/Plavix, ACEIs /ARBs, beta-blockers and statins.

RESULTS: Of 242 patients studied, 100 patients were in the intervention (Office-GAP) arm and 142 in the control arm. The control group showed no difference between baseline and 6 months medication use, while the intervention group showed the use of ACEIs/ARBs as (58.62 % vs. 63.22 %); Aspirin/Plavix (67.74 % vs. 96.77 %), Beta-blocker (60.00 % vs 71.43 %) and statin (62.78 % vs. 80.52 %) respectively. Longitudinal logistic regression revealed Office-GAP intervention significantly increased the use of ACEIs/ARBs for all eligible patients at 3 months (OR 3.93, $p=0.001$), Aspirin/Plavix (OR 2.43, $p=0.046$) at 6 months compared to control. Predictors of medication use included age, {ACEIs/ARBs (OR=1.03, $p=<0.001$), Aspirin/Plavix (OR=1.04, $p=<0.001$), Beta Blocker (OR=1.02, $p=0.042$) and statins (OR=1.03, $p=<0.001$) and Charlson Index {ACEIs/ARBs (OR=1.28, $p=<0.001$), ASA/Plavix (OR=1.4, $p=<0.001$), Beta Blocker (OR=1.84, $p=<0.001$) and statins (OR=1.38, $p=<0.001$ }. Whites were more likely to be on ASA/Plavix at baseline, 3 months and 6 months compared to Blacks (OR=1.78 $p=0.011$). Furthermore, patients that completed all 3 Office- GAP visits were more likely to be on ASA/Plavix (OR=1.73, $p=0.022$) compared to patients that completed only one or two Office-GAP visits.

CONCLUSIONS: This Patient Activation Program led to increased use of guidelines based medications for patients with CVD and DM in FQHCs. We found that white patients were more likely to be on aspirin. Age and higher comorbidity predicted increased medication use. The Office-GAP program could serve as a model for implementation of guideline-based care for chronic diseases in outpatient clinical settings. Further study is needed to establish reach, effectiveness, and cost-effectiveness.

PATIENT ACTIVATION MEASURE AND CARE TRANSITIONS AMONG SOCIOECONOMICALLY VULNERABLE ADULTS Devan Kansagara^{2,3}; Molly McClain^{1,5}; Honora Englander²; Dawn Peters¹; Cynthia D. Morris⁴. ¹Oregon Health & Science University, Portland, OR; ²Oregon Health & Science University, Portland, OR; ³Portland VA Medical Center, Portland, OR; ⁴Oregon Health & Science University, Portland, OR; ⁵University of New Mexico, Albuquerque, NM. (*Tracking ID #1937165*)

BACKGROUND: The Patient Activation Measure (PAM) quantifies patients' confidence, skills, and knowledge in regards to managing their own health. Higher levels of activation have been linked to improved health behaviors and health outcomes, and lower health care utilization. Little is known, however, about the use of the PAM during times of care transitions, or in socioeconomically disadvantaged adults, many of whom face poverty and other barriers to accessing care after hospital discharge. We performed this study to explore 1) whether baseline patient activation predicted readmission risk, and 2) whether an intervention that improved patients' access to care and ability to self-manage care post-discharge might impact patient activation scores.

METHODS: The study is a secondary analysis of data collected in the Care Transitions Innovation (C-TraIn) study. C-TraIn included 382 uninsured and low-income publicly insured adults admitted to general medicine or cardiology inpatient services at a single urban academic medical center in Portland, Oregon. Participants resided in one of three Portland metro area counties, had access to a working phone (friend or shelter phone was okay), spoke English, and had no disabling mental illness (defined as active psychosis or active suicidal ideation). Participants were randomized to receive usual care, or usual care plus C-TraIn, which included (1) transitional nurse coaching and education, often including home visits for highest risk patients; (2) pharmacy care, including provision of 30 days of medications after discharge for those without prescription drug coverage; (3) post-hospital primary care linkages, including establishing new outpatient linkages for those without a usual source of care; and (4) systems integration and continuous quality improvement. Participants were enrolled early in hospitalization and completed a baseline survey with blinded researchers that included the Patient Activation Measure (PAM). The survey was repeated by phone 30 days after discharge. Readmission data for all participants, including the uninsured, were obtained using a hospital administrative database that includes admissions from all Oregon and southwest Washington hospitals. We used regression analysis to determine 1) if PAM scores assessed early in hospitalization predicted 30-day readmission, and 2) if there was a difference in PAM scores among

C-TraIn compared to control patients. We hypothesized that low baseline PAM scores would be associated with higher readmission rates. To measure this, baseline PAM scores were dichotomized as "low" (PAM levels 1 and 2, scores 1–55.1), and "high" (PAM levels 3 and 4, scores of 55.2–100). Odds of readmission comparing low and high baseline PAM were calculated using univariable logistic regression, followed by multivariable logistic regression controlling for clinically relevant covariates, including race, gender, trouble taking medication, depression, illness severity (Charlson index) and social support. We included an interaction between allocation group and baseline PAM score to allow for the possible differential effect of the C-TraIn intervention on the relationship between baseline PAM scores and readmission. We also hypothesized that the C-TraIn intervention would improve patient activation relative to usual care. We compared the 30-day mean change in PAM score between the allocation groups using Student's t test and followed this by linear regression analysis adjusted for the same covariates as above.

RESULTS: 382 patients enrolled in the C-TraIn study; 209 were allocated to the intervention group and 173 to the control. All 382 completed baseline surveys. 293 (74 %) completed 30-day post-discharge survey, and of these, 254 had complete baseline and post-discharge PAM surveys. Multivariable logistic regression modeling revealed the odds of 30-day readmission was roughly 40 % less for those with high PAM scores [OR: 0.57, 95 % CI: 0.34–0.96, P-value: 0.04] compared to those with low PAM scores. This association was adjusted for race, gender, severity of illness, depression, and social support. Multivariate linear regression modeling, controlling for the same covariates, demonstrated that participation in the Care Transitions Innovation did not affect a change in PAM scores compared to the control group [B-coefficient: -1.06, 95%CI: -4.36–2.11, P-value: 0.52].

CONCLUSIONS: Low baseline PAM scores were associated with higher rates of 30-day readmission, suggesting PAM may be useful in predicting risk of readmission in socioeconomically vulnerable adults. However, PAM scores did not improve in participants who received an intervention that improved transitional care quality and enhanced access to post-discharge care.

PATIENT AND PROVIDER PERCEPTIONS OF THE PATIENT CENTERED MEDICAL HOME: AGREEMENT AND TENSIONS Shreya Kangovi^{1,2}; Katherine Kellom⁴; Christopher Sha⁵; Sarah Johnson⁶; Casey Chanton²; Tamala Carter^{1,4}; Judith A. Long^{3,1}; David Grande^{1,7}. ¹University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA; ²University of Pennsylvania Health System, Philadelphia, PA; ³Philadelphia Veterans Affairs Medical Center, Philadelphia, PA; ⁴University of Pennsylvania, Philadelphia, PA; ⁵University of San Francisco, San Francisco, CA; ⁶Johns Hopkins Hospital, Baltimore, MD; ⁷University of Pennsylvania, Philadelphia, PA. (*Tracking ID #1939665*)

BACKGROUND: Six years into the movement of Patient-Centered Medical Home (PCMH)-driven primary care redesign, the evidence for its impact on patient and caregiver experience is mixed. Our objective was to explore areas of agreement and tension between the perceptions of high-risk patients and their practice staff on PCMH principles and implementation strategies.

METHODS: We conducted qualitative in-depth, semi-structured interviews with chronically-ill, uninsured or Medicaid patients from low-income Philadelphia ZIP codes ($n=21$), and their primary care practice staff ($n=30$). We included patients and staff of three practices (two academic and one federally qualified health center).

RESULTS: We observed three key findings. First, while staff were enthusiastic about enhancing access through strategies like online communication and open access scheduling, low-income patients viewed these as access barriers and preferred telephone encounters. Second, both patients and staff described a common tradeoff: timely care from an unfamiliar provider versus delayed access to their personal physician. Participants viewed small, multi-disciplinary teams as a potential strategy for reconciling the tension between access and continuity. Third, practices have re-engineered appointment systems to create slots for unscheduled acute care. Yet, they lacked capacity to manage higher acuity conditions that tended to fill these appointments. As a result, these patients were frequently referred to the emergency room.

CONCLUSIONS: High-risk patients and primary care staff highlighted tensions raised by the PCMH principles and suggested approaches to reconcile those tensions.

PATIENT EXPERIENCES OF AND PREFERENCES FOR ACCESS AND CONTINUITY OF CARE IN A PATIENT-CENTERED MEDICAL HOME Jane Forman¹; Molly Harrod¹; Claire Robinson¹; Ann-Marie Rosland^{1,2}; Leo Greenstone^{1,2}; Adam Tremblay^{1,2}; Eve A. Kerr^{1,2}. ¹VA Ann Arbor Healthcare System, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI. (*Tracking ID #1938328*)

BACKGROUND: Two central measures of success of a patient-centered medical home are increasing timely access to primary care (PC) and continuity of care with the patient's primary care provider (PCP). Compliance with the National Committee for Quality Assurance PCMH and the Centers for Medicare & Medicaid ACO quality standards require practice-level evaluation of access and continuity measures. In its medical home initiative, Patient Aligned Care Teams (PACT), the Department of Veterans Affairs (VA) has emphasized improving access and continuity, and set key metrics for same-day requests with the patient's assigned PCP (access), and the proportion of encounters completed with the patient's assigned PCP (continuity). Although measures of access and continuity are built on assumptions about patient preferences, little is known about these preferences and patient experiences. We conducted in-depth qualitative interviews of PC patients in a large VA academic medical center to identify factors that affect where patients choose to seek same-day care (in PC or urgent care), and what influences whether patients prioritize continuity with their usual PCPs vs. short-term access to any PCP.

METHODS: We conducted 25 semi-structured interviews between April and October 2013 with patients who had had at least two visits with their PCP in the 6 months prior to recruitment into the study, and had requested a same-day appointment in the year prior. Interviews were audio-recorded and transcribed. Data were analyzed inductively using grounded theory techniques.

RESULTS: Patient assumptions about whether they could gain same-day access to their PCP (or to PC in general) affected whether they sought care from PC or directly from the site's urgent care center. Many patients preferred to see a provider in PC if they thought they could get an appointment. Assumptions about access to PC were based largely on prior experiences, including previous success in obtaining same-day PC access, the perception that their provider was "booked up," experience with a part-time provider who was often unavailable, and experiences with PC clinic processes that necessitated long lead-times to get a routine appointment. Most patients preferred to see their own PCP for acute issues related to a chronic condition, but were willing to see any PCP for unrelated acute issues. Further, patients were willing to see alternate PCPs if they thought that their electronic medical record gave these PCPs adequate information, or if they accepted that their part-time PCP was often unavailable. Some patients were willing to use alternate modes of access such as a telephone visit or secure electronic communication with their PCP, or a visit with the nurse on their team.

CONCLUSIONS: Previous experiences with the PC clinic is a main driver of where patients choose to seek care for urgent issues, and current patterns of care-seeking may not reflect patient preferences in some cases. As clinics make significant changes in access, it will be important to educate patients about the availability of PC appointments, and new ways to get care (e.g., through non face-to-face care or with their team nurse). Clinics will want to move toward aligning triage processes with patient preferences. In constructing access and continuity metrics that allow clinics to meet the needs of patients, policy-makers should consider measuring performance at a team, rather than an individual PCP level, and including modes of care other than face-to-face visits with PCPs.

PATIENT OUTCOMES AFTER GRADUATION OF RESIDENT PRIMARY CARE PHYSICIANS: DOES ACUTE CARE UTILIZATION INCREASE?

Sonja Solomon¹; Holly Gooding^{2,3}; Harry Reyes Nieva²; Jeffrey A. Linder². ¹Brigham and Women's Hospital, Boston, MA; ²Brigham and Women's Hospital, Boston, MA; ³Boston Children's Hospital, Boston, MA. (Tracking ID #1937542)

BACKGROUND: When residents graduate, their primary care patients are at risk for fragmentation of care, and may be at increased risk of adverse health outcomes and acute care utilization.

METHODS: We examined patients cared for in our hospital-based teaching practice by residents who graduated in 2010, 2011, and 2012. A patient was defined as belonging to a resident's primary care panel if the patient had seen the resident two or more times in the previous 2 years and had seen that resident more than any other provider in the clinic during that interval. For each year, we identified a transitioning patient cohort, whose residents were graduating, and a non-transitioning patient cohort, whose residents were not graduating. We measured clinic visits, emergency department (ED) visits, and hospitalizations in the 4 months before and after resident graduation. We calculated incident rates and used multivariable negative binomial regression to model the risk of clinic visits, emergency department visits, and hospitalizations by patient transition, adjusting for patient factors, resident factors, and clustering.

RESULTS: Our study population included 90 residents and 4018 unique patients who made up 5988 resident-patient pairs that transitioned ($n=3136$) or did not transition ($n=2852$) between 2010 and 2012. Patients had a mean age of 50 years old;

were 67 % women; 43 % Black, 26 % Latino, and 24 % Non-Latino White; and 78 % spoke English and 13 % spoke Spanish. The clinic visit rate for transitioning patients was 129 per 100 patients in the 4 months before transition and 102 per 100 patients in the 4 months after transition; for non-transitioning patients, the clinic visit rate was 119 per 100 patients and 94 per 100 patients for the same time periods (difference-in-differences, $p=0.13$). For transitioning patients, the ED visit rate was 29 per 100 patients before transition and 26 per 100 patients after transition; for non-transitioning patients, the ED visits rate was 28 per 100 patients and 25 per 100 patients for the same time periods ($p=0.49$). For transitioning patients, the hospitalization rate was 14 per 100 patients before transition and 13 per 100 patients after transition; for non-transitioning patients, the hospitalization rate was 15 per 100 patients and 12 per 100 patients for the same time periods ($p=0.20$). In multivariable modeling there was no increased risk for transitioning patients for clinic visits (adjusted rate ratio [aRR], 1.03; 95 % confidence interval [CI], 0.97 to 1.10), ED visits (aRR, 1.05; 95 % CI, 0.92 to 1.20), or hospitalizations (aRR, 1.04; 95 % CI, 0.83 to 1.31).

CONCLUSIONS: Acute care utilization and clinic visits did not increase or decrease in the 4 months after graduation of resident physicians. However we observed a high rate of acute care utilization in all time periods examined. Residents care for a population at high risk of acute care utilization, and interventions to improve ambulatory continuity of care should be employed throughout the academic year.

PATIENT PERCEPTIONS OF INTENTIONAL MEDICATION DISCONTINUATION Amy Linsky^{1,2}; Steven R. Simon^{1,3}; Barbara G. Bokhour^{4,5}. ¹VA Boston Healthcare System, Boston, MA; ²Boston University School of Medicine, Boston, MA; ³Brigham and Women's Hospital, Boston, MA; ⁴ENRM Veterans Affairs Medical Center, Bedford, MA; ⁵Boston University School of Public Health, Boston, MA. (Tracking ID #1938173)

BACKGROUND: Adverse outcomes from inappropriate medication use, whether measured as adverse clinical events, increased health care costs or decreased quality of life, are pervasive, even within an integrated health care system such as the Veterans Health Administration (VA). While medication adherence and medication reconciliation receive considerable attention, there has been less focus on improving intentional, proactive discontinuation of medications that may no longer be necessary or whose benefits no longer outweigh associated risks. Although discontinuation is often a provider decision, patient perspectives of such discontinuation are important to understand. Therefore, our objective was to identify patient beliefs and attitudes associated with intentional medication discontinuation.

METHODS: We conducted 30–60 min semi-structured qualitative interviews with 20 Veterans and two 60–90 min focus groups with another 7 Veterans. All patients received Primary Care at a VA Medical Center and were taking five or more medications. Patients were asked about their experiences with and attitudes toward taking multiple medications, preferences about taking fewer medications, communication with their clinical providers about medications, and actual or hypothetical response to their provider suggesting to stop a medicine. Fully transcribed interviews were analyzed based on the principles of grounded theory, including open coding, theme development and constant comparative analysis of cases.

RESULTS: The study participants (22 male, 5 female; 22 white, 5 black) had varying exposure to care within the VA and care in non-VA settings. We identified five domains related to Veterans' perceptions of medication taking and potential discontinuation. 1) Knowledge - Understanding medications' indications, as well as whether they provided symptom relief, influenced patients' interest in continuing medication regimens. 2) Internal conflict - Nearly all Veterans expressed their preference not to take any medications, yet because they were recommended for their health, they continued to "follow doctors' orders." 3) Communication - Many patients were selective in the information they shared with their providers. Concomitantly, there was a general interest in receiving a rationale from providers when given a recommendation to cease taking a medication. 4) Experience with medication discontinuation - Few Veterans recalled instances of proactive medication discontinuation. 5) Multiple care providers- Many patients had care from multiple providers, leading to differences in which provider's recommendations to accept, as well as the factors influencing that decision. Overall, Veterans seemed generally interested in taking fewer medications, yet did not voluntarily share these preferences with their providers. Rather, they assumed that the clinician was prescribing what is necessary for their health and did not feel they were in a position to question the provider's opinion.

CONCLUSIONS: Veterans express a variety of opinions related to medication taking and potential medication discontinuation. For those patients who have a preference to take fewer medicines but do not share their beliefs with providers, there is opportunity to improve the engagement of patients as active players in their health

care and enhance communication between patients and providers. Further, while others have noted that providers may believe a patient will feel abandoned by discontinuation of a medication therapy, our findings demonstrate that many patients would welcome such a reduction in pill burden. Future investigation into the full range of patient beliefs will enable development and implementation of targeted interventions that eliminate overuse of potentially inappropriate medications.

PATIENT PREFERENCES FOR CONSENT FOR SECONDARY USES OF ELECTRONIC HEALTH INFORMATION David Grande^{1,2}; Nandita Mitra^{3,2}; Fei Wan³; Anand Shah^{4,5}; David A. Asch^{1,6}. ¹University of Pennsylvania, Philadelphia, PA; ²University of Pennsylvania, Philadelphia, PA; ³University of Pennsylvania, Philadelphia, PA; ⁴UT Southwestern Medical Center, Dallas, TX; ⁵PCCI, Dallas, TX; ⁶Philadelphia VA Medical Center, Philadelphia, PA. (*Tracking ID #1938322*)

BACKGROUND: The widespread adoption of EHR systems has markedly increased the availability of patient-level electronic health information. This information has substantial value across a range of uses from biomedical research to commercial marketing leading to debate around the role patient consent should play. The federal government has proposed new regulations that would relax requirements for consent for information-based research that poses minimal risk. Because consent for information use has been central to current policies on data use, but new proposals subordinate the role of consent, we examined public perceptions of the importance of consent for health information use.

METHODS: We performed a national experimental survey of 3,064 people (reflecting a 65 % response rate) from a nationally representative panel (GfK Knowledge Networks), structured as a randomized controlled trial, to examine perceptions of different uses of electronic health information under different consent arrangements. We randomized individuals to 2 of 8 vignettes describing the use of electronic health information reflecting the rate and predictors of use of a pharmacologic treatment. The 8 vignettes were identical except, in a $2 \times 2 \times 2$ design, they systematically varied along three dimensions: patient consent (obtained vs. not obtained), use (research vs. commercial marketing), and the framing of how the findings would be or were used (abstract vs. specific benefits). Participants rated the appropriateness of each vignette on a 1–10 scale (1 = not at all appropriate; 10 = very appropriate).

RESULTS: Mean participant ratings ranged from a low of 3.90 for the scenario describing a marketing use when consent was not obtained and the framing was a past and specific use to a high of 6.95 for the scenario describing a research use when consent was obtained and the framing was a past and specific use. Participants rated scenarios where consent was obtained as more appropriate compared to scenarios where consent was not obtained (+1.02; $P < 0.001$). Participants rated scenarios where the use was marketing as less appropriate compared to when the use was research (-1.88 ; $P < 0.001$). Participants rated the scenarios with different framing equally (-0.03 ; $P = 0.86$ for future abstract benefits vs. past specific benefits). Overall, the effect of use was greater than the effect of consent on participants' ratings of appropriateness (1.88 vs. 1.02; $P < 0.001$). Minority respondents rated the consent arrangements similarly (consent* African American interaction: -0.19 , $P = 0.54$; consent*Hispanic interaction: 0.10 , $P = 0.73$).

CONCLUSIONS: As more electronic health information is available, the potential uses will grow. Clear policies are needed to guide stewardship of information. Our study shows that although the effects of both consent and use were measurable, use was a more important factor than whether consent was obtained. Respondents preferred the use of personal health information for research purposes even without consent over its use for marketing purposes even with consent. These views about research uses and consent policies were consistent regardless of race and ethnicity. Our study suggests we may need to focus more attention on the social value of information use and perhaps apply different standards of consent across uses. Such an approach contrasts with current policies where research uses of this information are often subjected to the strictest standards of consent.

PATIENT SAFETY IMPLICATIONS OF SHARED VISIT NOTES: TRAINEE AND PRECEPTOR VIEWS Bradley Crotty^{2,1}; Sigall K. Bell¹; Melissa Anselmo¹; Lydia A. Flier¹; Suzanne Leveille¹; Roanne Mejilla¹; Jan Walker¹. ¹Beth Israel Deaconess Medical Center, Boston, MA; ²Beth Israel Deaconess Medical Center, Boston, MA. (*Tracking ID #1940605*)

BACKGROUND: Safety experts seek ways to reduce medical errors in ambulatory care. OpenNotes, an innovation that invites patients to see their doctors' notes online, may promote patient safety through increased transparency, but may also "expose"

errors previously unseen by patients. We explored trainee and preceptor perceptions about errors in trainee notes and the anticipated effects of shared visit notes on patient safety.

METHODS: Three focus groups with trainees and preceptors from various departments discussing: anticipated effects of shared notes on safety, clinician concerns, anticipated patient reactions to errors, and suggestions). Sessions were recorded and professionally transcribed. We analyzed transcripts using established qualitative methods.

RESULTS: Focus group participants generally agreed that shared notes may improve patient safety, through: 1) increased medication and health maintenance adherence; 2) familiarity with facts, allergies, and review of visits/instructions; and 3) opportunity for patients to catch mistakes and update family history. Some specialists worried that shared notes may harm some patients, and lead doctors to document less, restricting MD-MD communication ("I want to make sure I can communicate this to the referring physician without sugar-coating it.") Trainees wrestled with what constitutes an error, which mistakes would bother patients (wrong side/gender documentation, wrong diagnosis, misquoting), and "who holds the truth" when patients and doctors disagree. Most believed patients would appreciate transparency, and welcomed corrections that prevented chart propagation of mistakes; others worried patients may lose faith in their doctors. Some added "too much honesty" (like a suspected wrong sponge count) could "freak someone out." A few had anxiety about medical-legal risk, and thought patients might "scour" the notes. Trainees needed help responding to errors. They advocated education, enhanced professional dictation proofing, note disclaimers (re: dictation errors), preceptor feedback, triage support for patient calls, and enhanced editing capability instead of note addenda to fix mistakes. Preceptors struggled with tensions between supervision, time pressure, and educational goals—conceding that they, (and trainees), may just sign notes to keep up. Some were particularly concerned about liability: "Open sesame, look what they wrote." Preceptors underscored increased vigilance to catch errors, and system fixes requiring a cosignature before trainee notes are available to patients.

CONCLUSIONS: Trainees and preceptors generally agree that shared notes have the potential to improve patient safety. Trainees worried about patients finding trivial and real errors in their notes, (and how to handle these), signaling the need for education and support systems. Preceptors were most concerned about liability and time/system constraints for adequate oversight and teaching. Note transparency may expose safety vulnerabilities and errors otherwise unseen, providing opportunities to engage patients in safety, address workload constraints, enhance trainee feedback, and reinforce culture of safety principles.

PATIENT-CENTERED MEDICAL HOME IMPLEMENTATION AND PROVIDER JOB TURNOVER Philip W. Sylling¹; Edwin Wong^{1,4}; Chuan-Fen Liu^{1,4}; Susan Hernandez^{1,4}; Adam Batten¹; Christian Helfrich^{1,4}; Karin M. Nelson^{1,2}; Stephan D. Fihn^{3,5}; Paul Hebert^{1,4}. ¹VA Puget Sound Healthcare System, Seattle, WA; ²VA Puget Sound Healthcare System, Seattle, WA; ³University of Washington, Seattle, WA; ⁴University of Washington, Seattle, WA; ⁵Veterans Health Administration, Seattle, WA. (*Tracking ID #1938371*)

BACKGROUND: The aim of this study was to examine the relationship between the implementation of a patient-centered medical home (PCMH) model and primary care provider (PCP) job turnover. The Veterans Health Administration (VHA) began implementing a PCMH through its Patient Aligned Care Team (PACT) initiative in April 2010. Although elements of PACT have been individually associated with greater PCP job satisfaction, the magnitude of organizational change required by PACT's restructuring of primary care may result in higher provider turnover, at least in the short-term. Existing literature has not specifically examined the effect of PCMH on PCP turnover.

METHODS: We applied an interrupted time series model using VHA administrative data. PCP turnover was defined by providers' dropping out of the primary care workforce for two or more consecutive quarters. We constructed discrete-time longitudinal data from PCPs employed by the VHA anytime from 2003 to 2012 with the unit of analysis at the PCP-quarter level. PCPs included physicians, nurse practitioners, and physician assistants. We estimated the association between PACT and provider turnover using logistic regression and adjusted for seasonality and secular trend, provider and job characteristics, and the local area unemployment rate. For adjusted analysis, we calculated average marginal effects (AMEs), which reflected the change in PCP turnover probability associated with unit increases in the explanatory variables. To examine differential effects of PACT across providers, we interacted a PACT indicator variable with PCP demographics.

RESULTS: The unadjusted quarterly rate of PCP turnover was 3.06 % prior to PACT and 3.38 % after PACT. In adjusted analysis, PACT was associated with higher

provider turnover ($AME=0.004, p=0.004$). The association between PACT and PCP turnover was significantly different across age groups and experience levels. PACT was associated with a $-0.0008 (p=0.711)$, $0.0046 (p=0.011)$, and $0.0069 (p=0.002)$ percentage point increase in turnover probability for providers under age 45, age 45 to 55, and over age 55, respectively. Compared to PCPs with 5 years of experience ($AME=0.0019, p=0.239$), the estimated effect of PACT on turnover was higher for PCPs with 20 years of experience ($AME=0.0106, p<0.001$). Provider type was also associated with baseline provider turnover. Nurse practitioners ($AME=0.0055, p<0.001$) and physician assistants ($AME=0.0084, p<0.001$) had higher baseline turnover than physicians.

CONCLUSIONS: PCMH implementation in VHA primary care required providers to adopt a team-based model of care as well as utilize new patient-centered forms of care delivery. This transition represented substantial organizational change which may have increased job stress among some providers. Our results suggest that PCMH implementation was associated with higher initial provider job turnover, particularly among older and more experienced providers. From a policy perspective, health system decision makers should consider the potential short-term impact of increased PCP turnover when implementing PCMH models, which could adversely impact quality of patient care delivery. Also, health systems implementing PCMH may maximize resources by focusing retention efforts on older and more experienced providers.

PATIENTS WHO SHARE TRANSPARENT VISIT NOTES WITH OTHERS: CHARACTERISTICS, RISKS AND BENEFITS Sara L. Jackson¹; Roanne Mejilla²; Jonathan Darer⁵; Natalie Oster¹; James Ralston³; Suzanne Leveille⁴; Jan Walker²; Tom Delbanco²; Joann G. Elmore¹. ¹University of Washington, Seattle, WA; ²Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; ³Group Health Cooperative, Seattle, WA; ⁴University of Massachusetts, Boston, MA; ⁵Geisinger Health System, Danville, PA. (Tracking ID #1936331)

BACKGROUND: Inviting patients to read their primary care visit notes may improve communication and help them engage more actively in their health care. Little is known about how patients will use the opportunity to share their visit notes with family members or caregivers, or what the benefits might be.

METHODS: The OpenNotes study invited patients to access their primary care providers' visit notes in Massachusetts, Pennsylvania, and Washington. Pre- and post-intervention surveys assessed patient demographics, standardized measures of patient-doctor communication, sharing of visit notes with others during the study, and specific health behaviors reflecting the potential benefits and risks of offering patients easy access to their visit notes.

RESULTS: Fifty-five percent of the 4,516 participants who reported viewing at least one visit note would like the option of letting family members or friends have their own access to their visit notes, and 980 (22 %) reported sharing their visit notes with someone during the study year. Participants who shared their visit notes were more likely to report they took better care of themselves and did better with taking their medications as prescribed, after adjustment for age, gender, employment status, and study site. Men, and those retired or unable to work, were significantly more likely to share visit notes, and sharers were neither more nor less concerned about their privacy than were non-sharers.

CONCLUSIONS: One in five OpenNotes patients shared a visit note with someone, and sharers reported better adherence to self-care and medications. As health information technology systems increase patients' ability to access their medical records, facilitating access to caregivers may improve health behaviors.

PATIENTS' PERCEPTIONS OF ELECTRONIC SYSTEM MESSAGING WITH PHYSICIANS Neil J. Farber; Lisa J. Wastila; John Fontanessi. University of California, San Diego, La Jolla, CA. (Tracking ID #1913265)

BACKGROUND: Although electronic messaging has been used to improve the medical care of patients in various studies, there are concerns by physicians about the appropriate use of messaging. Concerns by physicians include the possibility of urgent medical problems not being addressed in a timely manner. There is also the concern of the inappropriate use of e-mail for sensitive issues or those requiring face-to-face communication. Recent studies assessed only those patients who have e-mailed about all issues rather than the total with medical problems. In addition, there are no prior studies assessing patient who have not yet signed on to such systems. We therefore conducted a survey of patients who signed on, and have not yet signed on, to a messaging system as to their perceptions about its use.

METHODS: A survey was developed which uses hypothetical scenarios in which patients might use electronic messaging vs. the telephone to communicate with their

physicians. The survey was validated among 20 General Internal Medicine faculty, and then pretested in 30 patients in a university faculty practice. The survey instrument asks how likely they would send an e-mail message via the electronic messaging system to their physician in 12 different scenarios. The hypothetical scenarios vary according to the urgency and seriousness of the symptoms and possible underlying diagnoses, with 2 of the scenarios deemed acceptable for patients to e-mail their physicians, and 10 deemed as unacceptable for electronic messaging to be used to communicate the problem. A total of 500 patients in a university faculty practice completed the questionnaire. The total number of correct responses to scenarios was calculated and used to compare electronic messaging users and non-users via student T tests. The total number of scenarios that were deemed as a correct response was used as an independent variable in analyses of the impact of demographic variables via multiple regression analyses.

RESULTS: Of the 500 responses, 33 had no access to e-mail of any kind and were therefore eliminated from the analysis. The respondents were largely well educated, with about 2/3 having signed up for the electronic messaging system. A large portion of respondents incorrectly used electronic messaging in the hypothetical scenarios, with 7 % and 26 % indicating they would not use electronic messaging in the two situations which were deemed appropriate for electronic messaging, and 27–59 % likely to use it in the 10 situations which were deemed inappropriate. Patients who had signed up for electronic messaging were significantly more likely to appropriately use electronic messaging than those who had not signed up for it ($p<0.001$) and female patients were more likely to correctly use electronic messaging than male patients ($p<0.001$).

CONCLUSIONS: Patients may have inaccurate perceptions of the appropriateness of using electronic messaging for relating symptoms of an urgent nature and receiving test results which should be conveyed in person. Those patients who have not signed up for electronic messaging, and therefore have not received guidelines about its use, are particularly at risk for misperceptions about using the system. All patients who use electronic messaging should be educated about its appropriate use.

PATIENTS' VS. PHYSICIANS' VIEWS ON HOSPITALIZATIONS AVOIDABLE THROUGH OUTPATIENT MANAGEMENT Sang Been N. Hong; Nirav Vakharia; James Pile; Erik Howell; Kristen Boyer; Kelly Nottingham; Jacqueline Fox; Neha R. Pidatala; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Tracking ID #1940155)

BACKGROUND: There is increasing pressure and incentive for hospitals to reduce avoidable admissions. One potential way to reduce admissions is through better outpatient management. Understanding the patient perspective on what is preventable is important for developing successful outpatient management strategies. However, patients' views on the nature of their admissions are poorly described.

METHODS: We reviewed 322 serial admissions to a general medicine service at an academic medical center in December 2013. For each admission, the attending physician was asked to determine whether the admission was preventable, defined as the presence of any factor during the 2 weeks prior to admission which, if addressed in the outpatient setting, could have prevented the hospitalization. For each admission deemed preventable, the physician selected one primary and any number of secondary factors that led to the hospitalization from a pre-formed list (including an "other" option). The list was categorized into system, clinician, and patient factors. Every sixth patient with a preventable admission was approached for an open-ended interview. If the patient was unavailable, the next available patient was chosen for interview. Patients unavailable for interview included those who were discharged, confused, or impaired and unable to communicate appropriately. Patients were asked to identify any actions that might have been taken by the patient or outpatient physician in the 2 weeks prior to admission to prevent the current hospitalization, and to identify any barriers to those actions.

RESULTS: Of 122 admissions deemed preventable by an inpatient attending physician, 39 patients were approached for interview, and a total of 20 patients (16 %) were interviewed. Overall, patients were less likely than physicians to identify their admissions as preventable (30 % vs 100 %, $p<0.01$). Physicians attributed 50 % of admissions primarily to patient factors, 25 % to system factors, and 25 % to clinician factors. In contrast, patients were equally as likely to identify patient factors (10 %) as they were system and clinician factors (10 % each) as primary contributing factors to hospitalization. Of 12 patients (60 %) who were identified by physicians as having a patient factor contributing in some way—primarily or secondarily—to the admission, none identified the same primary contributing factor as the physician. Patient factors commonly identified by the physicians were secondary gain (42 %), non-adherence (42 %), unreasonable expectations or demands (33 %), and mental health or substance abuse (25 %). In contrast, patients primarily attributed their

admissions to a fear of hospitals and doctors that prevented timely access to care, inappropriate inpatient management at an outside hospital, and inadequate pain management by the health system—none of which were factors recognized by the physicians. In only one case did the patient and physician identify the same factor—homelessness—as contributing to the admission. Similarly, of 12 patients (60 %) identified by physicians as having system or clinician factors that led to admission in some way, only one identified the same primary factor—an unaddressed problem from the last admission—as did the physician.

CONCLUSIONS: Patients frequently disagree with physicians as to whether their admissions are preventable through better outpatient management. Disagreement may be most pronounced regarding those things deemed by the physician to be within the patient's control. This patient perspective will need to be considered when devising interventions to reduce preventable admissions. Further studies of patients' understanding of the roles of inpatient care, outpatient care, and patient responsibility are needed to inform patient education efforts.

PATTERNS AND PREDICTORS OF MEDICATION DISCREPANCIES IN PRIMARY CARE Daniel J. Coletti^{1,2}; Hara Stephanou²; Nissa Mazzola³; JoAnne Gottridge²; Joseph Conigliaro²; John M. Kane¹. ¹The Zucker Hillside Hospital, Glen Oaks, NY; ²North Shore-Long Island Jewish Health System, Great Neck, NY; ³St. John's University, Jamaica, NY. (*Tracking ID #1929866*)

BACKGROUND: It has been estimated that having patients take a correctly prescribed medication, as prescribed, would result in a savings of \$290 billion in avoidable medical costs (constituting 13 % of US healthcare expenditures). Extensive research has documented the impact of patient adherence on medication regimens as well as pervasive problems establishing and maintaining accurate and effective patient medication lists across time and settings of care. Research examining the relations between medication discrepancies and patient adherence to treatment, however, is limited. The primary objective of this investigation was to explore relationships between patient-reported adherence and the presence of patient-provider medication discrepancies in primary care. We sought to examine relations between medication discrepancies, attitudes to health and medication, and perceived physical and emotional well being. We also tested the hypothesis that patient-reported non-adherence would be associated with the presence of medication discrepancies.

METHODS: Eligible participants were enrolled patients in a large, hospital-affiliated patient-centered medical home serving a socioeconomically and culturally diverse catchment area. Participants completed several questionnaires assessing attitudes to health, treatment adherence, emotional and physical functioning, patient activation, and health literacy. Medication discrepancies were examined by comparing each patient's self-reported medication list for the previous week to all active medications recorded in the patient's electronic health record at the time of their visit. Discrepancies were categorized as involving a) over-the counter medications and/or supplements, b) time-limited prescriptions, c) medications prescribed to be taken as needed (PRN), d) topic/external agents, and e) an active, daily prescription medication treatment. Electronic record review was conducted by two trained raters using a standardized review algorithm. Multivariate logistic regression was used to identify variables associated with an active medication treatment discrepancy.

RESULTS: A total of 328 patient-participants (217 women and 111 men, mean age = 49.23 years, SD=15) were taking one or more medications and had a subsequent medical encounter during which medication reconciliation practices could be examined. Participants' self-assessment of their medication regimens suggested relatively high rates of adherence, with the obtained ASK-12 mean score of 23.69 (SD=7.22) indicating fewer adherence barriers than the mean of 27.5 (SD=7.20) obtained in a published validation sample ($t=9.69$, $df=323$, $p <.001$). However, a significant difference was obtained between number of medications reported by patients ($M=3.79$, $SD=3.13$) and the number of active medications in the medical record ($M=4.83$, $SD=3.96$, $t=6.62$, $df=327$, $p <.001$). At least one discrepancy was identified in most patient records (294/328 or 89.6 %). Full or partial medication reconciliation during the medical encounter occurred in only 62/294 (21.1 %) of patients with discrepancies. Additional analyses were completed on a subgroup of 189 patients with one or more discrepancies involving an active, daily, prescribed medication treatment. The presence of one or more daily prescribed treatment discrepancies was associated with lower levels of health literacy, lower subjective well being and patient activation, higher levels of functional impairment, and poorer adherence to the regimen patients believed they had been prescribed. Multivariate analysis, however, indicated that the most significant predictors of medication discrepancies were the number of medication orders in the patient's medical record, and subjective well being.

CONCLUSIONS: Results from this investigation indicate significant rates of non-concordance between patient representations of their medication regimens and their primary care medical record. Working towards patient-provider agreement on the desired medication regimen, therefore, is likely to be a necessary first step before making valid attempts to address patient adherence. Findings suggest a positive relation between patient non-adherence and the presence of patient-medical record discrepancies. Multivariate results, however, suggest that closing these gaps might best be accomplished by addressing patients' emotional state as well as making attempts to simplify medication regimens when possible. Observed associations between medication discrepancies and multiple cognitive, functional, emotional, and behavioral patient variables suggests that medication review and reconciliation interventions should combine information about medication with behavioral, emotional, and problem solving supports to help patients understand, coordinate, maintain, and adhere to their medication regimen.

PAYMENT REFORM IN MASSACHUSETTS: EFFECT OF GLOBAL PAYMENT ON HEALTH CARE SPENDING AND QUALITY 4 YEARS INTO THE ALTERNATIVE QUALITY CONTRACT Zirui Song^{1,2}; Dana G. Safran^{3,4}; Bruce E. Landon^{1,5}; Sherri Rose¹; Matthew Day³; Michael E. Chernew^{1,2}. ¹Harvard Medical School, Boston, MA; ²National Bureau of Economic Research, Cambridge, MA; ³Blue Cross Blue Shield of Massachusetts, Boston, MA; ⁴Tufts University School of Medicine, Boston, MA; ⁵Beth Israel Deaconess Medical Center, Boston, MA. (*Tracking ID #1939467*)

BACKGROUND: Slowing the growth of health care spending while improving quality of care remains a national priority. Global payment within accountable care organizations has received increasing attention as a potential way to control spending while improving quality. In 2009, Massachusetts began moving away from fee-for-service with the Blue Cross Blue Shield of Massachusetts Alternative Quality Contract (AQC). The AQC pays provider organizations a global budget that covers the entire continuum of care, while rewarding up to 10 % of the budget in additional quality bonuses. In the ensuing years, membership in the AQC has grown. We evaluated the effect of the AQC on spending and quality after 4 years.

METHODS: We used claims and quality data in a difference-in-differences design to assess the association between the AQC and changes in spending and quality. For the 2009 AQC cohort, the pre-intervention period was 2006–2008, while the post-intervention period was 2009–2012. In addition to basic unadjusted analysis, we used propensity-weighted linear regression models at the enrollee level adjusting for demographics, health status, secular trends, and plan benefit design. We conducted a number of sensitivity analyses, consistent with our prior work. We decomposed the AQC effect by year, as well as by type of care, site of care, health status, risk contracting experience, and price versus utilization effects.

RESULTS: The 2009 AQC cohort comprised about 500,000 unique enrollees across the study period whose primary care physicians belonged to organizations that entered the AQC in 2009. Building on prior work demonstrating AQC-associated savings of 1.9 % in year-1 and 3.3 % in year-2, preliminary analyses show that the AQC continued to slow medical spending in years 3 and 4, on average exceeding 5 % in these years. Medical savings were larger than the sum of budget surpluses and quality payments. Accounting for shared savings and quality bonuses, total health care spending growth after 4 years was lower than the targeted state economic growth of 3.6 %. Savings were larger among organizations without prior risk contracting experience. Changes in both prices (through referral pattern changes) and volume helped explain the results, which were evident in imaging, tests, and procedures. Achievement of quality in chronic care management improved from 79 % in 2007 to 86 % in 2012; adult preventive care from 74 to 82 %, and pediatric care from 79 to 85 %. Analogous results for subsequent cohorts were broadly consistent.

CONCLUSIONS: After 4 years, the AQC was associated with a slowing of spending growth and improved quality. Combining global budgets with pay-for-performance for accountable care organizations may be a successful model for slowing spending and improving quality. Global payment may be able to encourage greater price competition without threatening quality. The AQC could be informative for Medicare in both its Shared Savings and Pioneer ACO programs, as well as for other commercial insurers across the country engaged in payment reform.

PEER SUPPORT FOR CHRONIC PAIN SELF-MANAGEMENT: A QUALITATIVE STUDY OF PEER COACHES' EXPERIENCES Marianne S. Matthias; Marina Kukla; Alan B. McGuire; Matthew J. Bair. Roudebush VAMC, Indianapolis, IN. (*Tracking ID #1937546*)

BACKGROUND: Chronic pain is prevalent, disabling, and costly. Pain reduces quality of life and is associated with emotional distress when it interferes with work, social and recreational activities, and family life. In this study we elicited the experiences of peer coaches who participated in an intervention to support patients' chronic pain self-management.

METHODS: The intervention lasted 4 months. Ten peer coaches with chronic musculoskeletal pain who had participated in a prior pain self-management study participated. Peer coaches attended a 3-hour group training session, which included instruction on goal-setting, motivational interviewing, and role playing. Coaches participated in regular supervision calls with the study psychologist during the intervention, which reinforced training, taught additional motivational strategies, and provided a forum to discuss questions or concerns. Each coach was assigned two patients with musculoskeletal pain, matched, to the extent possible, on age and pain location. Pairs were asked to meet or talk via telephone at least biweekly for 4 months, guided by a study manual on pain self-management. Coaches were asked to discuss different topics in the manual at each meeting, while also providing encouragement, support, and motivation. After the intervention, coaches and patients were asked open-ended questions about their experiences with the intervention. Interviews were audio-taped, transcribed, and checked for accuracy. We used constant comparative methods to analyze the data.

RESULTS: Nine peer coaches completed the study; ages ranged from 50 to 71 ($M=60$, $SD=7$) years. All were male veterans. Although the intervention targeted patients, peer coaches described benefitting from the study in three key ways: 1) establishing an interpersonal connection with other veterans with pain, 2) putting their own problems in perspective, and 3) strengthening their own pain self-management practices. Each theme is described below. Theme 1: Interpersonal Connections. Coaches valued the human connection they made with another person: "Getting to know them...their private life, situation... the interpersonal contact... that's fun, rewarding" (P106). Another coach echoed these sentiments: "The most important part was the opportunity to engage someone else... we learn about each other and...I profit from that, too." (P112) Theme 2: Putting Problems into Perspective. For some peer coaches, participating in the intervention made them realize their own problems were relatively small. One coach stated, "You think you've got...problems, and then you talk to somebody that has real...problems, it sort of grounds you." (P104) For another coach, talking to his assigned patients, as well as to many of his friends, "makes me appreciate that although I have my own little problems, my problems are much smaller...I feel lucky." (P107) Theme 3: Strengthening Self-Management Practices. For many coaches, discussing pain self-management with their partners served as an important reinforcement of their own pain self-management practices. One coach described helping his patients learn stretching exercises, which he also committed to do with them. As a result, "it actually got me into a stretching routine that was good" and "strengthened my resolve and ability to deal with my own pain." (P106) Another coach noted that the intervention "showed me that I needed to work on my pain a little bit more, and maybe my attitude. You know, get motivated a little bit more." (P102)

CONCLUSIONS: Peer coaches described several benefits of participating in a peer support intervention for chronic pain self-management. Additional research is needed to better understand the benefits of peer support for both patients and peer coaches with chronic pain.

PERCEPTIONS OF INTERNAL MEDICINE RESIDENTS ON SUDDEN DISRUPTIONS TO THEIR TRAINING: A STUDY OF HURRICANE SANDY

Shaun K. Yang¹; Yixin Fang²; Patrick M. Cocks¹. ¹New York University School of Medicine, New York, NY; ²New York University School of Medicine, New York, NY. (Tracking ID #1927669)

BACKGROUND: The effect of natural disasters on medical residency training remains largely unstudied. Hurricane Sandy made landfall on October 29, 2012 and forced the subsequent evacuation and closure of the three teaching hospitals of the New York University (NYU) internal medicine residency program. To minimize the disruptive effects from the storm, NYU internal medicine residents were deployed to nearby medical centers to resume their residency training with the support of neighboring internal medicine residency programs. The objective of this study was to describe the effect of Hurricane Sandy on medical residency training based on the reported experiences of NYU internal medicine residents.

METHODS: All 148 residents of the NYU internal medicine residency program were absorbed by 13 hospitals across New York City. Residents were deployed to offsite general medicine ward rotations for three months in the form of independent

ward teams along side the host residency programs. Seven months after Hurricane Sandy, we conducted a cross-sectional survey of all NYU internal medicine residents. Residents were contacted by email and responded via an anonymous electronic survey. Respondents were asked, "What impact has Hurricane Sandy had on your clinical training?" and the 5-point scale ranged response options from "substantially positive impact" to "substantially negative impact" and included the option of "really hard to say". Respondents were asked to elaborate on their answer with a follow-up free response question. Surveys were fielded and data de-identified by a third party independent of the residency program. Free responses were categorized into common themes. Descriptive statistics were used to summarize the responses. A chi-squared analysis examined the association between the perceived impact on training and the year of residency.

RESULTS: Eighty-six residents completed the questionnaire (58 % response rate). Respondents consisted of 35 first-year residents (41 %), 30 second-year residents (35 %) and 21 third-year residents (24 %). Only five residents (6 %) reported that Hurricane Sandy had a "substantially negative impact" on their clinical training, 44 residents reported a "slightly negatively impact" (51 %), 15 residents reported "slightly positive impact" (17 %), 1 resident reported "substantially positive impact" (1 %), 10 residents reported "no real impact" (12 %), and 11 residents reported the impact of Hurricane Sandy as "really hard to say" (13 %). There was no association between the perceived impact on training and the year of residency ($p=0.251$). Frequently cited reasons among residents who reported a slightly or substantially negative impact included missed critical care rotations (26 %), fewer educational activities (19 %), lower patient volume (16 %), lower case acuity (13 %), missed general medicine floor rotations (13 %), learning a new hospital system (8 %), commuting (6 %), and credentialing (3 %). Common reasons among residents who reported a slightly or substantially positive impact included the exposure to other hospital systems and residency programs (23 %), exposure to disaster medicine (5 %), and increased time for education (5 %).

CONCLUSIONS: Natural disasters have the potential to impede the training of medical residency programs and our data suggest strategies to minimize the negative consequences by including specialized rotations and increased educational activities. Observational studies using competency-based assessments could help to determine the sustained effects of natural disasters. Finally, strategies to maintain residency programs should be considered in regional policies for disaster preparedness and response.

PERI-OPERATIVE USE OF MEDICAL CONSULTANTS AND 30-DAY MORTALITY RATES

Lena M. Chen; Adam S. Wilk; Edward C. Norton; Mousumi Banerjee; John D. Birkmeyer. University of Michigan, Ann Arbor, MI. (Tracking ID #1931367)

BACKGROUND: Use of medical consultants for surgical inpatients varies widely, but its association with mortality is unknown. Therefore, we sought to describe the association between peri-operative medical consult use and mortality.

METHODS: We conducted an observational, retrospective cohort study of fee-for-service Medicare beneficiaries 65 years of age or older, who underwent colectomy or total hip replacement (THR) from 2007 to 2010 at an acute care hospital. We fit two-stage least squares models to estimate the association between inpatient consult use and mortality, controlling for patient-level and hospital-level covariates (i.e., gender, age group, race/ethnicity, 29 Elixhauser co-morbidities, number of beds, teaching status, nurse staffing, urban location, profit status, and region). We used an instrumental variable—average consult use within a patient's hospital referral region in the prior year—to minimize confounding. Our two primary predictors were total number of inpatient consults and use of at least one inpatient consult. Our primary outcome was 30-day, all-cause, risk-adjusted mortality.

RESULTS: There was considerable variation in the use of inpatient medical consults (for colectomy, median of 5, IQR: 0 to 14; for THR, median of 2, IQR: 0 to 4). Sixty-nine percent (63 %) of colectomy (THR) patients had at least one consult. Unadjusted 30-day mortality rates were 5.7 % after colectomy and 0.4 % after THR. Use of one additional consult was associated with a 0.01 percentage point increase (or 0.02 pp increase) in mortality rates for colectomy (or THR), but this finding was not statistically significant ($p=0.71$ and $p=0.25$, respectively). Use of at least one consult was associated with a 0.6 percentage point decrease (or 0.05 pp increase) in mortality rates for colectomy (or THR); this finding too was not statistically significant ($p=0.49$ and $p=0.44$, respectively).

CONCLUSIONS: We found no association between peri-operative medical consult use, and 30-day, risk-adjusted mortality rates after hospitalization for colectomy or THR.

PERSISTENCE OF DIAGNOSTIC DELAY IN 2013: A BIBLIOMETRIC STUDY Claudia L. Campos; James L. Wofford. Wake Forest University, Winston-Salem, NC. (*Tracking ID #1934783*)

BACKGROUND: Previous studies of diagnostic delay have been few, inconsistent in methodology, and tentative in defining the amount of delay for specific diagnoses. The emerging field of diagnostic error deserves an update, as diagnostic delay should have decreased over time with more sophisticated diagnostic tools and greater awareness.

METHODS: We conducted a bibliometric search of the MEDLINE database using the free text phrase "diagnostic delay" and restricting our search to publications in year 2013. Abstract review allowed categorization of abstracts by country of origin, study type, and disease category. The degree of diagnostic delay was determined for most common diseases and with disease registries as the study population.

RESULTS: Of the 135 citations, most citations came from institutions in the USA (9) and UK (19), but 35 countries were represented in the search results. 12 % (17/135) of citations were from developing countries. Study type was not discernible from the abstract with 7 citations. Study types included case-reports or case-series (37), discussions/literature reviews (22), registries/clinical networks (17), physician interviews (2). There were 3 prospective studies with the remaining studies retrospective or cross-sectional in design. Disease categories were most often infection (25/135, 19 %), cancer (20), neurologic (15), rheumatologic (10), or vascular (8). The most common specific diagnoses were tuberculosis (13), ALS (4), endometriosis (3), oral cancer (3), ocular cancer (3) but other diagnoses were represented no more than twice among the citations. Disease registries offered the largest number of patients (mean 6564, range 100–56462), and specific duration of DD were offered in 16 of 17 studies. No studies of systematic approaches to diagnostic error were evident with this search strategy.

CONCLUSIONS: Diagnostic delay is alive and well in the medical literature. Compared with previous studies of diagnostic delay, findings from disease registries offer larger sample sizes and more confidence in defining duration of delay.

PERSPECTIVE OF THE GRADUATING MEDICAL STUDENT: THE IDEAL CURRICULUM FOR THE 4TH YEAR OF UNDERGRADUATE MEDICAL EDUCATION Mary Andrews^{2,1}; Nathalie Paolino^{2,1}; Brian Hemann^{1,2}; Lynn Byars^{1,2}; Steven Durning^{1,2}; Kent DeZee^{1,2}. ¹Uniformed Services University, Bethesda, MD; ²Walter Reed National Military Medical Center, Bethesda, MD. (*Tracking ID #1937644*)

BACKGROUND: Undergraduate medical education has undergone much reform in the past decade, but the final year has received little attention thus far. The aim of this study is to determine which experiences graduating medical students feel are the most important in designing a fourth year curriculum, as there are no large scale studies from the student's perspective.

METHODS: This is a cross-sectional survey study, conducted to assess the relative importance of possible experiences during the final year of medical school. A literature review was conducted to identify common educational activities that US medical schools offer in the final year. Using rigorous survey design methodology, a 24-item survey was developed based on this review. Twenty-one of the questions related to the value of various educational activities. Three questions assessed the percent of the final year respondents felt should be allocated to direct patient care, electives, and dedicated to the desired specialty of the student. Students rated each educational activity using a 5-point Likert scale (1 = not important at all; 5 = extremely important). All U.S. medical students graduating in 2012 with a military training obligation were eligible to participate. Students were invited to participate via email 2–3 months prior to graduation. The importance of the experiences was ranked by the mean.

RESULTS: The response rate was 40 % (376/942). The most important experiences were rotation opportunities at other institutions under consideration for residency training (mean 4.4, sd 0.8), clinical rotation opportunities in

desired specialty (mean 4.3, sd 0.8), opportunity to solidify clinical skills in preparation for internship (mean 4.2, sd 0.9) and allotted time for residency interviews (mean 4.0, sd 1.0). The least important experiences were learning business skills for running a practice after residency (mean 2.6, sd 1.2), opportunities to conduct research (mean 2.6, sd 1.1), the opportunity to conduct a rotation outside the United States (mean 2.7, sd 1.3) and expanding basic science knowledge (mean 2.7, sd 1.0). Students felt the 4th year should be 69 % (sd 20) direct patient care experience, 68 % (sd 17) electives, and 38 % (sd 17) in the student's desired specialty. The length of military commitment (4 years or less versus 5 years or more) did not meaningfully change any of the results.

CONCLUSIONS: This study seems to demonstrate that students appear to be more focused on the immediate concerns of residency selection and on solidifying clinical skills in their desired specialty, but place less importance on skills that will not be soon applied. Those designing final year curricula might use these data as a general needs assessment, in particular for anticipating the activities that will likely have student support and those that might have less student engagement.

PERSPECTIVES OF LIFESTYLE FACTORS ON SPECIALTY CHOICE IN 4TH YEAR MEDICAL STUDENTS Elexis McBee^{2,1}; Shalini Reddy³; Lynn Byars^{1,2}; Charles D. Magee^{1,2}; Jennifer R. Kogan⁵; Douglas Maurer⁴; Steven Durning^{1,2}; Kent DeZee^{1,2}. ¹Uniformed Services University, Bethesda, MD; ²Walter Reed National Military Medical Center, Bethesda, MD; ³University of Chicago Pritzker School of Medicine, Chicago, IL; ⁴Madigan Army Medical Center, Tacoma, WA; ⁵Pereiman School of Medicine at the University of Pennsylvania, Philadelphia, PA. (*Tracking ID #1938616*)

BACKGROUND: A specialty's lifestyle is known to be an important factor in specialty selection. It is unclear, however, whether 4th year students consider the lifestyle of a resident or attending in determining the factors most important to their specialty choice. The aim of this study is to determine if 4th year students weigh lifestyle factors differently based on the stage of their future career when considering a specialty.

METHODS: The authors conducted a cross sectional survey of 4th year medical students from the University of Chicago, the University of Pennsylvania and all 4th year medical students with a military service obligation in the United States during the 2011–2012 academic year. Using a five-point Likert-type scale (1 = not important at all; 5 = extremely important), respondents rated the importance of 14 lifestyle factors related to anticipated life as a resident physician versus anticipated life as an attending physician in choosing their specialty. The lifestyle factors surveyed related to the themes of schedule control, off time from work, and quality of the work life, as previously described in the literature. The mean of each lifestyle factor for anticipated life as both a resident and as an attending was calculated and compared using a paired t-test. Since multiple comparisons were made, a two-sided p-value of <0.01 was considered statistically significant. Effect size for each bivariate association was also calculated. Regression analysis controlling for type of medical school, presence of military obligation, and type of specialty choice was conducted for bivariate associations with a p-value <0.01.

RESULTS: The response rate for the questionnaire was 46 % (540/1184). For all 14 lifestyle factors, the level of importance for anticipated life as a resident was statistically different than anticipated life as an attending ($p<0.01$, paired t-test). The factors with the highest rated importance when considering anticipated lifestyle as both a resident and attending physician were 1) job satisfaction (resident mean: 4.6, attending mean: 4.7), 2) how enjoyable the work day will be (resident mean: 4.3, attending mean: 4.5) and 3) collegiality of coworkers (resident mean: 4.1, attending mean: 4.2). The effect size for each of these factors was 0.13, 0.26 and 0.17 respectively, indicating trivial to small differences between anticipated resident and attending life. The factors with the lowest rated importance were 1) working fewer hours (resident mean: 1.9; attending mean: 2.4), 2) minimizing the number of emergencies that affect the daily work schedule (resident mean: 2.2, attending mean: 2.8), and 3) frequency of overnight call (resident mean: 2.3, attending mean: 3.2). The effect size for each of these factors was 0.53, 0.65, and 0.80, respectively, indicating moderate to large differences. Regression analysis of each factor, controlling for type of specialty, military obligation, and type of medical school, did not alter the results.

CONCLUSIONS: When considering anticipated lifestyle related to choice of specialty, quality of work life was the most important consideration for 4th year

medical students, with no meaningful differences between anticipated life as a resident and attending physician. In contrast, 4th year medical students seem to place less importance on their anticipated lifestyle as a resident compared to an attending in the constructs of schedule control and off time from work. Future studies of lifestyle and specialty choice should emphasize anticipated lifestyle as an attending physician and not anticipated lifestyle as a resident, with the exception of work life.

PHYSICAL ACTIVITY AND RISK OF BLEEDING IN ELDERLY PATIENTS TAKING ANTICOAGULANTS Pascal Frey; Marie Méan; Andreas Limacher; Nicolai Rodondi; Drahomir Aujesky. Bern University Hospital, Bern, Switzerland. (Tracking ID #1937351)

BACKGROUND: Although the possibility of bleeding as a result of anticoagulant treatment may limit patients from taking part in physical activity, the association between physical activity and anticoagulation-related bleeding is uncertain.

METHODS: In a Swiss prospective multicenter cohort study of 988 in- and outpatients aged ≥ 65 years receiving anticoagulants for acute venous thromboembolism (09/2009–04/2013), we assessed patients' self-reported physical activity level (low, medium, or high) at baseline using a previously established standard question. The primary outcome was the time to a first major bleeding, defined as fatal bleeding, symptomatic bleeding in a critical site, or bleeding causing a fall in hemoglobin or leading to transfusions. The secondary outcome was the time to a first clinically relevant non-major bleeding. We examined the association between physical activity level and the time to a first bleeding using competing risk regression, accounting for death as a competing event. We adjusted for known bleeding risk factors, including age, female gender, overt pulmonary embolism, history of major bleeding, recent major surgery, cerebrovascular disease, cardiac disease, diabetes mellitus, arterial hypertension, active cancer, chronic liver disease, chronic renal disease, risk of falls, polypharmacy, anemia, low platelets, concomitant antiplatelet therapy, and periods of anticoagulation as a time-varying covariate.

RESULTS: During a mean follow-up of 22 months, patients with a low ($n=367$), moderate ($n=310$), and high ($n=311$) physical activity level had an incidence of major bleeding of 11.6, 6.3, and 3.1 events per 100 patient-years, and an incidence of clinically relevant non-major bleeding of 14.0, 10.3, and 7.7 events per 100 patient-years, respectively. Compared to a low physical activity level, a moderate (adjusted sub-hazard ratio [SHR] 0.72, 95 % confidence interval [CI] 0.45–1.13) and high physical activity level (adjusted SHR 0.40, 95 % CI 0.22–0.72) were associated with a lower risk of major bleeding. There was no association between physical activity and clinically-relevant non-major bleeding.

CONCLUSIONS: Increasing levels of physical activity are associated with a decreased risk of major bleeding in elderly patients receiving anticoagulant therapy, indicating that physical activity is safe when taking anticoagulants.

PHYSICIAN PERSPECTIVES OF INTERDISCIPLINARY CARE IN THE MANAGEMENT OF PATIENTS WITH DIABETES Nissa Mazzola^{1,2}; Daniel J. Coletti^{3,2}; Joseph Conigliaro². ¹St. John's University College of Pharmacy and Health Sciences, Queens, NY; ²North Shore University Hospital, Great Neck, NY; ³The Zucker Hillside Hospital, Glen Oaks, NY. (Tracking ID #1936039)

BACKGROUND: Evidence from controlled longitudinal trials suggests that effective management of Type 2 diabetes requires an interdisciplinary approach with close collaboration between team members. Prior research has described physician perceptions of barriers to effective diabetes management, but studies that describe physician insights regarding interdisciplinary teams are lacking. New efforts to integrate the services of a Certified Diabetes Educator (CDE) and Health Psychologist into a hospital-based patient-centered medical home (PCMH) offered an opportunity to evaluate physician attitudes toward interprofessional collaboration around diabetes management. Our primary objective was to compare attitudes toward diabetes management between the PCMH's medical staff and a second internal medicine practice site without an interdisciplinary diabetes team. We also sought to test for attitudinal differences toward interdisciplinary diabetes care between board-certified internists and Internal Medicine residents.

METHODS: Eligible participants for this IRB-approved study included attending physicians and residents practicing at one of two ambulatory care sites within a large, suburban, socioeconomically diverse academic medical center. A 19-item anonymous paper survey was developed to examine the perceived importance of different components of diabetes treatment and education, as well as physician perceptions of the referral process for accessing members of the diabetes team. We used 10-point Likert scale item responses. Practice site directors distributed the questionnaire to all

resident and attending physicians between January and March of 2013. T-tests for independent means were deployed to examine differences in mean item scores between the two practice sites, and between residents and attending physicians.

RESULTS: A total of 90 physicians completed the survey (25 attending physicians and 65 residents; 54 at the larger PCMH and 36 at the second IM practice site). Physicians from both sites endorsed positive attitudes to referring patients for additional education when initiating insulin therapy ($M=9.17$ out of 10 and $M=9.64$ out of 10, respectively). Respondents at both sites were significantly less confident, however, that they understood the specific roles and activities of the CDE ($M=5.8/10$ and $5.36/10$, respectively). Physicians practicing in the PCMH site perceived fewer barriers to referring their patients for diabetes education ($t=4.83$, $df=84$, $p<.001$) and were more likely to feel that their patients were seen for adjunctive services in a timely manner ($t=3.88$, $df=85$, $p<.001$). Providers in the PCMH site were more inclined to endorse the facilitation of behavior change as a component of diabetes self management education than the comparison site ($t=2.27$, $df=84$, $p<.05$). Analysis of attending-resident patterns of response suggested that residents were more likely to be influenced by concerns about consistent patient adherence than attendings in making a recommendation for insulin therapy ($t=2.01$, $df=87$, $p<.05$).

CONCLUSIONS: Results suggest that the diabetes support professionals are seen as valuable team members, and physicians are interested in learning more about their specific roles and activities. The integration of non-physician team members into the PCMH is associated with more positive attitudes around access and efficiency. The finding that residents were more influenced by concerns about patient adherence in recommending insulin therapy than attendings suggests that experience and training may lead to more confidence supporting patients in initiation of insulin. Alternatively, this finding might be related to different barriers to adherence among patients treated by attending physicians vs. patients seen by residents and warrants further investigation. Study findings are limited by the relatively small sample size, obtained within a single health system. Although the anonymous nature of the survey may have facilitated more honest sharing of perceptions about treatment and team services, it also limited the ability to inquire into more detailed information about the respondents. Our findings, however, support the feasibility of integrating diabetes support team services, the acceptability of diabetes-related behavioral interventions within a PCMH, and increased efforts at supporting resident physicians in facilitating patient adherence.

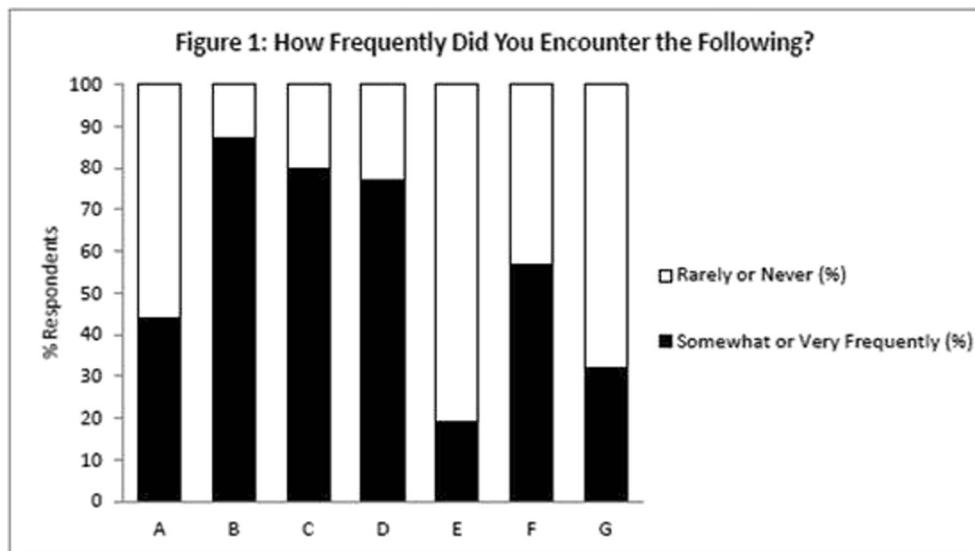

PHYSICIAN PERSPECTIVES ON INTER-HOSPITAL TRANSFERS Stephanie Mueller; Jeffrey L. Schnipper. Brigham and Women, Boston, MA. (Tracking ID #1937827)

BACKGROUND: The transfer of patients between acute care hospitals (inter-hospital transfer, IHT) is becoming increasingly common. However, lack of evidence-based guidelines to direct high quality patient transfer creates variability in the quality of the transfer process, potentially leading to poor patient outcomes. Therefore, a better understanding of problematic aspects of the transfer process from frontline providers is a crucial first step to inform development of interventions to improve the quality of IHT.

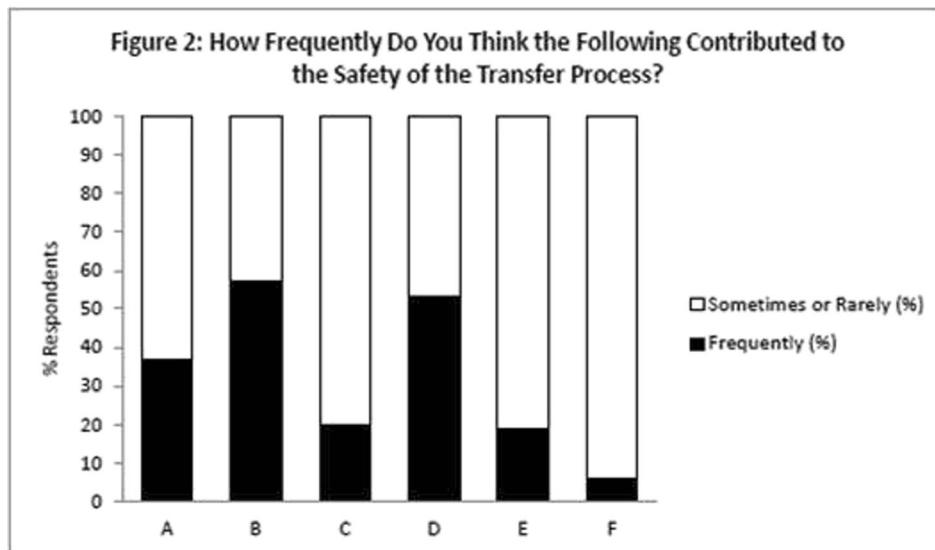

METHODS: We surveyed residents and inpatient attendings from Internal Medicine, Neurology, and Surgery at a large urban tertiary referral hospital who are involved in accepting and caring for transferred patients. Subjects were asked about the frequency with which they encountered various issues related to quality in caring for transferred patients, and whether they felt these scenarios affected the safety of the transfer process, using 5- and 3-point likert scales respectively. Responses were then dichotomized into "sometimes or frequently" vs. "rarely or never".

RESULTS: Overall response rate was 51 % (145/284) with highest response rates from Internal Medicine and Neurology residents and attendings. Responses to survey questions are shown in Figures 1 and 2. The majority of survey respondents reported that they frequently encountered transferred patients arriving without necessary transfer records, greater than 24 h after being accepted, with unrealistic expectations of care, and not requiring specialized care. In addition, survey respondents identified availability of transfer records and time of day of patient arrival as frequently contributing to the safety of the transfer process.

CONCLUSIONS: This survey identifies quality and safety issues frequently encountered by frontline providers involved in the receiving end of the transfer process, providing potential targets for improvement of the IHT process. Further research is needed to identify quality and safety issues from transferring institutions, patients' and families' perspectives, and associations with patient outcomes.

- A: Patient arrives unstable
- B: Patient arrives without necessary transfer records
- C: Patient arrives more than 24 hours after being accepted for transfer
- D: Patient/family has unrealistic expectations of available care/treatment options following transfer
- E: Patient does not require hospitalization
- F: Patient does not require specialized hospital care at your hospital
- G: Patient should have been transferred to a different service

- A: Stability of patient on arrival
- B: Availability of necessary transfer records
- C: Time delay between acceptance and arrival of patient
- D: Time of day of arrival
- E: Busyness of service/unit at time of patient arrival
- F: Appropriateness of receiving service

PHYSICIAN REPORTED USE OF STRATEGIES TO IMPROVE ADULT IMMUNIZATION Laura Hurley^{1,2}; Megan C. Lindley⁴; Mandy Allison^{1,5}; Lori A. Crane^{1,6}; Michaela Brtnikova¹; Brenda Beaty^{1,3}; Megan Snow¹; Carolyn Bridges⁴; Allison Kempe^{1,5}. ¹Children's Hospital Colorado, Aurora, CO; ²Denver Health,

Denver, CO; ³University of Colorado Anschutz Medical Campus, Aurora, CO; ⁴Centers for Disease Control and Prevention, Atlanta, GA; ⁵University of Colorado Anschutz Medical Campus, Aurora, CO; ⁶Colorado School of Public Health, University of Colorado, Denver, CO. (*Tracking ID #1926742*)

BACKGROUND: Adult immunization rates are low nationally. Several strategies have been shown to increase immunization rates, but little is known regarding their use by physicians who serve adults. In 2013, the National Vaccine Advisory Committee approved standards for adult immunization practices that included incorporating immunization needs assessment into every visit and documenting vaccinations in immunization information systems (IIS). Our objectives were to assess among general internists (GIM) and family physicians (FM): 1) practices regarding assessing immunization status; 2) strategies used to improve immunization rates and 3) factors that interfere with and characteristics associated with assessing immunization status at every visit.

METHODS: We administered an Internet and mail survey from June to October 2013 to a national network of 438 GIM and 401 FM physicians representative of the American College of Physicians and American Academy of Family Physicians memberships. In addition to descriptive analysis, we performed multivariable logistic modeling for the specialties combined to examine associations between assessing immunization status at each visit and demographic and practice characteristics and strategies used to improve adult immunization.

RESULTS: Response rates were 72 % (317/438) for GIM and 59 % (236/401) for FM. Thirty-nine percent of GIM and 42 % of FM reported assessing vaccination status at every visit. The top 2 factors that interfere “a great deal” with assessment at each visit were acute problems taking precedence over vaccinations (GIM-37 %, FM-32 %), and not having an electronic questionnaire for patients to help determine immunization status (GIM-17 %, FM-19 %). The table shows GIM and FM physicians’ practices regarding strategies used to improve vaccination rates. Characteristics associated with assessing immunization status at every visit included working at a community/hospital based clinic (OR-1.88, 95 % CI 1.26–2.78), using standing orders for at least for some ACIP recommended vaccines (OR 1.87, 95 % CI 1.26–2.78), and having an electronic clinical decision support system (CDSS) to help determine vaccine needs (OR 1.83, 95%CI 1.23–2.72).

CONCLUSIONS: Most physicians serving adults are not assessing immunization needs at each visit and cite competing demands predominately interfering with this practice. Physicians reported limited use of strategies that have been shown to improve immunization. Incorporation of these strategies could increase the likelihood of assessment of immunization status at each visit and thereby result in higher vaccination rates.

Reported Strategies Used to Improve Vaccination	GIM (%)	FM (%)
Standing orders		
Seasonal influenza*	64	83
All other vaccines*	7	15
Assessment and feedback

PHYSICIAN VISITS AND SURVEILLANCE TESTING AMONG BREAST CANCER SURVIVORS IN TAIWAN Yong A. Wang^{1,2}; An-Chen Feng²; Patricia Ganz¹. ¹UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA; ²Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan. (*Tracking ID #1933474*)

BACKGROUND: The resource demands from the expanding cancer survivor population pose a significant challenge to health care systems worldwide. Guidelines recommend regular history, physical examination and mammography, but against routine surveillance imaging for detecting distant metastasis in survivors of breast cancer treated with curative intent. Studies of health services utilization of cancer survivors in Asia are limited. We examined patterns of physician visits and surveillance testing in a major cancer center in Taiwan, and assessed their relationship to various patient and physician factors and trends over time.

METHODS: All stage 0, I, II breast cancer cases were identified from the Taiwan Cancer Registry that were treated in the cancer center during 2002 to 2009. After excluding cases with recurrence, cases and institutional claims data were merged to measure the number of outpatient visits, breast imaging, and surveillance tests for detecting metastatic recurrence including serum tumor markers, abdominal imaging, chest X-ray, bone scan and PET, during the disease-free follow-up period from 13 to 60 months after initiation of breast cancer treatment. Poisson regression and logistic regression analyses were used to examine factors contributing to physician visits and testing, and separate analyses were conducted to look at individual patient cohorts from years 2002 to 2008 where sufficient follow up was available.

RESULTS: A total of 3,488 women ages 19 to 88 were identified from the registry. The number of breast cancer-specific physician visits in the 48-month follow up period (mean 18.7 per patient, SD 8.5) and the rates of surveillance testing to detect distant metastasis were greater than those recommended by ASCO/NCCN guidelines. Variables predicting the number of physician visits included age, cancer stage, year of treatment, hormonal therapy, chemotherapy, radiotherapy, whether the patient had seen psychiatry or medical subspecialties other than oncology, and the primary physician/specialty following the patient for breast cancer. After adjusting for covariates, the number of visits was highest among patients primarily followed by medical oncologists and lowest among those followed by breast surgeons (Figure 1). The adjusted 48-month visit rates decreased progressively from the 2003 cohort (mean 22.7) to the 2008 cohort (mean 17.7), related to an institutional effort in care coordination for breast cancer survivors. There was a significant decrease in the adjusted rate of tumor marker testing from the 2002 cohort (99.7 %) to the 2008 cohort (38.0 %) associated with the change in the institutional guideline (Figure 2). Greater number of visits was correlated with more frequent testing. Patients primarily followed by medical oncologists had the highest adjusted testing rates for tumor markers, bone scan, and abdominal imaging.

CONCLUSIONS: Early stage breast cancer survivors in Taiwan had high utilization of physician visits and surveillance testing for distant metastasis. This might be improved by greater coordination of care among breast cancer specialists. Implementation of an evidence-based guideline regarding the number of visits, imaging and tumor marker testing may be necessary to reduce the overutilization of testing.

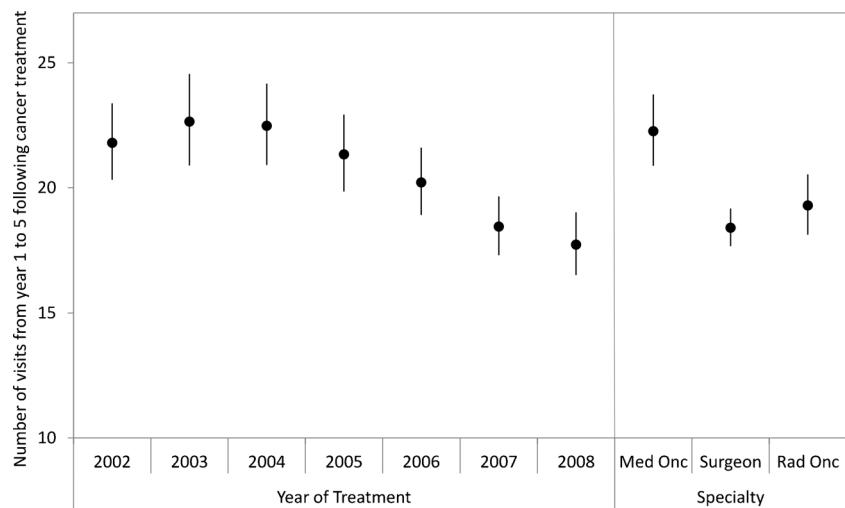

Figure 1. Post-treatment breast cancer-specific physician visits (year 1 to 5) by treatment year cohort and by specialty primarily following the patient

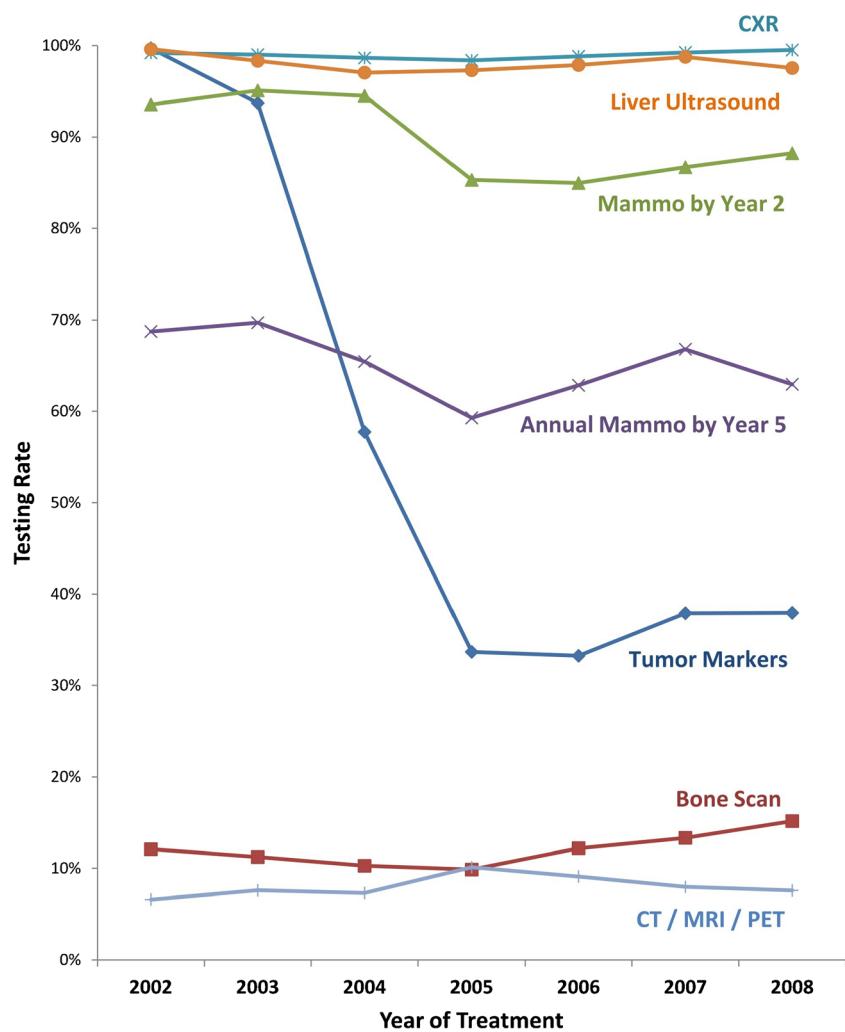

Figure 2. Adjusted testing rates by treatment year cohorts

PHYSICIANS' INABILITY TO ESTIMATE MEDICAL COSTS: A MULTISITE SURVEY David P. Miller¹; Dominic Johnson¹; Luke Kohan³; Michael Manogue⁴; Larry D. Case²; Hal Atkinson¹. ¹Wake Forest School of Medicine, Winston-Salem, NC; ²Wake Forest School of Medicine, Winston-Salem, NC; ³University of Virginia, Charlottesville, VA; ⁴Emory University, Atlanta, GA. (*Tracking ID #1937002*)

BACKGROUND: Practicing cost-effective medicine assumes that physicians know the cost of tests and treatments they order. Although physicians routinely order tests and procedures, it is unclear if they know how much these items cost. This uncertainty is particularly relevant given the increasing attention federal and commercial insurers have placed on cost containment and cost-effective medicine.

METHODS: To determine whether physicians are aware of common diagnostic and therapeutic costs, we conducted a survey at two large academic medical centers in the Southeast. Over a 2-month period (June–July 2013), we distributed surveys to all internal medicine residents and clinical faculty at Wake Forest University (Winston-Salem, North Carolina) and the University of Virginia (Charlottesville). We administered surveys in paper and electronic forms. The survey gathered basic demographic data, but to maintain confidentiality, no personal identifiers were collected. The survey included a mixture of multiple-choice and Likert scale items that assessed respondents' prior experience learning about and obtaining the costs of tests/procedures. We then asked respondents to estimate the cost of 20 commonly ordered diagnostic tests and procedures (i.e., Basic Metabolic Profile, CT Head without contrast, Transthoracic Echocardiogram) for both Medicare patients and commercially insured patients. Lastly, we asked them to estimate the cost of a hospital admission for a COPD exacerbation and a CHF exacerbation. For Medicare costs, we defined the true cost as its Medicare allowable charge.

RESULTS: Overall, 285 of 614 physicians completed the survey (180 faculty and 105 residents; response rate 46%). Two-thirds of physicians (193/285) stated they had never been given a price list for tests they commonly ordered. Additionally, two-thirds (193/285) reported they were "not at all confident" they could determine the cost of a test before they ordered it, and this lack of confidence did not differ between faculty and residents ($p=0.25$). Only 5% of residents (5/105) thought their attendings knew the costs of test/procedures "very well", and only 1% of attendings (2/179) thought their residents knew costs "very well." The most commonly reported sources of information about costs were personal experience (64%) and word of mouth (58%). In contrast, CME programs and medical school curricula were rarely cited as sources of cost information (21% and 7% respectively). Individual estimates for commonly ordered tests and procedures varied greatly. Very few physicians could estimate the cost of a test to within 25% of its actual Medicare allowable charge. On average, residents achieved this benchmark only 7.9% of the time compared to 10.7% for faculty ($p=0.02$). Only one-third of physicians (35%) could correctly identify the cost for more than 2 of the 22 surveyed items.

CONCLUSIONS: Physicians have little understanding of the true costs of the medical tests and procedures they order. Additionally, they report little confidence that they could determine the cost of a test before ordering it, and they rarely learn cost information from traditional sources of medical education. Without knowing this cost information, physicians are unable to make cost-benefit decisions. Efforts to improve the cost-effectiveness of medical care should include strategies for making cost information easily accessible to physicians.

POLYPHARMACY AND PHYSIOLOGIC FRAILTY IN HIV-INFECTED VETERANS Minhee Sung¹; Kirsha S. Gordon²; E. Jennifer Edelman^{3,2}; Amy C. Justice². ¹Yale University School of Medicine, New Haven, CT; ²VA Connecticut Healthcare System, West Haven, CT; ³Yale University School of Medicine, New Haven, CT. (*Tracking ID #1936987*)

BACKGROUND: HIV-infected (HIV+) patients are exposed to polypharmacy, the use of multiple medications concurrently, more frequently and at younger ages than their uninfected counterparts. While antiretroviral therapy (ART) sustains life for HIV+, non ART medication benefits are less clear and may contribute to frailty. Clinical research outside of HIV has found associations between polypharmacy and outcomes of frailty like fragility fractures, falls, and cognitive decline. Yet little research demonstrates the associations between polypharmacy and frailty in HIV+. We hypothesized that polypharmacy would be associated with increased risk of frailty among HIV+ veterans.

METHODS: We conducted a cross-sectional analysis of data from October 2009 to September 2010 from the Veterans Aging Cohort Study (VACS), which prospectively collects demographic, pharmacologic, and clinical data on HIV-infected patients receiving care through the Veterans Health Administration (VHA) system. The

sample was restricted to HIV+ on ART for at least 12 months. Active long-term medication use (defined as >90 days, allowing for 30 day gap between fill/refill) was determined using electronic pharmacy fill/refill data. Physiologic frailty was determined from self-reported survey items capturing physical shrinking, exhaustion, low physical activity, and slowness, and was categorized as pre-frail/frail vs. not frail. A logistic regression was used to assess the association between average long-term medication count and frailty after adjusting for demographics, VACS Index Score (a validated predictor of all-cause mortality), common medical comorbidities (including chronic obstructive pulmonary disease (COPD), diabetes mellitus, gastroesophageal reflux disease, hypertension, and osteoarthritis), substance use disorders (based on ICD-9 codes for alcohol and drug abuse and dependence), and mental illness.

RESULTS: The sample of 2281 HIV+ was predominately male (98%), with a mean age of 55 years, and was racially/ethnically diverse (67% black, 24% white, 8% Hispanic). The number of patients who were pre-frail or frail was 723 and not frail was 1558. The mean non ART medication count was 4 and the median and interquartile range was 3 (2,6). Each additional long-term non ART medication conferred a greater odds of being frail/pre-frail (OR [95% CI]=1.15 [1.12, 1.18]) compared to not frail. This relationship persisted in the adjusted model (OR [95% CI]=1.11 [1.07, 1.15]). Non ART medication count was the strongest predictor of being pre-frail/frail and osteoarthritis was the second strongest predictor (OR 2.23 [1.50, 3.33]). In addition, COPD was associated with being pre-frail/frail vs. not frail (OR=2.54[1.46,4.42]).

CONCLUSIONS: After adjusting for severity of illness among HIV+ on ART, for every additional long-term non ART medication the risk of being pre-frail or frail increases 11% after adjustment for severity of illness. Average long-term non ART medication count was the single best predictor of pre-frailty/frailty. Future studies must consider whether particular additional medications do more harm than good among HIV+ on ART.

POST-HOSPITAL DISCHARGE DELIRIUM AMONG OLDER ADULTS Priya Sunkara; Vanessa Ramirez-Zohfeld; Kenzie A. Cameron; Lee Lindquist. Northwestern University Feinberg School of Medicine, Chicago, IL. (*Tracking ID #1938704*)

BACKGROUND: As older adults are discharged from hospitals, they must remember intricate instructions on medications, follow-up appointments, and dietary changes. It is not surprising that seniors are frequently readmitted in the 30 day period following a hospitalization. Prior research has shown that cognition among seniors is impaired at discharge but improves the month following. We sought to determine how cognition changed in the 48 h following a hospitalization among older adults with mild cognitive impairment.

METHODS: Adults ages 65 and older who were admitted to the hospital acute medicine services for a non-cognitive related diagnosis. Older adults diagnosed with baseline mild cognitive impairment but were able to provide consent were included. Surveys were performed at hospital discharge and 48 h post hospitalization. The Montreal Cognitive Test (MOCA), Mini-Mental Status Examination (MMSE) were administered to evaluate cognition at baseline and 48 h following discharge. The Confusion Assessment Method (CAM) was used to assess delirium. Subjects were excluded if they had a positive screening Confusion Assessment Method during the day of discharge.

RESULTS: Baseline information was collected for 50 older adult subjects with mild cognitive impairment (mean age = 81.2) on day of hospital discharge. Mean cognition testing for subjects on day of hospital discharge was 21.2 MMSE and 15.22 MOCA. Subjects did not have positive CAM on day of discharge. Follow-up interviews were conducted 48 h following discharge, with five repeat attempts for each subject. Two subjects were re-hospitalized, and four subjects could not be reached within the 48 h follow-up window. At 48 h post-hospital discharge, 34% (15/44) subjects were positive on the CAM and found to have delirium.

CONCLUSIONS: At 48 h following hospital discharge, about 34% of older adults with mild cognitive impairment were found to have delirium. As delirium waxes and wanes, it is difficult to discern when the true onset of delirium occurred in the 48 h period following hospital discharge. Experiencing delirium after being discharged from a hospital is tremendously concerning. Older adults frequently are discharged home alone and expected to perform self-care functions (including medical management) following hospital discharge. It is unlikely that an older adult with active delirium would be able to reliably manage their self-care. Further research is needed to examine hospital and patient factors that contribute to the onset of post-hospital discharge delirium as well as interventions to support seniors with delirium following hospitalization. Transitional care interventions that focus on surrogates and increasing cognitive support during the post-hospitalization phase may be helpful for recently discharged older adults with mild cognitive impairment.

POTENTIAL IMPACT OF THE PADUA RISK ASSESSMENT MODEL ON THE USE OF VENOUS THROMBOEMBOLISM PROPHYLAXIS IN A TERTIARY MEDICAL CENTER IN THE UNITED STATES Bronwyn Small; Alexander Weick; David Paje; Muhammad Usman; Jainil Shah. Henry Ford Hospital, Detroit, MI. (*Tracking ID #1918465*)

BACKGROUND: The Joint Commission's core measures of hospital inpatient quality currently mandate that all patients receive prophylaxis against venous thromboembolism (VTE) unless there is a documented reason why it cannot be given. However, the most recent guidelines from the American College of Chest Physicians (ACCP) endorse the use of risk stratification tools such as the Padua Risk Assessment Model (PRAM) to identify who would likely benefit from pharmacologic or mechanical prophylaxis. PRAM was developed and validated in a university hospital in Padua, Italy, where 40 % of acute but not critically ill medical patients were found to be at high risk for VTE. We sought to determine the potential impact of the PRAM on the use of VTE prophylaxis among medical patients in an urban tertiary teaching hospital in the United States.

METHODS: Physicians were asked to complete a standard data collection tool during their initial evaluation of patients admitted to the general medical units of an 805-bed teaching hospital. The tool captured baseline demographic data and clinical variables included in the Padua Risk Assessment Model (PRAM). To assess mobility status, physicians were asked whether they anticipate reduced mobility for at least 3 days that is limited to no more than bed rest with bathroom privileges. A PRAM score of ≥ 4 was considered high-risk for VTE. The mode of VTE prophylaxis ordered was also recorded for each patient.

RESULTS: A total of 351 patients were enrolled in the study, 41 (11.7 %) were ordered therapeutic anticoagulation for other indications and were excluded from further analysis. Of the remaining 310 patients, 259 (83.5 %) were ordered pharmacologic prophylaxis and 29 (9.3 %) had mechanical prophylaxis ordered, but only 129 (41.6 %) were considered high-risk for VTE based on a PRAM score of ≥ 4 . Of the high-risk patients, 121 (93.8 %) had some kind of prophylaxis ordered, while 167 (92.3 %) of the low-risk patients had prophylaxis against VTE. If the PRAM was applied, 58 % (167/288) of the currently ordered prophylaxis would be considered unnecessary.

CONCLUSIONS: The proportion of acutely ill medical patients admitted to an urban tertiary hospital in the United States that are considered high-risk for VTE based on the Padua Risk Assessment Model is similar to the 40 % reported in the Italian cohort. Applying the PRAM to our population may result in a significant reduction in the use of venous thromboembolism prophylaxis. Future prospective validation of this tool should look at its impact on the clinical outcomes of thrombosis, bleeding and mortality.

PREDICTING MEDICAL SCHOOL AND INTERNSHIP SUCCESS: DOES THE QUALITY OF THE RESEARCH AND CLINICAL EXPERIENCE MATTER? Nathalie Paolino^{3,1}; Kent DeZee^{1,3}; Anthony R. Artino²; Ting Dong²; Steven Durnin¹. ¹Uniformed Services University, Bethesda, MD; ²Uniformed Services University, Bethesda, MD; ³Walter Reed National Military Medical Center, Bethesda, MD. (*Tracking ID #1938339*)

BACKGROUND: Selecting students for medical school admission remains a high-stake decision for applicants, schools, and society. Unfortunately, only a few applicant characteristics, such as the medical college admission tests (MCAT) and pre-matriculation grade point average (GPA), predict performance in medical school and subsequent clinical practice. This paper explores specific aspects of self-reported clinical and research experience on performance in medical school and graduate medical education (GME), hypothesizing that more experience will be associated with better performance.

METHODS: This is a retrospective cohort study from 7 consecutive classes at the Uniformed Science University (USU) in Bethesda, MD. The American Medical College Application Service (AMCAS) application was used to discern each student's self-reported clinical and research experience. Two authors (NP and KJD) developed a coding scheme for clinical experience (8 categories) and research experience (3 categories) by reviewing and classifying experiences reported by students until saturation was achieved. Both authors independently applied the coding scheme to all students' experiences and achieved excellent agreement ($\kappa > 0.9$ for both variables). Pre-matriculation GPA was obtained from transcripts. Study outcomes included years 1–2 GPA, years 3–4 GPA, cumulative medical school GPA, USMLE steps 1 and 2 scores, and PGY1 expertise and PGY1 professionalism scores (the latter two obtained from the student's program director after medical school graduation). A linear regression analysis was conducted for each outcome to determine the predictive

validity of clinical exposure and research exposure while controlling for pre-matriculation GPA. Effect sizes were used to assess the strength of significant associations.

RESULTS: Data were retrieved on 1,020 matriculants who had a mean pre-matriculation GPA of 3.41 (SD 0.3). There were several statistically significant, but small differences when comparing the various categories of clinical experience with no clinical experience across all 7 evaluated outcomes. The technician level group of clinical experience, which were students who worked in the healthcare field but did not have jobs requiring significant decision making opportunities regarding patient care (e.g., licensed practicing nurses, laboratory technicians, radiology technicians, orderlies and administrators) appeared to perform slightly worse during medical school with a decrease of 0.1 in cumulative GPA (based on a 4-point scale) in comparison to students without self-reported clinical experience ($p=0.004$), but the effect size (0.27) was small. This group also performed 5 points lower on the USMLE step 2 than students who did not report a clinical experience ($p=0.013$), but again the effect size (0.26) was small. Research experience quality appeared to have no significant predictive value for success in medical school and GME. Students who performed research, but did not produce a publication performed slightly better on USMLE Step 1 by 2.8 points ($p=0.012$) compared to students without research experience; however, the effect size (0.17) was trivial.

CONCLUSIONS: This retrospective study indicates that clinical and research experiences only weakly predict global and knowledge based outcomes in medical school and GME. Other variables besides pre-matriculation GPA and MCAT need to be examined to further risk stratify future students in their ability to be successful in medical school and clinical practice.

PREDICTORS OF ENGAGEMENT IN AN INTERNET SUPPORT GROUP FOR TREATING MOOD AND ANXIETY DISORDERS IN PRIMARY CARE Emily Rosenberger¹; Kaleab Abebe^{2,1}; Bea Herbeck Belnap²; Jordan F. Karp^{3,1}; Bruce L. Rollman^{2,1}. ¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA; ³University of Pittsburgh, Pittsburgh, PA. (*Tracking ID #1937516*)

BACKGROUND: Internet support groups (ISGs) that enable individuals with similar conditions to exchange information and support are emerging as an important self-help resource. Evidence suggests that ISG participants may experience less psychological distress, be more confident in their knowledge about their health and feel less socially isolated. Building an engaged ISG community is believed to be critical for an ISG's success, yet little is known about patient characteristics that predict engagement in an ISG for a mental health condition. We examined this issue using data collected as part of an ongoing NIMH-funded trial of online collaborative care for treating mood and anxiety disorders in primary care.

METHODS: Primary care providers from 26 Pittsburgh-area practices referred their depressed and anxious patients aged 18–75 to our trial in response to an electronic medical record system prompt generated during the office encounter. Protocol-eligible patients with Internet access who scored PHQ-9 and/or GAD-7 ≥ 10 were randomized to one of three groups, including one permitting access to our password-protected ISG. The ISG consists of: (1) moderated discussion boards where patients can pose questions and share treatment information and experiences; (2) links to reliable consumer health information, crisis hotlines, ask-an-expert, pharmacies and other resources; and (3) access to a proven-effective computerized cognitive behavioral therapy program. Patients were encouraged to login and participate via weekly email reminders and updates, quarterly contests to promote ISG discussions and the potential to earn status indicators for participating on discussion boards. We collected baseline data on mood (PHQ-9) and anxiety (GAD-7) symptoms, Internet use and sociodemographics, and we analyzed ISG server logs to measure user logins and creation of new discussion board posts and comments. We investigated predictors of ISG engagement, defined by a new post or comment, using zero-inflated Poisson regression to account for the sizeable proportion of patients who never engaged with the ISG.

RESULTS: Between 8/1/12–9/30/13, we randomized 175 patients to have ISG access. Their mean age was 43 (SD: 14), 82 % were female, 84 % were white, and their mean PHQ-9 and GAD-7 were 14.0 (4.7) and 12.7 (4.6), respectively. Overall, 77 % logged-in at least once (median: 5, range: 0–76) and 47 % made at least 1 post or comment. Those with higher levels of ISG engagement were more educated (RR > high school vs. \leq high school, 5.55, 95 % CI: 4.15–7.43; $p<0.001$); had received prior treatment for anxiety or depression (1.72, 1.24–2.38; $p=0.001$) including pharmacotherapy (2.75, 1.84–4.11; $p<0.001$); lacked social anxiety (4.94, 3.91–6.23; $p<0.001$) or PTSD (3.15, 2.05–4.83; $p<0.001$); and acknowledged having searched online about alternative medical treatments (1.30, 1.09–1.55; $p=0.003$). Furthermore,

whereas higher levels of mood symptoms were associated with decreased engagement (RR each 5-point increase in PHQ-9 score, 0.56, 0.51–0.62; $p<0.001$), higher levels of anxiety symptoms were associated with increased engagement (RR each 5-point increase in GAD-7 score, 1.34, 1.20–1.49; $p<0.001$).

CONCLUSIONS: Certain characteristics can identify depressed and anxious primary care patients who are more likely to engage with an ISG. Our trial is ongoing and will inform whether patient access to an ISG provided as part of a collaborative care intervention improves treatment outcomes.

PREDICTORS OF OPIATE PRESCRIPTION FOR LOW BACK PAIN IN OUTPATIENT AND EMERGENCY CARE SETTINGS Jessica Taff; Joanna Loewenstein; Linda Wang; Kate Schwartz; David Wei. New York University, New York, NY. (*Tracking ID #1938837*)

BACKGROUND: Low back pain (LBP) is a significant problem in both the outpatient and emergency department setting, costing the United States approximately 20–70 billion dollars per year. Opioids are commonly prescribed for the treatment of back pain, and their prescription has increased approximately 100 % from 1997 to 2006. The purpose of this study was to determine common predictors for opiate prescription in the outpatient and emergency department settings.

METHODS: We examined patient visits in the data from the National Ambulatory Medical Care Survey and National Hospital Ambulatory Medical Care Surveys for the years 2006–2010 for diagnosis of LBP. The primary outcome of interest was prescription of opioids for mechanical low back pain at a particular visit. Predictor variables of interest included insurance type, geographic region, healthcare setting (Emergency Department, Hospital based Outpatient Department, Ambulatory Care), and ethnicity. We performed multivariate logistic regression analysis to determine the relationships between these independent variables and opioid prescriptions for LBP.

RESULTS: We analyzed 12,355 patient visits for LBP in the emergency department [odds ratios (OR): 2.83, 95 % confidence intervals (CI): 2.36–3.38] and those from the south (OR: 1.41, 95 % CI: 1.04–1.91) or west (OR: 1.53, 95 % CI: 1.14–2.05) had increased likelihood of receiving opioid prescription for LBP. Additionally, patients of hispanic (OR: 0.62, 95 % CI: 0.48–0.80) and other (non-black/white) (OR: 0.57, 95 % CI: 0.35–0.93) ethnicities had decreased likelihood of receiving opioid prescriptions compared to white patients. There was no statistically significant relationship between insurance type and receipt of opioids.

CONCLUSIONS: Patients seen in emergency departments were more likely to receive opioids for low back pain; whites were more likely to receive them, and these effects were independent of insurance coverage. The prescriber practices based on location may be related to available resources, differences in presentation acuity, or differences in training based on setting. The racial discrepancies noted are also consistent with past studies. These findings may be reflective of differences in the provider-patient relationship among ethnic groups or the subjective expression of pain. We were surprised to find that insurance type is not a predictor of opioid prescription. Previous studies show that socioeconomic status (SES) is a predictor of opiate prescription. However, we were unable to control directly for SES as mean income was not included in the survey. Findings from our study contradict other recent studies from the same database that illustrate decreased opioid prescriptions with private insurance. This difference in result may reflect the imperfection of using insurance status as a proxy for SES. Data is also limited by confounders such as depression, other chronic comorbid conditions, and absence of imaging results in the workup for back pain. Despite these constraints, our results suggest clear and significant differences in opioid prescription practices among health care setting, geographic region, and ethnicity that need to be better explored in future studies.

PREPAREDNESS FOR DISCHARGE: A COMPARISON OF TWO MEASURES IN PREDICTING READMISSION Amanda Salanitro^{1,2}; Kathryn M. Goggins²; Samuel K. Nwosu³; Jonathan S. Schildcraut³; Sunil Kripalani². ¹VA Tennessee Valley Healthcare System, Nashville, TN; ²Vanderbilt University, Nashville, TN; ³Vanderbilt University, Nashville, TN. (*Tracking ID #1931231*)

BACKGROUND: Reducing hospital readmissions has been the focus of much attention recently. Patients who are readmitted may have been ill-prepared for discharge. One measure of preparedness, the Care Transition Measure, has been endorsed by the National Quality Forum; however, other measures of preparedness have been developed. We sought to determine which measure of preparedness better predicts readmission.

METHODS: The Vanderbilt Inpatient Cohort Study (VICS) is an ongoing prospective study that seeks to better define the relationship of social determinants

of health with patient outcomes after hospitalization. The study population includes adults hospitalized with acute coronary syndromes (ACS) and/or acute decompensated heart failure (ADHF). Following hospital discharge, patients completed a phone interview that included two measures of preparedness for discharge: Care Transition Measure-3 (CTM-3, range 0–100) and Brief PREPARED (B-PREPARED, range 0–22). Readmission during the 90 days following hospital discharge was analyzed as a binary outcome, as well as time in days to first readmission. We examined the correlation between the preparedness measures, preparedness and rate of readmission, and time to readmission, as well as the discriminative ability of the preparedness measures in predicting readmission.

RESULTS: Among 805 patients, the mean age was 60.3 (+12.6) years. The median preparedness was a score of 78 on the CTM-3 (interquartile range (IQR) 67–100) and 20 on the B-PREPARED (IQR 18–22). The CTM-3 and B-PREPARED measures were moderately correlated (Spearman's rho 0.4). In the 90 days following hospital discharge, readmission rates were significantly different by category of preparedness (Tables 1 and 2). Additionally, days to readmission were significantly different across categories of CTM-3 ($p=0.000$) and B-PREPARED ($p=0.016$) scores. In separate time-to-event models, CTM-3 and B-PREPARED scores each predicted readmission within 90 days (hazard ratios 0.735 and 0.785, respectively). Finally, the ability of B-PREPARED to discriminate between patients readmitted and those who were not was slightly better than CTM-3 (Somers' D 0.108 vs. 0.094). Inclusion of both measures increased the model's discriminative ability (Somers' D 0.128).

CONCLUSIONS: In this population 27–55 % of cardiac patients were readmitted within 90 days of hospital discharge, depending on their level of preparedness for discharge. As preparedness for discharge increased, readmission rates and days to readmission decreased. The B-PREPARED measure performed better than the CTM-3 in discriminating patients who are and are not readmitted within 90 days of hospital discharge.

Table 1. Rate of readmission by category of CTM-3 score

CTM score	N	Number of readmissions	% readmitted
0–56	62	25	40.3
57–78	354	123	34.7
79–100	389	105	27.0

Table 2. Rate of readmission by category of B-PREPARED score

B-PREPARED score	N	Number of readmissions	% readmitted
0–11	49	27	55.1
12–17	127	45	35.4
18–22	629	181	28.8

PRESCRIPTION DRUG UTILIZATION UNDER THE AFFORDABLE CARE ACT: WILL ESSENTIAL HEALTH BENEFITS ENSURE ACCESS TO MEDICINES IN “CLASSES OF CLINICAL CONCERN?” Joshua A. Rolnick. Stanford School of Medicine, Palo Alto, CA. (*Tracking ID #1940206*)

BACKGROUND: Under the Affordable Care Act (ACA), all new insurance plans sold through the health exchanges will be required to provide prescription drug coverage. Plans are not required, however, to include all drugs on their formularies. Under the final ACA regulations, each plan must offer at least as many different drugs in each treatment class (e.g. antihypertensives or antipsychotics) as the model, or “benchmark,” plan chosen by each state to define minimum coverage requirements. The Center for Medicaid and Medicare Services (CMS) chose not to require broader coverage for medications in any “classes of clinical concern.” In contrast to the ACA, CMS requires Medicare drug plans to cover “all or substantially all” drugs in six special classes: antidepressants, anticonvulsants, antineoplastics, antipsychotics, antiparkinson agents, and immunosuppressants. CMS selected these classes for special treatment due to concern that they contain drugs that are not easily substitutable and because patients may depend on continued access to their specific medications when switching insurance plans. Although this decision sparked significant public debate, little is known about utilization of protected class medications among would-be exchange enrollees.

METHODS: This study used data on prescription drug utilization and expenditures from the Medical Expenditures Panel Survey, a nationally representative survey of medical expenditures, demographics, and insurance characteristics. Data was used from the 102,767 respondents to the 2008–2010 survey. Subjects were respondents enrolled in small group or individual plans, combined with uninsured, as these are anticipated to supply the majority of exchange plan enrollees. Utilization was analyzed among nonelderly adults (age 18–64) with income \geq 138 % of the federal poverty line enrolled in small group plans, individual plans, or no insurance (uninsured) for at least 6 months of the year. Patterns in utilization and expenditures on drugs overall and in the classes of clinical concern were analyzed.

RESULTS: There were a weighted total of 37,900,000 individuals with small group insurance, 5,462,750 with individual insurance, and 28,269,384 uninsured. Under their current insurance state, these respondents had an average of 6.9 prescription fills per year, spending an average \$170 out-of-pocket per year on prescription drugs. Fifty-four percent filled at least one prescription drug per year. Classes of clinical concern accounted for a substantial percentage of expenditures. Antidepressants were used by 14,200,000 (8.5 % of population, 7.9 % of drug fills), anticonvulsants were used by 6,147,986 (3.7 % of population, 3.2 % of fills), antineoplastics by 1,437,719 (1.2 % of population, 0.8 % of fills), and antipsychotics by 1,437,719 (0.9 % of population, 0.7 % of fills). (The last two classes were utilized by too small a percentage to tabulate.) Thus, antidepressants, anticonvulsants, and antineoplastics were used by more than 1 % of the population and together accounted for 14 % of all annual drug fills. Utilization in protected classes was further analyzed by tabulating the number of drugs used in the three most common classes: anticonvulsants, antidepressants, and antipsychotics. Subjects used a total of 18 different anticonvulsants, 18 different antidepressants, and 34 different antipsychotics. In each case, the four most common medications accounted for less than 40 % of total drug fills. Of all medications, immunosuppressive agents was the most expensive class, with an average total expenditures of \$4,628 per fill and \$318 out of pocket. A second protected class, antipsychotics, was fourth most expensive, with an average \$1,518 per fill and \$171 out-of-pocket.

CONCLUSIONS: Among those eligible and likely to enrolle in the exchange plans, 54 % fill at least one prescription per year. HHS chose not to follow the Medicare part D rules and require plans to cover all or nearly all medications in any specific classes, including the “classes of clinical concern.” However, among potential enrollees, medications in these classes account for a sizable minority (14 %) of all fills. Enrollees further use a variety of medications in each class, and the classes of concern include some of the most expensive medications available. If exchange plans offer formularies with only a limited number of medications, many enrollees may be unable to obtain coverage for their current medications in these classes. Limitations of this study include the fact that exchange plan enrollees may not be representative of current small group and individual enrollees or the uninsured. Nevertheless, this study contains the most detailed data to date on an important question in prescription drug coverage under the Affordable Care Act.

PREVALENCE OF MENTAL HEALTH CONDITIONS AND ASSOCIATED PATTERNS OF HEALTH CARE UTILIZATION AMONG HIGH COST VA PATIENTS

Donna M. Zulman^{2,4}; Grace Hunter¹; Jean Yoon^{3,2}; Daniel Blonigen²; Steven Asch^{2,4}. ¹Stanford University School of Medicine, Stanford, CA; ²VA Palo Alto Health Care System, Menlo Park, CA; ³VA Palo Alto Health Care System, Stanford, CA; ⁴Stanford University, Stanford, CA. (Tracking ID #1937115)

BACKGROUND: Mirroring national trends, the most costly 5 % of patients in the Veterans Administration (VA) system account for almost half of total health expenditures. These patients have complex health care needs; the vast majority have at least two coexisting chronic conditions and almost half have at least one diagnosed mental health (MH) condition. While several studies have shown that MH conditions are associated with higher utilization of health services, very little research has focused on the role of these conditions among high-cost patients. The aim of this study was to investigate the influence of MH conditions on health care utilization patterns among high-cost VA patients.

METHODS: We obtained total VA health care costs and utilization by source (inpatient, outpatient, pharmacy, and non-VA contract care) for the costliest 5 % of patients ($N=261,699$) who received care within the VA in fiscal year 2010. We used ICD-9 diagnostic codes to assign each patient to one of five mutually exclusive groups based on a hierarchy of MH diagnoses: 1) No MH Condition; 2) Serious Mental Illness (SMI); 3) Substance Use Disorder (SUD); 4) Post-Traumatic Stress

Disorder (PTSD); and 5) Depression. We used multivariable linear regression to examine the association between the MH diagnostic group and: 1) hospital admissions and length of stay; 2) outpatient utilization (number of visits for primary, specialty, emergency, and mental health care); 3) costs for inpatient services (MH, residential/domiciliary, medical/surgical, and long term care); and 4) costs for outpatient services (MH, medical/surgical, diagnostic, and pharmacy) after adjusting for patient age, sex, race/ethnicity, marital status and documented homelessness. Finally, for each cohort we calculated the proportion of costs generated by MH care.

RESULTS: Compared with the patients without a diagnosed MH condition, patients with one or more MH diagnoses were statistically significantly younger in age and more likely to be female, not married, without supplemental insurance, and homeless.

Among patients with MH conditions, patients in the PTSD and Depression groups had higher rates of most chronic conditions and had a higher level of multimorbidity than patients in the SMI and SUD groups. Compared to patients with SMI and SUD, patients in the PTSD and Depression groups had higher numbers of primary and specialty care visits and longer medical/surgical lengths of stay. In contrast, patients in the SMI and SUD groups had higher MH utilization (e.g., MH visits, behavioral length of stay (LOS), and residential/domiciliary LOS) than the PTSD and Depression groups. These utilization patterns translated to a greater proportion of costs generated by MH care among patients in the SMI and SUD groups (41 % and 31 %, respectively) compared to patients in the PTSD and Depression groups (18 % and 11 %, respectively).

CONCLUSIONS: Among high-cost VA patients with MH conditions, utilization and cost patterns indicate that patients with SMI and SUD incur a greater proportion of care and costs related to their MH conditions, when compared to patients with PTSD or Depression. These findings can help inform patient stratification algorithms and service delivery for intensive primary care programs focusing on high-cost patients.

PREVALENCE OF PRESCRIPTION OPIOID ABUSE/OVERUSE AMONG CHRONIC OPIOID THERAPY (COT) PATIENTS: USE OF NATURAL LANGUAGE PROCESSING (NLP) WITH VALIDATION REVIEW TO IDENTIFY OPIOID ABUSE IN ELECTRONIC MEDICAL RECORD CLINICAL NOTES

Michael VonKorff¹; David Carrell¹; David Cronkite¹; Roy Palmer²; Timothy R. Hyland²; Kathleen Saunders¹; David E. Gross¹. ¹Group Health Cooperative, Seattle, WA; ²Pfizer Inc., New York City, NY. (Tracking ID #1938636)

BACKGROUND: A review of studies in unrepresentative patient populations enrolled in clinical research reported that only 0.27 % of 2613 chronic non-cancer pain patients who received opioids for at least 6 months became addicted to opioids or used opioids inappropriately. More recent studies in community practice settings have reported much higher rates of prescription opioid addiction and abuse, with prevalence rates ranging from 4 to 26 %. It is not known whether chronic opioid therapy (COT) patients who become addicted to, or overuse, medically prescribed opioids can be identified through review of clinical notes in electronic medical records. Use of natural language processing (NLP) to efficiently identify patients with prescription opioid addiction, abuse or overuse has potential applications for epidemiologic research on risks of prescription opioid addiction in community practice, for patient monitoring in clinical care, and for quality assurance.

METHODS: Among 22,143 Group Health chronic non-cancer pain patients receiving COT in 2006–12 (defined as 70+ days supply of opioids in a 90 day interval), we developed an NLP system using a custom dictionary of 792 terms to identify mentions of opioid addiction, abuse and overuse in clinical notes. For COT patients with documents that were NLP positive, we manually reviewed up to four positive records per patient with a computer-assisted chart review tool highlighting relevant text to validate the presence of opioid addiction, abuse or overuse. The inter-rater reliability for 100 independently reviewed records was kappa = 0.86, with 97 % agreement on validation status.

RESULTS: Among 3663 NLP positive records, 77 % were manually validated as indicating opioid addiction, abuse or overuse. Among NLP positive records, 75 % documented current or very recent opioid addiction or abuse, 14 % documented opioid overuse only, and 11 % recorded only a diagnostic label or code. Among NLP positive records that were not validated, common reasons for non-validation were non-recent history of opioid abuse (41 %), documentation of discussion of potential addiction risks (35 %), “boilerplate” text that mentioned addiction or abuse risks without reference to the patient (9 %), and reference to opioid abuse by a family member (6 %). Among 22,143 patients who received chronic opioid therapy for at least one quarter in 2006–12, 6.8 % had NLP identified and validated documentation of prescription opioid addiction, abuse or overuse. The prevalence rate was 7.5 % among those

receiving COT for at least 6 months ($N=17,062$). The prevalence rates for opioid addiction, abuse or overuse were similar for males and females who received COT for at least 6 months, but differed by age (12.3 % for persons age 18–44, 5.8 % for persons age 45–64, and 2.8 % for persons age 65+).

CONCLUSIONS: Efficient identification of clinician documented prescription opioid addiction, abuse and overuse was feasible using NLP techniques that were further enhanced with computer-assisted manual validation. Clinician recognized prescription opioid addiction, abuse or overuse was common among COT patients, with the highest rates observed among younger patients, but with notable risks among middle aged and older COT patients. Extensions of this research will use NLP to identify clinical indicators of opioid addiction (e.g. opioid craving and hazardous use).

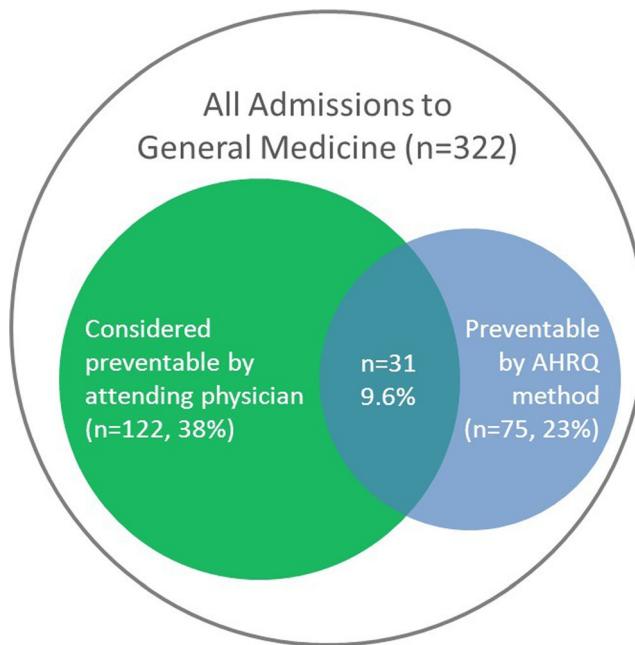

PREVENTABLE ADMISSIONS ON A GENERAL MEDICINE SERVICE: PREVALENCE AND CAUSES Nirav Vakharia; James Pile; Erik Howell; Sang Been N. Hong; Kristen Boyer; Kelly Nottingham; Jacqueline Fox; Neha R. Pidatala; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (*Tracking ID #1935775*)

BACKGROUND: Rates of preventable admissions will soon be publicly reported and used in calculating performance-based payments. The current method of assessing preventable admissions, the AHRQ Ambulatory Care Sensitive Conditions (ACSC) admission rate, is drawn from claims data and was originally designed to assess population—not patient—level access to care. It has not been validated for assessing the performance of individual healthcare organizations. Specific causes of preventable admissions have not been well studied.

METHODS: We examined 322 serial admissions to a general medicine service at an academic medical center in December 2013. For each admission, the attending physician was surveyed regarding preventability of the admission, defined as the presence of any factor during the 2 weeks prior to admission which, if addressed in the outpatient setting, could have averted the hospitalization. Demographics, principal diagnosis ICD-9 code, and readmission status were gathered from the electronic medical record. Prior to the study, a list of preventability factors drawn from past research and categorized by system, clinician, and patient factors was adapted with input from hospitalist, primary care, and emergency physicians. For admissions deemed preventable, the physician selected a factor from the list which most contributed to the hospitalization and rated the feasibility of prevention on a 4 point scale (very easy to very difficult). For the same admissions, the AHRQ ACSC methodology was applied to determine the claims-derived preventable admission rate for admission.

RESULTS: Of the 322 admissions, 63 (20 %) were readmissions. Physicians rated all 322 admissions and classified 122 (38 %) as preventable, of which 31 were readmissions. Application of the AHRQ ACSC methodology identified 75 (23 %) preventable admissions. Thirty-one admissions (10 %) were classified as preventable by both methods, and the majority of admissions considered preventable by the AHRQ ACSC method (44/78) were not considered preventable by physician assessment. Compared to our method, the AHRQ ACSC method's sensitivity was 25 % and specificity was 78 %. Of the 122 preventable admissions, physicians chose patient factors in 52 (43 %), specifically non-adherence (17 %), mental health/substance abuse (8 %), poor health literacy (5 %), secondary gain from hospitalization (3 %), and poor home support (1 %). System factors were chosen in 34 (28 %), specifically inpatient management easier than outpatient (11 %), inadequate care at a nursing facility (5 %), inability to access outpatient providers (2 %), and complication from previous admission (1 %). The remaining 36 (30 %) were assigned to clinician factors, including threshold for admission too low (9 %), inadequate follow-up (8 %), inappropriate diagnosis/treatment (7 %). Of the 122 preventable admissions, 63 (52 %) were considered very or somewhat easy to prevent. Preventable admissions for which clinician factors were chosen were considered the easiest to prevent, with 67 % assigned very or somewhat easy; whereas those for which patient factors were chosen were considered the most challenging, with 38 % assigned very or somewhat easy to prevent.

CONCLUSIONS: A large proportion of admissions to a general medicine service appeared preventable, and only a small percentage of these were readmissions. Patient factors were most commonly cited, and these were also rated the most difficult to address. AHRQ's Ambulatory Care Sensitive Conditions rate showed poor sensitivity and moderate specificity as compared to our method of direct physician assessment. These findings warrant further evaluation of the ACSC rate for use in pay for performance programs, and additional investigation into the factors implicated in preventable admissions.

PRIMARY CARE PATIENTS' USE OF MOBILE HEALTH (MHEALTH) TOOLS Amy Bauer¹; Tessa Rue^{2,3}; Gina A. Keppel^{3,4}; Allison Cole^{3,4}; Laura-Mae Baldwin⁴; Wayne Katon¹. ¹University of Washington, Seattle, WA; ²University of Washington, Seattle, WA; ³University of Washington, Seattle, WA; ⁴University of Washington, Seattle, WA. (*Tracking ID #1925955*)

BACKGROUND: Mobile health (mHealth) has emerged rapidly as a multibillion dollar industry with tens of thousands of consumer smartphone health applications (apps) available, most of which have not been subject to scientific study or regulatory approval. The potential for mHealth tools to represent an important advancement in chronic disease care (i.e., via education about chronic illness, appointment reminders, monitoring disease control, facilitating behavior change) has been recognized. Although primary care is the setting where most chronic disease care occurs, the patterns of mHealth use among primary care patients have not been documented. This study aimed to determine the prevalence of mHealth use among primary care patients and examine demographic and clinical correlates.

METHODS: All adult patients who presented to one of 6 primary care clinics located in 4 states (Washington, Wyoming, Alaska, Montana) in a practice-based research network during a 2-week period received an anonymous survey that assessed mobile phone ownership, mHealth use including frequency and characteristics of use, sociodemographic characteristics (age, gender, race/ethnicity, health literacy), chronic medical conditions, and current depressive symptoms (PHQ-2). Data analysis employed descriptive statistics and multivariate mixed logistic regression.

RESULTS: 918 patients responded to the survey (estimated response rate: 67.4 %). Mobile phone ownership was nearly ubiquitous (91 %), with the majority of patients (55 %) owning a smartphone. Mobile health use was common (70 % of smartphone owners; 39 % of all patients). Most mHealth users were seeking health information (92 %) and many were using mHealth applications (57 %) or tracking a health condition (54 %). Compared to young adults (ages 18–24), smartphone ownership and mHealth use were each less common among adults in every age group over 45 years (adjusted ORs 0.07–0.39, $p < 0.001$). Health literacy, chronic medical conditions, and depression were not associated with mHealth use. Most mHealth users were infrequent users and most (61 %) reported using an app for a short period of time then stopping, often (48 %) because it was too time-consuming. The most popular types of apps were general health apps (36 %) followed by fitness (15 %) and diet (10 %) apps, with very few patients (3 %) using apps for chronic disease management. Fewer than 10 % of mHealth users learned about mHealth apps from their healthcare provider, with 69 % reporting that it was 'not at all' or only 'a little bit' important for their providers to know about their use of health apps. However, patients rated appointment reminders as the most useful potential feature, followed closely by medication reminders, general health information, and health tracking.

CONCLUSIONS: Smartphone ownership and mHealth use are common among primary care patients. Adoption lags among older adults, however patients with limited health literacy and chronic conditions use mHealth technologies at similar rates as their counterparts, supporting the potential role of mHealth in improving disease management among certain groups in need. Few patients believe it is important for healthcare providers to know about their mHealth use; however, providers who do discuss mHealth use with patients may be able to elicit important information about patients' self-management activities, which may help these providers to be more adept in the support they offer for chronic disease care.

PRIMARY CARE PHYSICIANS' READINESS TO PROVIDE ACCOUNTABLE CARE AND ACHIEVE THE TRIPLE AIM Petra W. Rasmussen; Shreya Patel; Anne-Marie J. Audet; Michelle M. Doty. The Commonwealth Fund, New York, NY. (*Tracking ID #1938208*)

BACKGROUND: Little is known about the extent to which primary care practices are implementing accountable care strategies to provide enhanced access, care management and outreach to individual patients and panel populations; coordinated care among various providers within and outside the practice; engage patients in their care; and track and monitor quality and utilization. This study provides a snapshot of current readiness of primary care physicians to provide accountable care and discusses whether payment incentives and additional practice redesign resources can foster transformation.

METHODS: Data come from the 2012 Commonwealth Fund International Health Policy Survey of Primary Care Physicians administered to a nationally representative sample of 1,012 primary care physicians in the United States. We use 30 items to create composite scores to assess whether physicians have capacity in five domains that are essential for accountable care: 1) providing enhanced access; 2) collecting actionable data to manage individual patients and patient populations; 3) collecting

and using quality of care data; 4) managing and coordinating patient care within and outside their practice; 5) patient outreach. We then looked at three aspects of practices to see if certain attributes and activities led to increased provision of accountable care: 1) organization; 2) technical assistance; 3) payment.

RESULTS: Primary care physicians who were part of integrated delivery systems were more likely to report coordinating and managing the care for their patient populations, including the care provided by physicians outside of their practice. Practice size also affected the provision of care across all domains, with larger practices being more likely to report accountable care functionalities. Having formal arrangements to share quality improvement consultants and/or technical support for clinical information systems was also an important predictor of a practice's capacity to provide accountable care. Practices that were eligible to receive targeted financial incentives for activities such as making home visits and non-face-to-face interactions with patients were more likely to manage and coordinate patient care within and outside of their practice, provide patient outreach, and be able to access and review quality of care data.

CONCLUSIONS: Significant gaps are currently observed in primary care physicians' readiness to meet functionalities that will be required to be fully accountable for the quality of care, health outcomes and resource use for their panel of patients. The results from the study will inform policy makers and stakeholders as they develop performance targets, technical assistance programs, and new payment models in order to help guide practices as they transform into models of accountable care. Our findings also indicate that increased attention must be paid towards the organization and coordination of delivery systems, and technical assistance. These elements will be essential in fostering a culture of effective partnerships among providers to ensure patients receive coordinated services according to their needs and the successful implementation of best practices for engaging patients in the management of their health.

Practice Profile by Accountable Care Capacity, U.S. Primary Care Physicians, 2012 (Adjusted Percentages)

PRIMARY CARE PROVIDER EXPERIENCE WITH A NEW HEALTH INFORMATION TECHNOLOGY TOOL TO FACILITATE BETWEEN VISIT MEDICATION MANAGEMENT Richard W. Grant³; Leila H. Borowsky¹; Jeffrey M. Ashburner¹; Michael Jernigan²; Steven J. Atlas¹. ¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Kaiser Permanente, Oakland, CA. (*Tracking ID #1937532*)

BACKGROUND: Lack of timely medication intensification and inadequate medication safety monitoring are two prevalent and potentially modifiable barriers to effective and safe care for chronic conditions. We developed a novel health information technology tool (Medication Metronome) designed to support non-visit based medication management. Integrated into an existing electronic medical record, this tool enabled primary care physicians (PCPs) to schedule future laboratory monitoring when ordering medication changes (initiation or dose adjustment) for diabetes, hypertension, and/or hyperlipidemia management. We hypothesized that scheduling follow-up laboratory monitoring (e.g. HbA1c 3 months after starting metformin) would reduce delays in further medication titration by obviating the need for a return visit solely to obtain laboratory tests.

METHODS: Forty-four PCPs from two practices within an academic primary care network were randomized to usual care (control group) or to use the Medication Metronome tool. For scheduled laboratory orders, Medication Metronome automatically sent the patient a letter with a lab slip 1 week prior to the lab due date. If the test was not performed, a second letter and lab slip were sent 1 week after the lab due date. The PCP received an alert in the results management section of the electronic health record 3 weeks after the lab due date if it still had not been performed. We report here the results of PCP surveys administered at the end of the 1-year study assessing medication management workflow during the study period. Responses from intervention and control physicians were compared using Fisher's exact test.

RESULTS: Among PCPs, 86 % (19 of 22) in the control group and 91 % (20 of 22) in the intervention group completed surveys. The proportion of PCPs who reported spending more than 20 min during a typical half-day session on medication management was greater for intervention vs. control PCPs (60 % vs. 47 % for diabetes management; 60 % vs. 42 % for hypertension; and 60 % vs. 42 % for hyperlipidemia), although these differences did not reach statistical significance ($p>0.05$). The proportion of PCPs who reported improvement in their ability to start or change medications for a patient outside of the context of an office visit was 35 % in the intervention group compared to 26 % in the control group ($p=0.86$). Among intervention group PCPs, 30 % indicated that Medication Metronome improved their ability to provide timely medication management, with the remaining 70 % reporting no change. Most intervention group PCPs (80 %) reported barriers to using the Medication Metronome module including poor alignment with current visit-based reimbursement practices.

CONCLUSIONS: Implementation of a novel tool to support non-visit based follow-up after medication changes had only a modest impact on PCP workflow. Despite consenting and enrolling in the clinical assessment trial, most intervention PCPs did not take full advantage of the tool. Among reported

barriers to wider use was the misalignment of visit-based reimbursement and productivity requirements with a non-visit based model of care. Health policy and reimbursement changes that support overall quality of management and that recognize non-visit care might encourage greater adoption of innovative tools to support visit-independent medication management.

PRIMARY PREVENTION OF CARDIOVASCULAR DISEASE: ARE WE TARGETING THE RIGHT PATIENTS? Kevin Selby¹; David Nanchen¹; Pedro Marquez-Vidal¹; Reto Auer¹; Baris Gencer²; Giulio G. Stefanini³; Lorenz Räber³; Roland Klingenberg⁴; Jacques Cornuz¹; Pierre Vogt¹; Peter Jüni³; Christian M. Matter⁴; Stephan Windecker³; Thomas Lüscher⁴; François Mach²; Nicolas Rodondi³. ¹University of Lausanne, Lausanne, Switzerland; ²University of Geneva, Geneva, Switzerland; ³University of Bern, Bern, Switzerland; ⁴University Hospital Zurich, Zurich, Switzerland. (*Tracking ID #1929718*)

BACKGROUND: Guidelines for the primary prevention of cardiovascular disease (CVD) are based on the identification of high-risk patients who are most likely to benefit from medications such as aspirin and statins. Several cardiovascular risk calculators are used in Europe, but their ability to identify those who will develop CVD has not always been demonstrated in external validation cohorts. Furthermore, the implementation of primary prevention guidelines for statin and aspirin prescription is less well studied.

METHODS: We collected baseline information regarding cardiovascular risk factors and medication use for 3,848 consecutive patients admitted with acute coronary syndrome (ACS) between 2009 and 2013 to four university hospitals in Switzerland. Ten-year cardiovascular mortality was computed using the European Systemic Coronary Risk Evaluation (SCORE) from the European Society of Cardiology (ESC) guidelines; 10-year fatal and non-fatal risk of CVD using the American College of Cardiology/American Heart Association (ACC/AHA) guidelines; and 10-year fatal and non-fatal risk of coronary heart disease using the Swiss Society for Atherosclerosis (AGLA) guidelines. Use of aspirin and statins before hospitalization was stratified by risk level and compared with recommended use of ESC, ACC/AHA and AGLA guidelines.

RESULTS: 2,810 (73 %) patients had no previous history of CVD. Using ESC guidelines, 771 (20 %) had a 10-year CVD mortality risk below 1 %, compared to 1091 (28 %) with a 10-year CVD risk below 5 % using the ACC/AHA guidelines, and 1331 (35 %) with a 10-year CHD risk below 10 % with AGLA guidelines. Only 1150 (30 %) were taking a statin and 1278 (33 %) aspirin before hospitalization for ACS. The additional proportion of patients in whom a statin would have been indicated reached 50 % using ESC, 46 % using ACC/AHA, and 38 % using the Swiss AGLA guidelines (Figure).

CONCLUSIONS: Among patients presenting with ACS to Swiss hospitals, one-fifth to a third are classified as low risk using risk calculators. The use of statins and antiplatelet medications before hospitalization is low in patients presenting with ACS. This is in contrast with the large number of patients for whom a statin would have been recommended with full compliance to primary prevention guidelines.

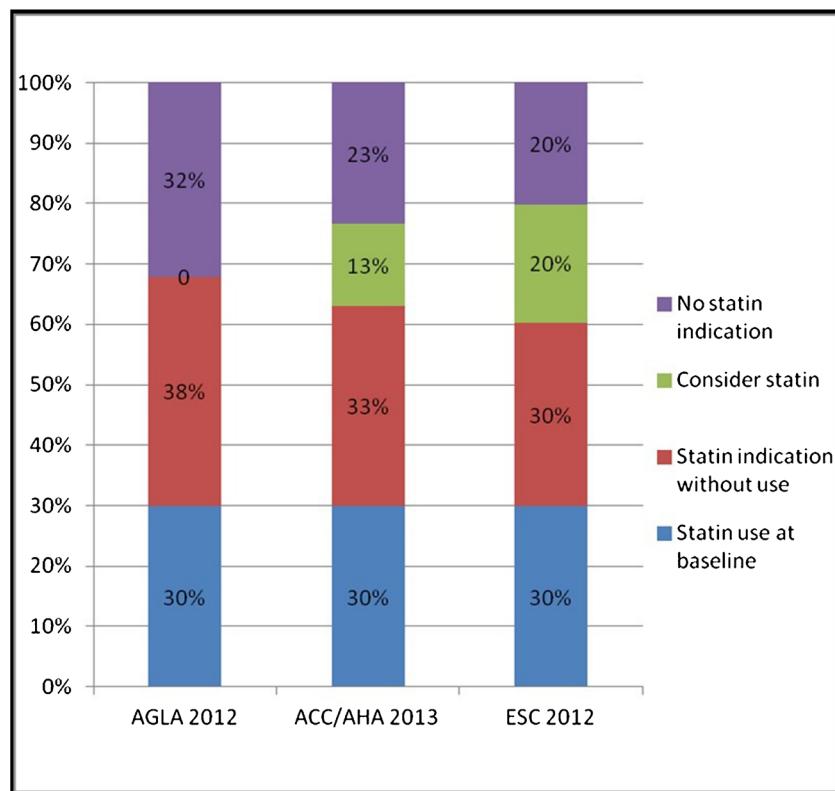

Figure: Patients taking a statin on arrival, those with a clear statin indication, those for whom a statin should be considered, and those with no statin indication using different guidelines ($n=3848$). AGLA: Swiss Society of Atherosclerosis. ACC: American College of Cardiology. AHA: American Heart Association. ESC: European Society of Cardiology.

PRIORITIZING CONCEPTS OF CLINICAL REASONING John Musgrave¹; Jason L. Morris^{1,2}; Ryan Kraemer^{1,2}; Carlos Estrada^{2,1}. ¹University of Alabama at Birmingham, Birmingham, AL; ²Birmingham VAMC, Birmingham, AL. (Tracking ID #1928091)

BACKGROUND: The field of cognitive psychology has informed our understanding of how physicians think and make decisions. However, little is known about prioritizing clinical reasoning concepts for teaching. We aim to prioritize commonly

described clinical reasoning concepts to facilitate the teaching of clinical problem solving skills.

METHODS: Consensus development. **First**, two authors compiled an extensive list of clinical reasoning concepts from seminal narrative reviews. **Second**, seven clinical educators reviewed the list for additions and voted items for inclusion in a systematic review; items with <5 votes were excluded. **Third**, eight clinical educators ranked the remaining items (most important concept first, least important concept last) using a card-sort method. This technique represents a robust means of measuring opinion enhanced by a visual-motor cognitive dimension. For analysis we used the rank-order centroid method for assigning weights based on ordinal preference (order in card sort). For example, if three items are ranked as 1st, 2nd, and 3rd; their relative weights are 0.61, 0.28, and 0.11. The main outcome was the sum of weights assigned to each clinical reasoning concept by each clinical educator.

RESULTS: Of 49 clinical reasoning concepts identified, 24 received <5 votes and five were deemed synonyms. The remaining 20 clinical reasoning concepts and the

percent of total weight assigned to each concept are shown in the Table (sum of weights = 100 %). The top four concepts were problem representation, diagnosis, dual-process thinking, and illness scripts. Excluded concepts were: cognitive load, feedback loops, patient story, test interpretation, deliberate practice, concept maps, prior probability, mental simulation, hypothetico-deductive model, decision analysis, coaching, Bayesian reasoning, and dynamic model.

CONCLUSIONS: Through a systematic consensus development, we prioritized a list of commonly described clinical reasoning concepts for inclusion in a systematic review.

Item	Weighth	Item	Weight
Problem representation	11 %	Slowing down	5 %
Diagnosis	8 %	Cognitive error	4 %
Dual-process thinking	8 %	Framing	3 %
Illness scripts	8 %	Premature closure	3 %
System 1 (non-analytic)	7 %	Bias	3 %
System 2 (analytic)	6 %	Anchoring	2 %
Hypothesis generation/ refinement	6 %	Naturalistic decision-making	2 %
Problem categorization	6 %	System error	2 %
Flexibility	6 %	Context specificity	2 %
Metacognition	5 %	Overconfidence	1 %

PROACTIVE OUTREACH OF TOBACCO CESSATION TREATMENT TO DISADVANTAGED SMOKERS AFTER A PRIMARY CARE VISIT: A RANDOMIZED CONTROLLED TRIAL Jeffrey A. Linder^{1,3}; Jennifer Haas^{1,3}; Nancy A. Rigotti^{2,3}; Elyse R. Park^{2,3}; Emily Kontos^{4,5}; Irina Gonzalez¹; Elissa Klinger¹; Lucas Marinacci¹; Phyllis Brawarsky¹; Stella St. Hubert¹. ¹Brigham and Women's Hospital, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Harvard Medical School, Boston, MA; ⁴Harvard School of Public Health, Boston, MA; ⁵Lung Cancer Disparities Center, Boston, MA. (Tracking ID #1923076)

BACKGROUND: Low socioeconomic status (SES) and minority smokers have less access to tobacco treatment. Proactive outreach to these smokers after a primary care (PC) visit, using interactive voice response (IVR) technology, telephone counseling and free nicotine replacement (NRT), might promote treatment access and smoking cessation. In a RCT, we compared this tobacco treatment program for low SES and minority smokers to usual care.

METHODS: African-American, Hispanic, or white adults with a recent PC visit to a large health care delivery system were eligible if they were documented as smokers in the electronic health record and lived in a low-moderate income census tract. The IVR system made up to 15 proactive calls per person to confirm smoking status and offer study participation. Enrollees were randomized to usual care or IVR-mediated intervention (up to 4 calls with a bilingual tobacco treatment specialist, 6 weeks of free NRT, and referral to community resources to reduce life stressors). The primary outcome was self-reported past 7-day smoking status 9 months after randomization, with patients not reached counted as smokers. Multivariate regression was used to test whether the intervention was more effective in any subgroup.

RESULTS: The IVR system attempted to contact 8547 patients, of whom 116 (1 %) were ineligible because they reported not smoking, 5553 (65 %) were not reached by IVR, 2170 (25 %) declined participation, and 708 (8 %) consented and were randomized. To date, 542 have completed outcome assessment (70 % response rate). Participants had a median age of 50 year. (range 19–82); 23 % were African American and 17 % were Hispanic; 34 % had no more than a high school education. At 9-month follow-up, self-reported quit rate was 8.6 % in the control group and 14.9 % in the intervention group ($p=0.02$). Hispanics were more likely to quit than whites ($p=0.008$).

CONCLUSIONS: An integrated program using IVR outreach and offering centralized telephone smoking cessation counseling, free NRT, and linkage to community resources may be an effective treatment strategy for engaging disadvantaged populations of smokers, particularly Hispanic smokers.

PROFILING MEDICAL SCHOOL LEARNING ENVIRONMENTS ACROSS CULTURES USING ONE NEW SCALE Sean Tackett¹; Hamidah Abu Bakar²; Nicole A. Shilkofski³; Niamh Coady⁴; Krishna Rampal³; Scott Wright¹. ¹Johns Hopkins Bayview Medical Center, Baltimore, MD; ²Cyberjaya University College of Medical Sciences, Sepang, Malaysia; ³Perdana University Graduate School of Medicine, Serdang, Malaysia; ⁴Perdana University Royal College of Surgeons in Ireland School of Medicine, Serdang, Malaysia. (Tracking ID #1928927)

BACKGROUND: In many countries, there is growing interest in improving medical school learning environments; however accurately assessing learning environments is a challenge. As international partnerships in medical education become more common, ensuring that effective learning environments are translated across borders will become more relevant. The goal of this study was to test the ability of a new learning environment assessment tool, the Johns Hopkins Learning Environment Scale (JHLES), to detect differences in pre-clerkship learning environments at 4 medical schools. Two schools are new international partnerships in Malaysia: (i) Perdana University Graduate School of Medicine (PUGSOM)—a graduate-entry program run by Johns Hopkins University School of Medicine (JHUSOM), and (ii) Perdana University-Royal College of Surgeons in Ireland School of Medicine (PU-RCSI)—a school-leaver program run by RCSI. Perdana schools matriculated their first students in the fall of 2011. The other two medical schools were Cyberjaya University College of Medical Sciences (CUCMS), a school-leaver program in Malaysia, and JHUSOM a graduate-entry program in Baltimore, MD.

METHODS: Both first and second year students responded anonymously to surveys at the end of the academic year. All surveys included the JHLES, a 28-item survey using 5-point Likert scale response options. During development at JHUSOM, factor analysis resulted in 7 domains (listed with respective Cronbach's α): (1) community of peers ($\alpha=0.91$), (2) faculty relationships ($\alpha=0.80$), (3) academic climate ($\alpha=0.86$), (4) engagement ($\alpha=0.82$), (5) mentorship ($\alpha=0.74$), (6) acceptance and safety ($\alpha=0.58$), and (7) physical space ($\alpha=0.66$). Surveys at the 3 Malaysian medical schools also included the Dundee Ready Educational Environment Measure (DREEM), the most widely-used method to assess learning environments internationally. DREEM is a 50-item survey using 5-point Likert scale options, with items grouped by its developers into 5 categories, which have not isolated as discrete factors in previous factor analyses. Categories are: (1) perception of teachers, (2) perception of teaching, (3) academic self-perception, (4) perception of atmosphere, and (5) social self-perception. Kruskall-Wallis tests assessed domain differences across schools, and two-tailed t-tests were used for pairwise comparisons. Significance was set at $p<0.05$ after Bonferroni correction for multiple comparisons.

RESULTS: Complete surveys were collected with the following response rates: 51/55 (93 %) PUGSOM, 97/134 (72 %) PU-RCSI, 221/240 (92 %) CUCMS, and 189/240 (79 %) JHUSOM students. Total JHLES scores were higher at JHUSOM than PU-RCSI, with no differences in other pairwise comparisons. JHLES detected statistically significant differences between schools in 6/7 (86 %) domains, all except "academic climate." Differences did not follow a uniform pattern: JHUSOM and PUGSOM rated "acceptance and safety" higher than CUCMS and PU-RCSI, JHUSOM and CUCMS rated "mentorship" higher than PUGSOM and PU-RCSI, and CUCMS had the highest rating for the "community of peers" domain. Comparing only Malaysian medical schools, a difference was only seen in 1/5 (20 %) DREEM categories (CUCMS rated "perception of teachers" lower than PU-RCSI and PUGSOM) and there were no differences in DREEM total scores. By comparison, JHLES detected significant differences in 5/7 (71 %) domains when only data from Malaysian schools were analyzed. Total JHLES score was highly correlated with the total DREEM score ($\rho=0.80$), and it was more strongly correlated than DREEM to students' global rating of the learning environment ($\rho=0.56$ vs. 0.44).

CONCLUSIONS: JHLES can discriminate between discrete learning environment factors across a range of cultural and educational settings. This results in each school having a unique learning environment profile. Interpretation of these profiles may allow schools to understand how they are currently supporting trainees and to identify areas needing attention.

PROGRESS OR STALEMATE IN ACADEMIC GENDER DISPARITIES? 15 YEAR FOLLOW UP OF THE NATIONAL FACULTY SURVEY Karen Freund^{1,2}; Anita Raj³; Norma Terrin^{1,2}; Samantha Kaplan^{4,5}; Tracy Urech²; Subash Pathak²; Phyllis Carr⁶. ¹Tufts University School of Medicine, Boston, MA; ²Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA; ³University of California, San Diego, San Diego, CA; ⁴Boston University School of Medicine, Boston, MA; ⁵Boston Medical Center, Boston, MA; ⁶Massachusetts General Hospital, Boston, MA. (Tracking ID #1931176)

BACKGROUND: Our prior research found that women compared to men received lower compensation, published fewer articles, and did not advance at the same rate despite similar grant funding productivity. Efforts over the past 20 years have sought to reduce such inequities, but long-term gender differences on these outcomes over the course of the academic career remain unknown. The objective of our current research is to assess gender differences in rank, productivity, compensation and career satisfaction among a national cohort of medical faculty followed from 1995 to 2012.

METHODS: We conducted a follow-up of the 1995 National Faculty Survey cohort, which was drawn from a representative sample of 24 US medical schools, and oversampled generalists as well as underrepresented minority faculty and senior women. We supplemented online survey responses with publicly available data on publications, rank, and leadership on grants. We compared unadjusted median and mean responses on variables between men and women. We adjusted analyses by duration of time in academic career and academic department type (categorized as basic science, medical specialty, surgical specialty or generalist).

RESULTS: We report on 288 men and 301 women. At the time of the follow up survey 62 % of women and 77 % of men reached the rank of full professor ($p < .0002$). Women had fewer median peer-reviewed publications than men (unadjusted median 43 versus 68, $p = .0001$), with a 15 publication deficit after adjustment for duration of the academic career and department type (Wald 95 % confidence interval (CI) 6–25, $p < .005$). The proportion of faculty with funded grants in the prior 2 years was similar between men and women (50 % versus 47 %, $p = .39$). Women had an unadjusted \$26,060 lower mean income compared with men (\$169,190 versus \$195,250, $p < .003$) which was reduced to \$18,830 after adjustment. The difference in a 4 item career satisfaction measure (scale ranged from 4 to 20) was statistically significant, but was a relatively small effect (women, mean = 14.7, standard deviation (SD) = 3.9 versus men, mean = 15.6, SD = 3.5, $p < .0001$). Adjustment for years in academics and department type explained some but not all gender differences.

CONCLUSIONS: Women report similar satisfaction with academic careers, similar grant funding productivity but lower peer-reviewed publication productivity. Women across the course of their careers continue to report lower compensation, and to be less likely to achieve the rank of professor. These findings parallel the status of this group of women compared with their male counterparts in 1995, indicating that rank and compensation gaps remain over the course of the academic career, despite decades to address these disparities.

Variable	Analysis Adjusted for Duration in Academics and Department Type	Women versus Men	95 % CI and p value
Number of Peer-Reviewed Publications	Adjusted mean number of publications	-15	95 % CI -25, -6; $p = .002$
Leadership on Grants	Adjusted OR	.98	95 % CI .69, 1.39; $p = .9$
Achieving Rank of Professor	Adjusted OR	.56	95 % CI .36, .88; $p = .01$
Career Satisfaction	Adjusted parameter estimate	-.81	95 % CI -1.40, -0.22; $p = .008$
Compensation	Adjusted annual compensation	-\$18,830	95 % CI -\$35,647, -\$2,013; $p = .03$

PROJECT BUENA SALUD: EVALUATION OF AN ENHANCED PRIMARY CARE PROGRAM FOR LOW-INCOME HISPANIC PATIENTS WITH TYPE 2 DIABETES Sarah L. Goff^{1,2}; Lorna Murphy^{1,2}; Peter K. Lindenauer²; Paul Visintainer³. ¹Baystate Medical Center/Tufts University School of Medicine, Springfield, MA; ²Baystate Medical Center, Springfield, MA; ³Baystate Medical Center, Springfield, MA. (Tracking ID #1939386)

BACKGROUND: Hispanic patients have a nearly two-fold risk for developing type 2 diabetes (T2DM) compared to their white non-Hispanic peers. Team-based care is increasingly being implemented in the U.S. in an effort to improve management of chronic diseases such as T2DM. This study aimed to assess the impact of enrollment in Buena Salud (BS), a team-based enhanced primary care program, on changes in diabetes control, compliance with target blood pressure and lipid management, and markers of health care utilization for low-income Hispanic patients with T2DM.

METHODS: BS is a pilot intervention initiated in 2011 by Health New England (HNE) a local health insurance company. The program is designed to augment usual primary care by providing individual and group support for chronic disease management for Medicaid Managed Care patients. The bilingual BS team is comprised of 2 nurses, 2 community outreach workers and a social worker. This team offers home visits, interpreter services for specialist visits, diabetes education and other as-needed services for patients enrolled in BS. In this retrospective cohort study, eligible patients were aged 18–64, had been enrolled in BS for at least 15 months, had a least one visit with their primary

care provider in the 12 months before enrollment and has had at least 1 visit in the 15 months following their enrollment date. We reviewed the medical records of all patients enrolled in BS between 8/1/2011 and 2/28/2012. Data extracted included pertinent laboratory results (HbA1c, fasting lipids), blood pressure values, and health care utilization markers (unplanned hospitalizations, emergency room visits). Baseline values were collected for up to 3 years prior to enrollment; 15 months following enrollment was considered the intervention phase. Potential confounders included age, gender, primary spoken language, and comorbid illnesses. The control group consisted of T2DM patients who are patients at the study site health center but were not enrolled in the BS program. The controls were matched (3:1) with intervention patients based on having a visit at the health center in the same month each intervention patient was enrolled. We compared the change in HbA1c, diastolic and systolic blood pressure, LDL, number of hospital admissions and number of emergency room visits between the baseline period and the end of the intervention period among patients in BS and controls.

RESULTS: 67 T2DM patients and 194 controls were included in the study. There were no differences between the groups in any of the variables measured in the baseline period. BS patients had 0–23 contacts (phone and in-person) with the BS team during the intervention (mean = 2.7, sd = 4.0). Over the intervention period BS patients had an increase in HbA1C of 0.33 compared to a decrease in controls of 0.12 ($p = .05$). BS patients had a decrease of -5.59 mm/Hg in mean systolic blood pressure compared to an increase of 2.16 mm/Hg in the controls ($p = .007$). There were no differences in changes in DBP, LDL, the number of hospital admissions or number of emergency room visits between BS patients and controls. The frequency of contact with care team members was not associated with changes in HbA1c, diastolic and systolic blood pressure, LDL, number of hospital admissions and number of emergency room visits.

CONCLUSIONS: Diabetic control worsened slightly for patients enrolled in an enhanced primary care program while blood pressure was modestly improved. This study did not take into account what the nature of the contact between patients and the BS team, which may have a modifying effect on individual patient outcomes. It is also possible that unmeasured factors contributed to the differences observed. Although enrollment in the BS program was not associated with improved control of diabetes it is possible that 15 months is insufficient to see an effect on the outcomes measured and that longer exposure to the intervention may be associated with different outcomes. A randomized controlled trial to compare the effectiveness of usual care compared to enhanced primary care for low-income Hispanic diabetics may better assess the intervention's impact.

PROMOTING POSITIVE CHANGE IN THE RESIDENCY EXPERIENCE THROUGH DISCOVERY OF RESIDENT VALUES

Stephanie A. Rose; Nicholas Jackson; Brittany P. Fenner; Brett Capel; David Rudy. University of Kentucky, Lexington, KY. (Tracking ID #1940299)

BACKGROUND: Residency is a trying experience. This study aims to find constructive means of improving of our Internal Medicine Residency program. Previous attempts to improve our residency program focused on eliminating negative aspects. This study utilized Appreciative Inquiry to identify positive aspects of the current program with the aim to expand upon those ideas and incorporate new suggestions.

METHODS: We conducted appreciative interviews on 27 current Internal Medicine residents. Subjects were asked to answer a series of questions while reflecting on their time as a resident. The questions focused on points such as what he/she expected upon beginning residency, what was his/her high point in residency, what fosters a collaborative and engaged work environment and what actions can be taken to achieve a more engaged staff. The answers were analyzed for thematic categories independently through qualitative methods by three reviewers. Discrepancies were resolved via consensus.

RESULTS: Residents initially sought to improve their medical knowledge, work towards autonomy and gain experience. However, as residents continued in their training they valued the support and respect of their superiors and peers while working as part of a collaborative unit. Residents shifted their focus from academic improvement to fostering better patient relationships and seeing results of the care they provided. When asked what they would do to improve the program, many responded with improving team dedication and communication as well as a more open academic environment.

CONCLUSIONS: While very important, knowledge acquisition may not be what residents' value most in their training. In fact, it was discovered that residents desired

to improve their ability to work as part of a medical team, in both leadership and subordinate roles. Residents feel the program is most effective when support, communication and respect as part of a collaborative environment are held at highest regard. Helping resident accomplish these positive aspirations may help make residency a positive experience.

PROVIDER CULTURAL COMPETENCE AND RACIAL DISPARITY IN DOCTOR-PATIENT RELATIONSHIPS Somnath Saha^{1,2}; Melissa S. Gatchell²; Maya O'Neil²; Jeffrey T. Bates³; Howard S. Gordon⁴; Judith A. Long⁵; Donna L. Washington⁶; Martha Gerrity¹. ¹Portland VA Medical Center, Portland, OR; ²Portland VA Medical Center, Portland, OR; ³Michael E. DeBakey VA Medical Center, Houston, TX; ⁴Jesse Brown VA Medical Center, Chicago, IL; ⁵Philadelphia VA Medical Center, Philadelphia, PA; ⁶Greater Los Angeles VA Healthcare System, Los Angeles, CA. (Tracking ID #1939867)

BACKGROUND: Provider cultural competence (CC) has been widely endorsed as a means to improve the quality of doctor-patient relationships for minority patients and reduce racial disparities in healthcare quality. CC, however, is multidimensional, and few studies have empirically examined which dimensions, if any, are associated with better relationships and greater equity across racial/ethnic groups.

METHODS: We previously developed a self-administered instrument for primary care providers (PCPs), consisting of 6 scales representing different CC dimensions: Perceived Cultural Aptitude, Perceived Cross-Cultural Efficacy, Awareness of Racial Disparities, Valuing Diverse Perspectives, Support for Accommodating Patient Diversity, and Patient-Centered Orientation. In the current study, PCPs at 4 geographically diverse VA Medical Centers completed our CC instrument. We surveyed white and African American patients from participating PCPs' panels, and administered validated instruments to measure patients' global ratings of PCPs, their experience with PCPs' communication and interpersonal style, and their trust in the PCP. We tested associations to determine which CC dimensions were associated with higher ratings of PCPs among minority patients. For CC dimensions positively associated with minority patient ratings, we tested interactions between provider CC and patient race, to determine whether CC dimensions were associated with reduced disparity in outcome measures. We used GEE-based linear regression for all analyses, adjusting for clinic site and patient age, and accounting for clustering of patients within providers.

RESULTS: We recruited 96 PCPs and 998 of their patients. PCPs were predominantly white (49 %) and Asian (27 %), while patients identified mainly as African American (62 %) and white (31 %), reflecting our sampling strategy. The CC dimension most consistently associated with higher minority patient ratings was Valuing Diverse Perspectives. PCPs scoring above the median on this scale received higher ratings from African American patients on communication quality and interpersonal style (Table 1). Higher VDP was not significantly associated with white patients' ratings. We found significant provider VDP-patient race interactions for all outcome measures, indicating that providers placing higher value on diverse patient perspectives received more equal ratings from minority and nonminority patients. For all outcome measures, we observed racial disparities among PCPs with lower VDP scores but no significant disparities among those with higher VDP scores (Table 2).

CONCLUSIONS: Providers rating themselves higher on Valuing Diverse Perspectives—a construct similar to the concept of cultural humility—received higher ratings from African American patients and had less racial disparity in the quality of their relationships with patients. VDP may be an important target, and intermediate outcome measure, for CC interventions aimed at reducing racial disparities in health care quality.

Table 1. Association of Providers' "Valuing Diverse Perspectives" with Patient Ratings of Provider

Outcome	Mean	VDP-Outcome Association (β^*, 95% CI)	
		White Patients	Black Patients
Global Rating of PCP (0-10)	9.05	-0.36 (-.73, .02)	0.26 (-.06, .58)
Communication Quality (1-6)	5.51	-0.14 (-.30, .03)	0.15 (.004, .30)
Interpersonal Style (1-5)	4.67	-0.08 (-.17, .17)	0.12 (.03, .20)
Trust in PCP (1-5)	4.26 (1-5)	-0.10 (-.27, .06)	0.10 (-.04, .24)

* Beta from GEE-based linear regression, adjusting for patient age and clinic site

Table 2. Racial Disparities in Patient Ratings of Provider, by Provider VDP

Outcome	Provider VDP Level	White-Black Disparity (β^*, 95% CI)	
		Low	High
Global Rating of PCP	Low	0.57 (.26, .89)	
	High	-0.02 (-.31, .29)	
Communication Quality	Low	0.16 (.006, .31)	
	High	-0.07 (-.21, .07)	
Interpersonal Style	Low	0.09 (.002, .18)	
	High	-0.04 (-.11, .03)	
Trust in PCP	Low	0.23 (.09, .37)	
	High	0.04 (-.09, .16)	

* Beta from GEE-based linear regression, adjusting for patient age and clinic site

PROVIDER RESPONSE TO ONLINE SELF-MANAGEMENT SUPPORT FOR OBESITY INTEGRATED WITH PRIMARY CARE Kathleen M. McTigue^{1,2}; Molly B. Conroy^{1,2}; Laurey R. Simkin-Silverman²; Dana L. Tudorascu¹; Rachel Hess^{1,2}; Gary Fischer¹; Cindy L. Bryce^{3,1}. ¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA; ³University of Pittsburgh, Pittsburgh, PA. (Tracking ID #1937944)

BACKGROUND: Less than half of obese US adults report that their physician has advised them to lose weight and numerous barriers including time constraints, cost and limited physician training make lifestyle counseling in the clinical setting difficult. Health information technology is considered a promising avenue for addressing gaps in care and providing patient-centered, yet affordable, health care services. For widespread implementation, such tools must be acceptable to providers and smoothly integrated with care.

METHODS: We evaluated physician response to a year-long intervention providing self-management support for weight loss to 373 obese primary care patients. Physicians referred patients to the structured behavioral online program. They then received feedback from each participant's online lifestyle coach over the course of the year. We surveyed physicians at the 6 participating primary care practices representing a range of practice settings (e.g., academic, private, urban, rural) regarding their responses to the program. Each provider was emailed survey links on multiple occasions, and paper surveys were distributed at practice meetings and resident seminars. Cross-sectional analyses examined sample demographics, compared attitudes towards obesity counseling among adopting and non-adopting providers, and quantified impressions of how smoothly the referral model of obesity treatment was integrated with clinical workflow.

RESULTS: Of 185 providers, 67 (36 %) completed surveys; 99 % were physicians, 46 % were female, 5 % were Hispanic and 2 % were African American. Among respondents, 49 (73 %) had referred patients to the program. When we compared referring providers ("adopters") with non-referring providers ("non-adopters"), the two groups did not differ in sex or race/ethnicity, but varied in training status with 71 % of the non-referring providers and 12 % of referring providers being resident physicians ($p<0.001$). Among adopters, most agreed that the referral approach to enrollment (94 %) and the process for providing 1-year follow-up reports (80 %) integrated smoothly with their normal workflow. Compared with adopters, non-adopters were more likely to report preferring counseling on healthy eating and exercise patterns themselves rather than referring for counseling (29 % versus 8%; $p=0.040$). Non-adopters reported sufficient time during clinic visits to counsel patients adequately on diet, physical activity and obesity more often than did adopters (29 % versus 8%; $p=0.026$). Non-adopters more often reported that their patients were generally not interested in using internet-based lifestyle counseling (47 % versus 22%; $p=0.007$), were likely to have minimal computer skills (76 % versus 35%; $p=<0.001$), or were likely to lack internet access (64 % versus 32%; $p=0.04$). Both adopters and non-adopters noted that their patients would benefit from advice to lose weight through lifestyle change. However, 20 % of all respondents felt that their patients were generally not interested in receiving counseling for diet, physical activity and weight loss and 20 % reported that obesity should be managed outside the clinical setting. Most respondents agreed that they find it useful to refer patients to community counseling resources for promoting healthy lifestyles (42 % somewhat agreed and 39 % strongly agreed).

CONCLUSIONS: A referral model is able to smoothly integrate online self-management support into routine primary care practice. The adoption of online self-management support tools may be most likely among PCPs with limited available time for counseling, those without a strong preference for personally delivering preventive behavioral counseling, and those who have completed residency training. PCP perception that their patients lack internet access, skills, or interest can inhibit adoption of online counseling tools.

PROVIDERS' PERSPECTIVES ON ESSENTIAL FUNCTIONS FOR CARE MANAGEMENT IN THE TREATMENT OF HYPERTENSION: THE P.A.R.T.N.E.R. FRAMEWORK Tanvir Hussain^{1,2}, Allyssa Allen^{4,2}, Jennifer Halbert², Cheryl A. Anderson³, Romsai T. Boonyasai^{1,2}, Lisa A. Cooper^{1,2}. ¹Johns Hopkins University School of Medicine, Baltimore, MD; ²Johns Hopkins Center to Eliminate Cardiovascular Health Disparities, Baltimore, MD; ³University of California, San Diego School of Medicine, San Diego, CA; ⁴University of Maryland, Baltimore County, Baltimore, MD. (Tracking ID #1939802)

BACKGROUND: The provision of comprehensive services for chronic illness care in primary care is limited by a lack of physician time and tools. Care management (CM) has become a popular strategy to address this challenge. CM typically involves non-physician care managers working with patients between encounters with primary

care providers (PCPs) in order to improve clinical care, enhance care coordination, and reduce health care utilization. To our knowledge, however, PCPs' perspectives on CM activities that will improve patient care have not been examined, jeopardizing the potential for successful collaboration between care managers and PCPs. We aim to identify functions of CM most valuable to PCPs in hypertension treatment.

METHODS: Six focus groups were conducted. Thirty-nine of the 47 PCPs from six community-based clinics within a large physician group practice in the greater Baltimore metropolitan area participated. PCPs were racially diverse (51 % White, 23 % Black, and 21 % Asian), were in practice on average 17 years, and 69 % worked in an underserved site. Questions and prompts about hypertension treatment and CM in primary care were standardized and pilot tested. Focus groups were audio recorded and transcribed verbatim. Recurring themes were identified by: reviewing the transcripts from three focus groups; reviewing the coding scheme with the research team before analysis; and periodically refining the scheme as new themes emerged during analysis until thematic saturation was reached. Initially, themes for CM included: existing hypertension care support available to PCPs, essential functions for CM, and challenges to CM success. To further refine the breadth of comments under essential CM functions, a second stage of coding was performed independently by two physician-researchers.

RESULTS: We identified 74 statements that fell within seven domains of essential CM functions. Inter-rater agreement on coding of essential functions was 92 %. The most commonly cited functions for care management, each 20 % of total annotations, belonged to the domains of "providing education" and "identifying and resolving barriers to adherence." Using these data, we created the P.A.R.T.N.E.R. framework, which reflects the activities providers find essential to effective care management: Partner with the patient, providers, and the community; Assess response to the treatment plan & Arrange follow-up care; Resolve barriers to adherence & Recalibrate the treatment plan; Track patient progress; Navigate the health care system with the patient; Educate the patient & Engage the patient in self-management; Relay information between the patient and/or provider. The framework also lists a "scope of activities," or a range of possible tasks satisfying each function. Based on PCPs' perspectives, all P.A.R.T.N.E.R. functions should be represented in an optimal care management program, though the specific tasks to fulfill each function may vary across clinical settings.

CONCLUSIONS: The P.A.R.T.N.E.R. framework is the first to offer a comprehensive list of CM functions that may be useful in clinical practice based on primary data collection from PCPs. This perspective has not yet been documented, though PCP buy-in is essential to the success of team-based care models. Future research should examine the reliability and validity of this framework in various settings and for diverse patient populations affected by chronic diseases.

PROVISION OF FAMILY PLANNING TO WOMEN WITH CARDIOVASCULAR RISK FACTORS Shivani M. Reddy^{1,2}; Ambili Ramachandran¹; Howard Cabral⁴; Lewis Kazis³. ¹Boston University School of Medicine, Boston, MA; ²VABoston Healthcare, Boston, MA; ³Boston University School of Public Health, Boston, MA; ⁴Boston University School of Public Health, Boston, MA. (Tracking ID #1936950)

BACKGROUND: Cardiovascular risk factors (CVRFs) in reproductive-aged women can lead to pregnancy complications and fetal anomalies. Family planning in this population is not well studied.

METHODS: We performed a cross-sectional analysis using data from the National Ambulatory Medical Care Survey for the years 2009–2010. The study sample consisted of visits by reproductive-aged women with CVRFs of diabetes, hypertension, hyperlipidemia, obesity, or tobacco use. The comparison group was visits with no chronic disease. Primary outcome measure was family planning action, defined as counseling, medication, or procedure.

RESULTS: Among 223,407,070 ambulatory visits by non-pregnant reproductive-aged women, 30.8 % were associated with at least one CVRF, and 17.2 % had at least one family planning action. There was no increased frequency of family planning for visits by women with CVRFs. In the multivariable model, the odds ratio of receiving family planning with presence of a CVRF was 1.2 (95 % CI 0.9–1.5). Visits for preventive care (OR 2.3, 95 % CI 1.8–3.1), as well as gynecologic and sexual health care (OR 2.6, 95 % CI 1.9–3.7), were significantly associated with increased odds of family planning.

CONCLUSIONS: There are low rates of family planning in visits by reproductive-aged women overall, with no significant difference for visits by women with CVRFs. Comprehensive preventive visits in primary care may especially benefit women of reproductive age with CVRFs, reducing risk of poor pregnancy outcomes.

PUBLICATION RATES OF MEDICAL EDUCATION ABSTRACTS PRESENTED AT THE SOCIETY OF GENERAL INTERNAL MEDICINE 2009 ANNUAL MEETING Adam Sawatsky; Thomas J. Beckman; Amy T. Wang. Mayo Clinic, Rochester, MN. (Tracking ID #1939341)

BACKGROUND: A recent meta-analysis revealed that 44.5 % of abstracts presented at national meetings were subsequently published in peer-reviewed journals. Two studies have revealed lower publication rates for medical education research abstracts (33 % and 35 %). Previous research has shown that quality of medical education research is a predictor of manuscript acceptance. However, it is unknown whether the quality of medical education abstracts is associated with subsequent publication in peer-reviewed journals. Our goals were to determine: 1) journal publication rates of medical education abstracts presented at a Society of General Internal Medicine (SGIM) Annual Meeting, 2) if abstract quality was associated with subsequent publication, and 3) if there were differences in publication rates and quality of medical education abstracts submitted as scientific abstracts versus ‘innovations in medical education’ (IME).

METHODS: This was a retrospective study of abstracts accepted to the SGIM 2009 Annual Meeting. The 2009 meeting was chosen to allow sufficient time for abstracts to be published. We included all scientific abstracts that described medical education research and all IME abstracts. To identify subsequent publication in a peer-reviewed journal, we searched PubMed, ISI Web of Knowledge and Google Scholar for full-text publications through December 2013 using a combination of first, second, and last authors’ names, as well as keywords from the title. The title, authors, methodology, and results of the published article were compared to the original abstract to confirm matches. We abstracted data on the type of research (quantitative versus qualitative), study population (undergraduate [UME], graduate [GME] or continuing medical education [CME]), submission category, and time to publication. To identify study quality for the abstracts using quantitative methods, we used the Medical Education Research Study Quality Instrument (MERSQI), a previously validated instrument with strong content, criterion, and predictive validity evidence. The MERSQI contains 10 items (overall score range 5–18) within 6 domains of study quality: study design, sampling, data type, validity of assessments, data analysis, and outcomes. Three authors rated 5 abstracts independently, resolved differences by consensus, and reached satisfactory agreement. One author scored the remaining abstracts. We utilized the Chi-squared test to calculate odds ratios to determine if abstract MERSQI scores were associated with subsequent publication; a MERSQI score of >10 was used to define high quality research. We utilized the Fisher’s exact test to compare publication rates and two-sample t-tests to compare MERSQI scores of scientific versus IME abstracts. The threshold for statistical significance was set at a $p<0.05$. This study was deemed exempt by the Mayo Clinic Institutional Review Board.

RESULTS: Of 651 scientific abstracts reviewed, 143 met criteria for medical education scholarship. Overall, 62 (43 %) medical education abstracts presented at SGIM were subsequently published in indexed medical journals. The mean time to publication was 21.5 months. The majority of abstracts were quantitative (119, 83 %) and involved GME (75, 52 %) and UME (43, 30 %), with only a minority involving CME (7, 5 %) or mixed populations (18, 13 %). The average MERSQI score for all medical education abstracts was 9.2 (SD, 1.76; range 5–14). Higher quality medical education abstracts ($\text{MERSQI} \geq 10$) were more likely to be published than lower quality abstracts ($\text{MERSQI} < 10$; OR 3.18; 95 % CI, 1.47–6.89; $p=0.003$). Scientific abstracts, as compared to IME abstracts, had higher publication rates (53 % v. 33 %, $p=0.02$) and higher MERSQI scores (9.8 v. 8.4, $p<0.001$). Furthermore, scientific abstracts scored significantly higher than IME abstracts in the following MERSQI domains: sampling (number of institutions studied and response rate), validity of evaluation instrument (content and internal structure), and data analysis (appropriateness and complexity of analysis).

CONCLUSIONS: The journal publication rate of medical education abstracts presented at the SGIM 2009 Annual Meeting was similar to previously demonstrated publication rates for biomedical research abstracts, but was higher than publication rates of medical education abstracts presented at other scientific meetings. Furthermore, this may be the first study to demonstrate an association between a validated measure of abstract quality and subsequent journal publication. These findings suggest that attention to measures of quality, such as those found in the MERSQI, may optimize the likelihood that medical education abstracts will be published in peer-reviewed journals. These findings also indicate that education innovation projects might be improved by utilizing study designs that incorporate multiple institutions, utilize validated evaluation instruments, and apply appropriate statistical analyses.

PULMONARY HYPERTENSION PREVALENCE IN AN AFRICAN-AMERICAN END-STAGE RENAL DISEASE POPULATION ON HEMODIALYSIS Bronwyn L. Small¹; Camelia Arsene²; Irfan Omar². ¹Henry Ford Hospital, Detroit, MI; ²Sinai-Grace Hospital, Detroit Medical Center, Detroit, MI. (Tracking ID #1939103)

BACKGROUND: The development of peritoneal and hemodialysis (HD) have changed kidney failure from a fatal disease to a treatable condition. The overall five-year survival, however, remains relatively low: 39 % in African-Americans compared to 32 % in Caucasians. Cardiac and cardiovascular causes of death continue to be the most common causes of mortality in the prevalent end-stage renal disease (ESRD) population, co-morbid conditions including Pulmonary Hypertension (PH), threaten to further shorten the lifespan of ESRD patients. Recent investigations have shown a high prevalence of PH in HD patients from 26 to 52 %. It has also been found that the presence of PH has led to significantly lower survival rates as compared to those without PH; in addition, PH has been found to be an independent predictor of all-cause mortality in ESRD patients.

METHODS: A prevalence study was undertaken; recruiting patients with ESRD who were undergoing treatment with HD for >3 months, at a teaching hospital or outpatient HD clinic in Detroit, MI. Inclusion in the study required the completion of a short demographics questionnaire, physical examination and permission for researchers to access hospital/clinic records for laboratory values, medical history and imaging results. The questionnaire documented demographics, medical history and presence or absence of various risk factors for PH. A search was conducted within the patients’ medical record for transthoracic echocardiogram (TTE) results within the past year, in addition to recent laboratory values.

RESULTS: Of the 99 patients enrolled in the study, 46 of these patients were found to have a TTE completed within the last year and were included in the study. All participants in the study were African-American. Forty-one patients (89 %) were found to have an $\text{RVSP} \geq 25$ mmHg, indicating the presence of PH based on TTE findings. The PH patients were also found to have a high prevalence of HTN (97.6 %), CAD (61 %), CHF (58.5 %), COPD/ Asthma (34.2 %). No significant correlations were found between RVSP and Ejection Fraction, Urea reduction ratio, PTH or Calcium-Phosphate product.

CONCLUSIONS: PH appears to be highly prevalent in the ESRD population on HD, particularly in this African-American community. There are likely multiple etiologies of PH in these individuals due to the high incidence of comorbid heart and lung diseases. Further investigations should be completed to determine if the early diagnosis and treatment of PH in these individuals, could help improve survival rates in the ESRD population.

QUALITY OF HYPERTENSION CARE IN A STUDENT-RUN FREE CLINIC: A PILOT STUDY Neil Pathak; Peter Ellis; Rachel J. Perry; Kristina Talbert-Slagle. Yale University, New Haven, CT. (Tracking ID #1928117)

BACKGROUND: Student-run free clinics have become an important source of medical care to underserved populations. Thus, it is critical to determine the quality of medical care delivered in such settings. Few studies have evaluated quality of care in student-run free clinics that serve a predominantly Hispanic population. In this study, we assessed the quality of hypertension care offered by a weekly student-run free clinic, supervised by clinical faculty, that provides care to a mainly Hispanic underserved population.

METHODS: An IRB approved retrospective chart review was performed on all patients who were seen at the clinic between January 2012 and January 2013. Inclusion criteria were that the patient must have been seen for at least two visits following the visit at which hypertension was first recorded. Demographic factors,

body mass index (BMI), blood pressure measurements across visits, prescribed medications, alcohol and tobacco use, and comorbidities were collected. Healthy People 2020 and the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 7) were used as national standards to assess the quality of hypertension care. Fisher's exact test was used to determine associations between hypertension control and each of the following variables: stage of hypertension; comorbidities; obesity; alcohol use; tobacco use.

RESULTS: Twenty patients (9 females, 11 males) met the inclusion criteria and were included in our pilot study. 18 (90 %) patients were Hispanic, mean age was 46.9 (SD=13.4), and mean BMI was 27.8 (SD=3.3). 17 (85 %) had Stage 1 hypertension and 3 (15 %) had Stage 2 hypertension at the visit when hypertension was first recorded. Hydrochlorothiazide was the most commonly prescribed medication (65 %); calcium channel blockers (5 %) and angiotensin-converting enzyme inhibitors (5 %) were used infrequently. The remaining 25 % of patients were solely given lifestyle modification training. It was found that 14 (70 %) patients achieved goal blood pressure (as defined by JNC 7) at the most recent visit. 3 (15 %) patients had dyslipidemia and 1 patient (5 %) had diabetes. 6 (30 %) patients reported using both alcohol and tobacco, 3 (15 %) reported using only tobacco, and 3 (15 %) reported using only alcohol. We found an association between uncontrolled hypertension at the most recent visit and each of the following variables: Stage 2 hypertension diagnosis; simultaneous alcohol and tobacco use ($p<0.05$). There was no association between hypertension control and the following variables: sole alcohol use; sole tobacco use; comorbidities; obesity ($p>0.05$).

CONCLUSIONS: The percentage of patients in this pilot study who achieved goal blood pressure (70 %) met objectives specified by Healthy People 2020 (61.2 %). Prescribed therapies chosen to treat hypertension met recommended guidelines defined by JNC 7. Simultaneous alcohol and tobacco use as well as initial Stage 2 hypertension diagnosis was found to be linked to uncontrolled hypertension; it therefore may be advisable for medical students to pay more attention to these patients, especially with regard to using multi-drug combinations. This pilot study suggests that a student-run free clinic is able to provide the appropriate pharmacotherapy and/or lifestyle modification training to achieve goal blood pressure in a middle aged, uninsured Hispanic population. Such initiatives may be a potential solution to treating hypertension among some patients in underserved areas.

QUALITY OF LIFE AS AN INDEPENDENT MEASURE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS Aliya Sarmanova^{1,2}; Saule Abisheva¹; Gulvira Magzumova²; Rysgul Aytzhanova³. ¹Astana Medical University, Astana, Kazakhstan; ²No2 Municipal Hospital, Astana, Kazakhstan; ³The Republican Diagnostic Center, Astana, Kazakhstan. (Tracking ID #1937303)

BACKGROUND: Health-related quality of life (HRQoL) represents patient's overall perception of the illness, symptoms severity and treatment impact on physical, emotional, and social functions and became an important complementary source of information in patients with Systemic Lupus Erythematosus (SLE). Older age, disease duration and higher scores of activity and damage seems to greatly influence the reduction of HRQoL, but according to many scientific researches, this data is still controversial. The objective of our study was investigation of the HRQoL and its relationship with clinical and demographic data in patients with SLE.

METHODS: in our study we included consecutive patients, fulfilling the 1997 ACR Classification Criteria for SLE. Quality of life was evaluated using patient self-assessment questionnaire of Medical Outcomes Survey Short Form-36 (SF-36, version 2). Disease activity was measured using Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), and organ damage assessed by the Systemic Lupus International Coordinating Clinics/American College of Rheumatology Damage Index (SLICC/ACR-DI). Associations between eight QoL domains and age, disease duration, disease activity, and damage were explored using Spearman's correlation coefficients (r_s).

RESULTS: The study group comprised 30 lupus patients. All of them were women, 86.7 % Asians and 23.3 % Caucasians with mean age of 32.67 years (95 % CI 28.26;37.07) and mean duration of the disease 6.87 years (95 % CI 4.11;9.63). Mean SLEDAI score was 14.57 points (SD±8.26). Mean SDI was 1.03 with damage in 53.3 %. There were correlation between SDI score and disease duration ($r_s=0.567$, $p=0.001$) and SLEDAI score ($r_s=0.469$, $p=0.009$). The clinical characteristics of the patients are shown in Table 1. Age and disease duration did not show any significant relationship with the HRQOL scores in any of the domains. Similarly, there were no statistically significant correlations between the scores of the SF-36 domains and scores of SLEDAI and SLICC/ACR-DI (Table 2).

CONCLUSIONS: From obtained results we concluded that there is no clinically important associations between the all domains of the SF-36 and clinical or

demographic variables. This suggests that disease activity, accumulated damage, and HRQoL remain an important independent outcome measures in the assessment of health status and full impact of the disease on social functioning. It should be recommended for evaluation in SLE patients.

Clinical and laboratory characteristics of the patients ($n=30$)

QUANTIFYING THE CONTRIBUTION OF DEFENSIVE MEDICINE TO PRIMARY CARE COSTS Andrei Brateanu; Sarah Schramm; Bo Hu; Kristen Boyer; Kelly Nottingham; Glen Taksler; Stacey E. Jolly; Kenneth Goodman; Anita D. Misra-Hebert; Nirav Vakharia; Aaron Hamilton; Robert Bales; Mahesh Manne; Abhishek Deshpande; Amanda Lathia; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Tracking ID #1918689)

BACKGROUND: Defensive medicine is one contributor to waste in health care. Studies that measure its cost have produced conflicting results. The goal of this study was to directly measure the proportion of primary care costs attributable to defensive medicine.

METHODS: We enrolled primary care physicians (PCP) from 4 outpatient practices in a 6-week prospective study. PCPs completed attitude surveys with information on whether they had been sued, knew anyone who had been sued, and how much they feared being sued. In addition, on 3 distinct days, PCPs were asked to rate each order placed the day before on the extent to which it represented defensive medicine, using a 5-point scale from 0 (not at all defensive) to 4 (entirely defensive). Two scores were calculated: the order defensiveness score for each order (the defensiveness/4) and the physician defensive score (the mean of the defensiveness scores for all orders). Costs were assigned based on Medicare reimbursement rates. Each order was assigned a weighted defensiveness cost by multiplying the cost of that order by its defensiveness score. The proportion of total cost attributable to defensive medicine was defined as the ratio of the weighted cost of defensive orders to the total cost of all orders. A logistic regression model with random effects was used to examine physician and patient factors associated with the defensive medicine score. The model was adjusted for demographic variables, including gender, years in practice, previous malpractice litigation (yes/no), fear of future malpractice litigation, US vs. foreign medical school, and academic vs. community hospital training.

RESULTS: Of 50 eligible PCPs, 23 agreed to participate; 21/23 (91.3 %) returned the surveys and rated 1234 individual orders on 347 patients. Physicians wrote an average of 3.6 ± 1.0 orders/patient/visit with an associated cost of $\$72.60 \pm 18.5$ per order. Of the 1,234 orders, 89.8 % were reported as not defensive at all, 9.5 % were reported as somewhat defensive (1–2 on the scale), and 0.8 % were reported as mostly defensive (3–4 on the scale). Across physicians, the median physician defensive score was 0.018 (IQR=[0.008, 0.049]) and the proportion of total costs attributable to defensive medicine was 3.1 % (IQR=[0.5 %, 7.2 %]). PCPs with total defensive scores above compared with those below the median had a higher proportion of total costs attributable to defensive medicine (6.1 %, IQR=[2.4 %, 9.8 %] vs. 1.5 %, IQR=[0.1 %, 2 %], $P=0.004$), but similar number of orders (3.38 ± 0.86 vs. 3.74 ± 1.07 , $P=0.41$) and total costs ($\$239.9 \pm 93.2$ vs. $\$243.9 \pm 61.0$, $P=0.91$), per patient per visit. Physicians were more likely to have high defensive scores if trained in community hospitals vs. academic centers (AOR, 4.29; 95 % CI, 1.55 to 11.86; $P=0.01$). Gender, experience, previous malpractice litigations and fear of being sued were not significantly associated with defensiveness.

CONCLUSIONS: This study provides a new method to directly quantify the cost of defensive medicine. Defensive medicine appears to have minimal impact on primary care costs.

QUESTIONING THE VALIDITY OF CONSIDERING LEFT ATRIAL ENLARGEMENT ON EKG AS AN ABNORMAL FINDING IN YOUNG ATHLETES Tatvam T. Choksi¹; Martin O'Riordan². ¹Mercy Catholic Medical Center, Darby, PA; ²Mercy Catholic Medical Center, Darby, PA. (Tracking ID #1938664)

BACKGROUND: The current ‘Seattle Criteria’ for electrocardiographic interpretation in athletes consider left atrial enlargement as an abnormal finding that requires further investigation. Others have looked into the criteria by involving predominantly Caucasian athletes and it showed around 13 % prevalence of abnormal EKG findings, but very few of them had abnormal 2D-Echo. Given the prevalence of Hypertrophic Obstructive Cardiomyopathy [HOCM] is more in African American than Caucasians; we performed a study on African American athletes of urban Philadelphia.

METHODS: In 2013, we studied a cohort of 55 young athletes aged between 12 and 25 years. All athletes were screened with 12-lead EKG. Electrocardiographic interpretation was based on 2012–13 Seattle criteria for athletes and those with abnormal findings per the criteria underwent 2D-Echo for further evaluation.

RESULTS: Of 55 athletes, 100 % were African American and majority [80 %] were males. None [0 %] reported family history of sudden cardiac death or any cardiovascular symptoms. Athletes were trained in different sporting modalities and trained for an average of 17 h per week. Out of 55 athletes, 7 [12.72 %] had left atrial enlargement and met abnormal EKG findings as per the Seattle Criteria. These athletes underwent echocardiographic evaluation and none [0 %] of them had any structural or functional abnormalities on 2D-Echo.

CONCLUSIONS: Our study showed expected prevalence of left atrial enlargement on EKG in athletes and it did not show any echocardiographic abnormalities. Isolated left atrial enlargement on EKG in young athletes is a common finding that hasn’t shown to predict underlying cardiomyopathies and may be just reflective of benign physiologic adaptation in athletes. Exclusion of left atrial enlargement as an abnormal finding in those without abnormal physical exam findings or family history of sudden cardiac death may increase the cost effectiveness of the pre-participation screening programs. Other study involving Caucasian athletes has highlighted the same point. Given this, it would be reasonable to say that this observation can be applied to young athletes in general and it would be practical to revise the criteria, though our sample size was small.

RACIAL AND ETHNIC DIFFERENCES IN SCREENING FOR DIABETES MELLITUS: NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY 2005–2012 Meghan M. Kiefer^{1,2}; Julie B. Silverman^{1,2}; Karin M. Nelson^{1,2}. ¹University of Washington School of Medicine, Seattle, WA; ²VA Puget Sound Healthcare System, Seattle, WA. (Tracking ID #1936714)

BACKGROUND: Nearly 1 in 5 persons with diabetes in the US is undiagnosed, despite the importance of early detection and treatment. Racial disparities in the prevalence and morbidity of diabetes exist; African-Americans are more likely to have worse glycemic control, higher rates of complications, and higher diabetes-associated mortality. Often,

patients with diabetes already have complications from their disease at time of diagnosis. Screening is key to detection of diabetes; however, recent population-based estimates of screening prevalence in the US have not been established.

METHODS: We analyzed the 2006–2012 National Health and Nutrition Examination Survey (NHANES) data. Using a nationally representative, cross-sectional sample of non-pregnant US adults, we estimated diabetes screening prevalence according to age, race/ethnicity, and appropriateness of screening status. We then performed multivariate logistic regression, examining the association between race/ethnicity and screening self-report when adjusted for socio-demographic factors. Statistical analysis was conducted using Stata survey procedures to account for the complex sampling design of NHANES.

RESULTS: Forty-three percent of all US non-pregnant adults reported being screened for diabetes in the preceding 3 years. Amongst those who should be screened per American Diabetes Association (ADA) guidelines, only 49.6 % reported screening (95 % CI, 48.2–51.0.), with only 42.0 % of high-risk adults 45 and younger reporting screening. After adjusting for age, gender, sex, BMI, self-reported hypertension, dyslipidemia, physical inactivity, insurance status, poor healthcare access, and survey cycle, Hispanics were more likely to report screening than whites (OR 1.82, $p<0.001$) as were non-Hispanic blacks (OR 1.34, $p=0.100$). Among those who reported being screened, the proportion considered appropriate were 87.9 % of non-Hispanic blacks, 88.3 % of whites, 80.4 % of Hispanics, and only 70.0 % of those of other racial/ethnic backgrounds who reported screening were considered appropriate.

CONCLUSIONS: In a nationally representative sample of US adults, fewer than half of those who meet ADA screening guidelines are being screened for diabetes. After adjusting for multiple factors, non-white populations in the US are more likely to report diabetes screening in the preceding 3 years. This suggests that screening inequality is unlikely to account for racial/ethnic disparities in diabetes outcomes. Further efforts to increase appropriate screening, while also reducing unnecessary screening, are needed.

RACIAL AND ETHNIC DISPARITIES IN CONTRACEPTIVE USE AMONG SEXUALLY-ACTIVE WOMEN WHO DESIRE NO MORE CHILDREN Cynthia D. Grady¹; Christine Dehlendorf²; E. Bimla Schwarz³; Sonya Borrero^{3,4}.

¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²UCSF School of Medicine, San Francisco, CA; ³University of Pittsburgh, Pittsburgh, PA; ⁴VA Center for Health Equity Research and Promotion, Pittsburgh, PA. (Tracking ID #1934078)

BACKGROUND: There are significant racial/ethnic disparities in contraceptive use among US women. Whether disparities persist among women who explicitly state that they are finished with childbearing is unknown. This analysis examined the relationship between race/ethnicity and contraceptive use among a cohort of women who stated that they do not desire any (more) children.

METHODS: We conducted an analysis of nationally-representative, cross-sectional data from the 2006–2010 National Survey of Family Growth. Our sample consisted of women aged 15–44 who had sexual intercourse with a man in the past 3 months, had no history of infertility, were not currently pregnant, and reported that they did not want (more) children. Our key independent variable was self-reported race/ethnicity. Outcomes included use of any contraceptive method at last heterosexual intercourse and type of contraceptive method used among women who used a method. Methods were categorized as highly effective (male or female sterilization, IUD, implant), moderately effective (injection, pill, patch, ring), or least effective (barrier and behavioral methods). Covariates included socio-demographic characteristics (age, religion, marital status, income, education, insurance), reproductive characteristics (parity, prior unintended pregnancy), and an indicator of healthcare utilization (receipt of any reproductive health services in the past 12 months). We conducted multivariable logistic regression to assess the independent effect of race/ethnicity on our outcomes after adjusting for all covariates.

RESULTS: Our cohort included 2,913 women: 66.1 % were white, 12.3 % black, and 16.3 % Hispanic. The vast majority of women (91.2 %) used a contraceptive method at last intercourse, although this varied by race/ethnicity with 93.3 % of whites reporting use of any method, compared to 84.7 % of blacks and 90.6 % of Latinas ($p<0.01$). In adjusted analysis, compared to whites, blacks were significantly less likely to use any contraception (OR:0.43; 95 % CI:0.25–0.72), while there was no significant association for Latinas (OR:0.93; 95 % CI:0.52–1.67). With regard to type of method used at last intercourse, 59.3 % of women used a highly-effective method of contraception,

18.8 % used a moderately-effective method, and 21.9 % used a least-effective method. Type of method varied by race/ethnicity in bivariate analysis with 80.8 % of whites, 75.2 % of blacks, and 73.4 % of Latinas women using a highly- or moderately-effective method ($p<0.01$). In the adjusted model, when compared to white women, black and Hispanic women trended toward a lower likelihood of using a highly- or moderately-effective method versus a least-effective method, although these associations did not reach statistical significance (OR:0.70; 95 % CI:0.46-1.05 and OR:0.76; 95 % CI:0.52-1.12, respectively).

CONCLUSIONS: Among a nationally-representative cohort of women at risk for unintended pregnancy who report that they do not desire (more) children, black women were significantly less likely than white women to use any contraception at last intercourse. Future research should explore other factors, beyond socioeconomic status and differential healthcare utilization, that may contribute to observed racial disparities in contraceptive use, including cultural norms, contraceptive knowledge, and patient-provider relationships.

RACIAL DISPARITIES IN GASTROINTESTINAL STROMAL TUMOR CLINICOPATHOLOGIC FEATURES AND SURVIVAL OUTCOMES Raji Shameem¹; Muhammad S. Hamid²; Niket Sonpal¹; Arvind Randhawa³; Nakul Singhal¹; Kevin Sullivan³. ¹Lenox Hill Hospital, Dix Hills, NY; ²Detroit Medical Center, Detroit, MI; ³Lenox Hill Hospital, New York, NY. (Tracking ID #1940057)

BACKGROUND: Gastrointestinal Stromal Tumors (GIST) are the most common mesenchymal malignancies of the gastrointestinal tract. In 2002, the tyrosine kinase inhibitor Imatinib was approved as a treatment for unresectable and metastatic GIST. Imatinib has been shown to improve survival in certain patients. Currently little is known of the clinicopathologic features and survival outcomes for different racial groups prior to and after the introduction of Imatinib.

METHODS: Patient information from 1988 to 2008, were extracted using Surveillance, Epidemiology, and End Results (SEER) database. Clinicopathologic features that were classified included age at diagnosis (<45 years, 45–60 years, 60–75 years, >75 years), tumor size (<5 cm, 5–10 cm, >10 cm) anatomic location (esophagus, stomach, small intestine, large intestine, rectum), radiation, and surgical intervention. A descriptive analysis and age-adjusted survival rates were calculated using univariate Cox-regression hazard models for non-Hispanic whites (NHW), Hispanics, Blacks, and Asian/ Pacific Islanders (API) races using SPSS 21.0. Difference amongst proportions and groups were calculated using Z-scores and Kurskal-Wallis test respectively.

RESULTS: A total of 4,386 patients were included in our study. Regarding tumor location, compared to NHW, gastric tumors were significantly more common in Blacks (77.8 % vs 52.1 %; $p=0$). Gastric tumors were also more common in Hispanics (53.6 %) and API (56.5 %), however no significant difference was seen ($p>0.05$). For Blacks, Hispanics and API, the most common non-gastric location was the small intestine ($p=0.01$). GIST was significantly more common in female Blacks (51.9 % vs 45.2 %; $P=0.004$), whereas it was more common in males in all other groups. Age at diagnosis occurred earlier in Hispanics (57 ± 15.75 years) with the greatest proportion (33.3 %), presenting in the 45–60 age group, compared to 60–75 in all the other races. For all races, age greater than 60 year was associated with decreased survival ($P<0.05$), while cancer directed surgical intervention was associated with increased survival ($P<0.05$). For API and NHW, radiation therapy (HR: 2.1 and HR: 2.1; $P<0.05$) and tumor size >10 cm (HR: 3.72 and HR: 2.07, $P<0.05$) respectively, were associated with worse outcomes. Regarding tumor location in NHW, decrease survival was observed in tumors presenting in the splenic flexures (HR: 4.588, $p<0.05$). In the post-Imatinib era (after 2002), increased survival was seen in NHW (HR: 0.51, $P=0$), Blacks (HR: 0.56, $P<0.05$), and API (HR: 0.64, $P<0.05$), however no significant difference was seen in Hispanics (HR: 0.80, $P=0.23$).

CONCLUSIONS: To our knowledge this is the most up to date SEER analysis of the clinicopathologic features and survival outcomes of GIST tumors among different racial groups. Previous literature has commented that the most common anatomic location is the stomach. Our results support the regularity of gastric GIST but also demonstrate that it is seen more commonly in Blacks compared to NHW. Also Blacks, unlike other races were seen to have significantly higher number of females diagnosed with GIST. Our study was the first to analyze the SEER database for survival outcomes of large tumors (>10 cm), which were associated with poor prognosis. Age greater than 60 years also showed decreased survival. Interestingly,

tumors located at the splenic flexures were associated with the worst prognosis in NHW. The introduction of Imatinib as a treatment for GIST has shown impressive results in improving overall survival in patients, which was seen in our analysis for NHW, Blacks, and API. However, Hispanics did not show improved outcomes in the post-Imatinib era despite having the earliest age at diagnosis. This suggests that Hispanics have more aggressive GIST compared to other races.

RACIAL DISPARITIES IN THE PRIMARY CARE OF PATIENTS WITH CHRONIC KIDNEY DISEASE (CKD) Raquel Greer¹; Lisa A. Cooper¹; Yea-Jen Hsu¹; Kathryn A. Carson¹; Bernard G. Jaar¹; Jill A. Marsteller¹; Lawrence J. Appel¹; L. Ebony Boulware². ¹Johns Hopkins Medical Institutions, Baltimore, MD; ²Duke University School of Medicine, Durham, NC. (Tracking ID #1938904)

BACKGROUND: African Americans are disproportionately affected by advanced CKD and risk factors for CKD progression. Primary care providers (PCP) care for most patients with CKD and are well-positioned to treat CKD risk factors. However little is known about racial differences in the provision of primary care related to CKD management.

METHODS: We conducted a cross-sectional study of 1800 patients (765 African American, 1035 White) with an estimated glomerular filtration rate between 15 and 59 ml/min/1.73 m² to quantify racial differences in CKD management. Using electronic medical record data from 6 Baltimore area primary care clinics ($n=49$ PCPs), we obtained information on patient race/ethnicity and receipt/achievement of CKD care goals recommended by clinical practice guidelines during a 12 m period (4/12–3/13). We also obtained information on patient age; sex; CKD severity; presence and control of diabetes, hypertension, or CVD; and number of PCP visits during the 12-month study period. We performed random-effects multivariable logistic regression to account for clustering of patients within physicians.

RESULTS: Compared to Whites, African Americans were younger, had greater CKD severity, greater prevalence of hypertension and diabetes, and more frequent utilization of primary care (Table 1). Among patients with diabetes, African Americans were more likely to receive a hemoglobin A1c test compared to Whites (96 % vs. 90 %, respectively, $p=0.004$). There were no statistically significant differences in patients' receipt of other recommended care, including serum creatinine, urine protein, lipid profile, or hemoglobin assessments. African Americans were less likely than whites to achieve a BP goal of <140/90 (63 % vs. 72 %, $p=0.002$) and an LDL goal of <100 (54 % vs 64 %, $p<0.001$). There was no racial disparity in achieving a hemoglobin A1c goal of <7 among patients with diabetes.

CONCLUSIONS: Compared to Whites, African Americans with CKD were less likely to achieve recommended management goals for blood pressure and cholesterol. Further studies are needed to understand the reasons for these disparities in achievement of CKD management goals and their impact on subsequent clinical outcomes.

Table 1: Patient Characteristics

Patient Characteristics	African American (n=765)	White (n=1035)	P value
	n (%)	n (%)	
Age			<0.001
18–44 years	15 (2.0)	8 (0.8)	
45–59 years	99 (12.9)	79 (7.6)	
60–74 years	296 (38.7)	379 (36.6)	
75+ years	355 (46.4)	569 (55.0)	
Female	491 (64.2)	599 (57.9)	0.007
Hypertension	671 (87.7)	828 (80.0)	<0.001
Diabetes	403 (52.7)	359 (34.7)	<0.001
Cardiovascular Disease	432 (56.5)	642 (62.0)	0.017
Baseline CKD Stage			0.019
Stage 3a	434 (56.7)	605 (58.5)	
Stage 3b	237 (31.0)	344 (33.2)	
Stage 4	94 (12.3)	86 (8.3)	
Number of PCP visits in study period			0.003
1–2 visits	191 (25.0)	339 (32.8)	
3–6 visits	409 (53.5)	503 (48.6)	
9–11 visits	93 (12.2)	120 (11.6)	
>11 visits	72 (9.4)	73 (7.1)	

Table 2: Achievement of CKD Care Goals among African American and White Patients

	Achievement of Recommended CKD Care Goals (%)			P value*
	Total	African American	White	
Assessment Goals				
Creatinine	88.1	88.5	87.8	0.89
Urine protein quantification	25.1	30.7	20.9	0.69
Lipids	70.5	71.9	69.5	0.38
Hemoglobin	67.8	67.1	68.3	0.24
Hemoglobin A1c**	93.4	96.0	90.5	0.004
Management Goals				
BP < 140/90	68.5	63.2	72.4	0.002
LDL < 100	59.7	54.0	64.1	<0.001
Hemoglobin A1c < 7**	57.2	56.1	58.5	0.19

*Adjusted for age, sex, hypertension, diabetes, cardiovascular disease, baseline eGFR, PCPs volume of CKD patients, and number of PCP visits during study period,

**Assessed only among patients with diabetes

RACIAL/ETHNIC DIFFERENCES IN PALLIATIVE CARE CONSULTATION FOR INPATIENTS WITH ADVANCED CANCER

Rashmi K. Sharma¹; Kenzie A. Cameron¹; Jamie Von Roenn¹; Joan S. Chmiel¹; Holly G. Prigerson²; Frank Penedo¹.
¹Northwestern University, Chicago, IL; ²Cornell Medical College, New York City, NY. (Tracking ID #1926304)

BACKGROUND: Racial/ethnic minorities with advanced cancer are less likely to receive palliative care and hospice services than non-Hispanic whites (NHW) and more likely to receive intensive, non-curative treatment at the end of life, yet little is known about racial/ethnic differences in rates of inpatient palliative care consultation (PCC). We sought to evaluate the association between race/ethnicity and PCC for advanced cancer patients.

METHODS: We used the electronic medical record (EMR) to identify all patients with metastatic cancer hospitalized between January 1, 2009 and December 31, 2010 at an urban academic medical center. Patient-level multivariable logistic regression was used to evaluate the association between race/ethnicity and PCC.

RESULTS: 6288 advanced cancer patients (69 % NHW, 19 % African American (AA), 6 % Hispanic) were hospitalized during the study period of which 1086 patients had a PCC. More AA (22 %) and Hispanic patients (20 %) received an inpatient PCC compared to NHW patients (16 %) ($p<0.001$). In univariate analyses, AA race/ethnicity (OR 1.49, 95 % CI 1.27–1.74), Hispanic ethnicity (OR 1.33, 95 % CI 1.01–1.74), and insurance [Medicaid (OR 1.87, 95 % CI 1.48–2.36) and Medicare (OR 1.24, 95 % CI 1.07–1.42), each vs. private insurance] were associated with higher odds of PCC. Greater severity of illness (measured using the APR-DRG severity of illness score) was linearly associated with higher odds of PCC (trend test $p<0.001$). After adjusting for insurance status, race/ethnicity, prior hospitalization, and severity of illness, AA and Medicaid patients had higher odds (OR 1.28, 95 % CI 1.08–1.52, and OR 1.60, 95 % CI 1.23–2.09) of inpatient PCC than NHW and private insurance patients, respectively.

CONCLUSIONS: Hospitalized AA patients with advanced cancer were more likely to receive a PCC than NHW patients, even after adjusting for insurance status and severity of illness, although rates of PCC remained low. Our findings of increased receipt of PCC among AA patients in the hospital appear contrary to studies reporting decreased access to palliative care services by racial/ethnic minorities in the outpatient setting. Better understanding of the factors that are driving higher rates of inpatient PCC rates for AA patients with advanced cancer may thus help to inform the development of interventions to improve access to palliative care for AA patients across other settings.

Factors associated with inpatient palliative care consultation for patients with advanced cancer

Variables	Bivariate Analysis		Multivariate Analysis*	
	OR	95 % CI	OR	95 % CI

RANDOMIZED CONTROLLED TRIAL OF A CULTURALLY ADAPTED, AUTOMATED TELEPHONE EXERCISE COACH TO IMPROVE PHYSICAL ACTIVITY AMONG HYPERTENSIVE AFRICAN-AMERICANS

Julien J. Dedier¹; Julie A. Wright³; Robert H. Friedman¹; Timothy Heeren². ¹Boston University, Boston, MA; ²Boston University, Boston, MA; ³University of Massachusetts, Boston, MA. (Tracking ID #1939226)

BACKGROUND: Regular physical activity (PA) of moderate or greater intensity (MOD+PA) can reduce blood pressure (BP). However, hypertensive urban minority patients may face logistical obstacles to participation in brick-and-mortar PA programs. Automated PA programs delivered by telephone can mitigate these obstacles. We conducted an RCT to test the ability of an automated, interactive, culturally adapted telephone exercise coach to (1) increase PA and (2) lower BP in urban African-Americans (AA) with poorly controlled hypertension (HTN).

METHODS: Subjects were sedentary, hypertensive, AA adult primary care patients at an urban safety net hospital or 2 affiliated health centers. Potential subjects were identified in the electronic medical record database and sent an invitation letter from the practice. Study staff called patients to confirm eligibility and enroll them. The intervention was Telephone-Linked Care for PA (TLC-PA)—a computerized system that ‘converses’ with patients by telephone using pre-recorded human speech. It helps patients set PA goals, devise a plan to meet them, monitor their progress toward these goals, and helps patients overcome barriers that arise. Guided by Social Cognitive Theory and the Transtheoretical Model of behavioral change, TLC-PA conversations were tailored to the user’s level of behavior and motivation. Content was also culturally adapted to aspects of PA relevant to urban AA in Boston. Patients randomized to TLC-PA were scheduled to receive 12 weekly TLC-PA calls of roughly 10 min each. Control participants received usual primary care and an educational brochure on HTN. The primary study outcomes were (1) change in minutes of MOD+PA from baseline to 3 months; and (2) change in SBP from baseline to 3 months. PA was measured using 2 validated surveys: (1) the 7-question PA set from the 2009 Behavioral Risk Factor Surveillance System (BRFSS) survey; and (2) the 7-Day Physical Activity Recall (PAR).

RESULTS: 253 patients completed the baseline assessment (123 TLC-PA, 130 control). Mean age was 58 years. Seventy-three percent were female and 20 % partnered. Eighty-three percent reported highschool/GED-level education. Twenty-eight percent were employed full- or part-time, and the median annual household income was \$10 K–\$20 K. Baseline BP in the TLC-PA and control groups were 136.4/83.5 mmHg and 138.9/81.5 mmHg, respectively. Among patients who

completed the final 3-month assessment, self-reported minutes of MOD+PA/week increased significantly more in the TLC-PA group than controls from baseline to 3 months on both the BRFSS survey (143.2 min. TLC-PA vs. 110.2 min. controls, $p=.007$) and the 7-day PAR (55.1 min. TLC-PA vs. 28.1 min. controls, $p=.022$). The odds of meeting the national recommendation of ≥ 150 min/week of MOD+PA at 3 months was statistically greater in the TLC-PA group than in controls on the BRFSS (OR 2.9, $p=.001$), but not on the PAR (OR 1.7, $p=.098$). Despite these increases in MOD+PA, change in SBP from baseline to 3 months did not differ significantly between experimental groups.

CONCLUSIONS: TLC-PA was associated with a significant increase in self-reported MOD+PA compared to usual primary care alone. Patients also rated TLC-PA highly on content, convenience and user-friendliness. Given their convenience, scalability, and ability to deliver tailored messages, automated telecommunications systems can promote PA self-management in urban African-Americans with HTN.

RANDOMIZED TRIAL OF TELEPHONE NURSE CASE CO-MANAGEMENT OF DIABETES AND HYPERTENSION IN COMMUNITY PRACTICE
David Edelman^{1,2}; Cynthia J. Coffman^{3,2}; Rowena Dolor¹; Jennifer H. Lindquist^{2,1}; Katherine C. Pereira⁴; Bradi B. Granger^{5,4}; Alice M. Neary¹; Amy C. Harris^{2,1}; Hayden Bosworth^{1,2}.¹Duke University Medical Center, Durham, NC; ²Durham VA Medical Center, Durham, NC; ³Duke University Medical Center, Durham, NC; ⁴Duke University Medical Center, Durham, NC; ⁵Duke University Medical Center, Durham, NC. (Tracking ID #1935667)

BACKGROUND: Several trials have demonstrated the efficacy (best-case potency) of nurse telephone case management for diabetes (DM) and hypertension (HTN). However, these trials were performed in academic or vertically-integrated systems. The extent to which these clinical improvements translate to "real world" practices is unknown. Our objective was to assess the effectiveness (real-world potency) of nurse-run behavioral co-management of blood sugar and blood pressure among patients with both diabetes and HTN.

METHODS: The study was a patient-level randomized, controlled trial among 9 practices in a practice-based research network of community primary care practices. Patients were age ≥ 21 , had both type 2 DM and HTN, had to have inadequately controlled DM (Hemoglobin A1c (A1c) $\geq 7.5\%$) but could have well controlled HTN. All patients were called by a nurse with experience in DM and HTN management every two months for two years, for a total of 12 calls. Intervention arm patients received DM- and HTN- focused behavioral content; the content was targeted to individuals' needs (eg, only sedentary subjects received physical activity advice, only smokers received smoking cessation advice). Content was informed by motivational interviewing and attempted to identify and resolve specific barriers to healthful behaviors (eg, healthful eating, physical activity, medication adherence). Medications were not managed. Control patients received non-tailored, non-interactive information regarding health issues unrelated to DM and HTN (eg, skin cancer prevention) at the same frequency as intervention calls. Systolic blood pressure (SBP) and A1c were co-primary outcomes; diastolic blood pressure (DBP), weight and self-efficacy (by Perceived Competence scale, PCS, scale 0-4) were also measured. Subjects were assessed at baseline, 6, 12, and 24 months; 12 months was the primary outcome. Analyses were performed by linear mixed modeling, adjusting for statistical clustering by practice.

RESULTS: 377 subjects were enrolled; 193 randomized to the intervention, 184 to control. The number of subjects per practice ranged from 16 to 104. Subjects were 55 % female, 50 % white; their mean age was 59 (SD=11) years and mean BMI was 36.3 (SD=7.7) kg/m². Mean baseline A1c was 9.0 % (SD=1 %) and mean SBP was 142 mmHg (SD=20). Intervention patients received 78 % of nurse calls; control patients, 81 %. Eighty-two percent of all data points were obtained; 80 % of intervention patients and 76 % of control patients reached the 12 month time point. Expressing differences as (intervention - control), at 12 months, intervention patients had similar A1c [diff=-0.2 %, 95%CI (-0.6, 0.1), $p=0.23$] and SBP [diff=-1.3 mmHg, 95%CI (-5.6, 3.0), $p=0.54$] to control patients. DBP (diff=1.0 mmHg, $p=0.36$) and weight (diff=1.1 kg, $p=0.21$) were likewise similar between control and intervention patients. Self-efficacy was slightly worse among intervention patients (diff=-0.25, $p=0.006$). Results were similar at the 6 and 24 month time points.

Analyses of patients who completed at least 10 encounters were not different from the primary analyses.

CONCLUSIONS: In 9 community, fee-for-service practices, telephonic nurse case management did not lead to improvement in A1c or SBP. The lack of impact on completers suggests that this lack of potency is not due to dropout. Gains seen in telephonic, behavioral self-management interventions in optimal settings may not translate to all primary care settings.

READINESS FOR INTERPROFESSIONAL LEARNING AMONG MEDICAL, NURSING, AND PHYSICIAN ASSOCIATE STUDENTS AT AN AMERICAN UNIVERSITY Jaideep S. Talwalkar^{1,2}; Deborah B. Fahs³; Gerald Kayingo¹; Linda H. Pellico³. ¹Yale School of Medicine, New Haven, CT; ²Yale School of Medicine, New Haven, CT; ³Yale School of Nursing, New Haven, CT. (Tracking ID #1937558)

BACKGROUND: The Liaison Committee on Medical Education recently adopted a new standard for interprofessional curricular experiences citing the importance of collaborative education and practice for improved patient outcomes, safety, and quality of care. Currently at our university there are few opportunities for medical, nursing, and physician associate students to collaborate. A curricular redesign is in progress that will provide robust interprofessional learning opportunities for students from the start of training longitudinally through graduation. The aim of this study was to determine baseline perceptions among first year health professions students at one American university towards collaborative learning and practice.

METHODS: First year students in three professional programs [medical ($n=101$), nursing ($n=81$), and physician associate ($n=35$)] were sent an anonymous online survey in January 2012 which included six items related to demographic information, as well as the 19-item Readiness for Interprofessional Learning Scale (RIPLS). This validated, widely-utilized scale measures the readiness of healthcare students for shared learning. Scores on the RIPLS and its four subscales were compared among the three groups of students using SAS 9.3 by the general linear model.

RESULTS: Surveys were completed by 70 (69 %) medical, 71 (88 %) nursing, and 25 (71 %) physician associate students. Scores on the RIPLS indicated that all three groups of students scored in the high range, indicating readiness for shared learning. Female students, those with advanced degrees, and those with healthcare experience prior to enrollment in health professional school had significantly higher scores than their counterparts. After controlling for differences in demographic factors, nursing students scored significantly higher (83.06) than physician associate (76.84, $p<0.0001$) and medical (76.41, $p<0.0001$) students. There was no difference between physician associate and medical student total scores.

CONCLUSIONS: Health professions students from three training programs within an American university demonstrated readiness for interprofessional learning early in their academic programs, however nursing students demonstrated greater readiness than medical and physician associate students. Our findings are similar to those reported in studies from Canada and New Zealand, but different than reports from the United Kingdom and Singapore. Previous work suggests that entering nursing students think collaboratively, in contrast to medical students who think in individualistic terms. It is possible that students with an interest in or a skill set suited for team-based care are attracted to the nursing profession. In contrast, physician associate students learn in the medical model, and the scores of these two groups of learners were similar. In order to optimize the value of curricular innovations that emphasize interprofessional education, it may be necessary to create learning groups that balance predictive features of readiness for interprofessional learning, such as program type, gender, and prior healthcare experience or graduate degree. Extrapolation of predictive features across countries may not be appropriate.

READMISSION REDUCTION INITIATIVE (RRI): CHARACTERIZING THE 30-DAY READMISSION POPULATION AND IDENTIFYING PREDICTORS OF PREVENTABILITY Shone Almeida; Edward Ha; Ashley Busuttil; Nasim Afsarmanesh. Ronald Reagan Medical Center at UCLA, Los Angeles, CA. (Tracking ID #1916190)

BACKGROUND: Prior studies have estimated that one in five patients is rehospitalized within a 30-day period. We sought to characterize the 30-day readmission population at a major academic medical center, the Ronald Reagan Medical Center at the University of California, Los Angeles (RRUCLA). This study also assesses the root cause and preventability of each readmission with the aim of finding potential predictors of preventable readmissions.

METHODS: From 1/1/2012 to 1/16/2013, 3,848 cases of 30-day readmissions were identified. Chart abstractions were performed by physicians, medical students, and nurses. Documentation review was limited to the history and physical (H&P) and discharge summary for the index admission and readmission event.

RESULTS: To date, 611 chart abstractions have been completed, of which 67.4 % were found to be not preventable (NP), 23.5 % potentially preventable (PP), and 9.1 % preventable (P). The majority of readmissions were due to relapse, or worsening of chronic illness, accounting for approximately 44.5 % of cases; another 30.4 % were due to a new, unrelated event. Planned admissions, medication or procedure adverse events, and inadequate discharge planning accounted for 11.3 %, 6.5 %, and 4.1 % respectively. Quality of care during the index admission and access to care issues together accounted for just over 3.1 % of abstracted cases.

CONCLUSIONS: The data shows that the number of unpreventable admissions far outnumbers preventable ones. Trends point to high utilization of the ER, new anticoagulation starts, discharge medication reconciliation, and effective post-discharge follow-up as potential targets of future intervention. However, the current sample size is too small to draw any definite conclusions regarding predictors of preventability.

RECEIPT OF ALCOHOL-RELATED ADVICE AND QUALITY OF CARE AMONG VETERAN OUTPATIENTS WITH UNHEALTHY ALCOHOL USE
Joseph Simonetti^{1,3}; Gwen T. Lapham^{4,2}; Emily Williams^{2,3}. ¹University of Washington, Seattle, WA; ²Seattle-Denver HSR&D COIN, VA Puget Sound, Seattle, WA; ³University of Washington, Seattle, WA; ⁴Group Health Research Institute, Seattle, WA. (*Tracking ID #1938960*)

BACKGROUND: Brief intervention, including advice to reduce or abstain from drinking, is widely recommended for primary care patients with unhealthy alcohol use, but rarely implemented. One cited barrier to implementation is providers' assumptions that patients do not want to discuss their drinking or may react negatively to such interventions. However, among primary care patients with unhealthy alcohol use who participated in an intervention trial to address their drinking, those who reported receipt of alcohol-related advice rated their care as higher quality than those not reporting advice. It is unknown whether a similar association exists among a more general sample of outpatients. Our aim was to determine whether receipt of alcohol-related advice was associated with perceptions of quality of care among a general sample of Veteran outpatients who screened positive for unhealthy alcohol use and responded to a mailed survey.

METHODS: This retrospective, cross-sectional study included Veteran outpatient respondents to the VA Survey of Healthcare Experiences of Patients (Fiscal Year 2010, response rate 53 %) who screened positive for unhealthy alcohol use on the 3-item Alcohol Use Disorders Identification Test (AUDIT-C) included in the survey (score >3 for women, >4 for men), responded to a question regarding receipt of alcohol-related advice from a VA provider in the past year (yes/no), and to two questions assessing patient ratings of their VA provider and overall VA health care. We used logistic regression to assess the association between receipt of alcohol-related advice and two patient-reported outcomes: patient ratings of their VA provider and their overall VA health care (range 0–10, dichotomized ≥9 to indicate high quality). Models were adjusted for age, gender, race, education, and self-reported health status and were clustered to account for correlation of outcomes at the facility level.

RESULTS: Among 21,912 Veterans who completed the 2010 survey, 3,760 screened positive for unhealthy alcohol use and had complete data. Overall, the mean age of the study sample was 64.4 years; 96.3 % were male, 79.7 % were non-Hispanic White, 91.8 % completed high school and 28.3 % reported their health status as very good or excellent. Nearly half (44.3 %) of the study sample reported receiving alcohol-related advice in the past year, and 68.8 % and 56.2 % of respondents rated their providers and VA health care as high quality, respectively. In adjusted models, patients who reported receipt of alcohol-related advice were more likely than those who did not to rate their provider (OR 1.38; 95 % CI 1.16–1.64) and VA health care (OR 1.29; 95 % CI 1.11–1.51) as high quality.

CONCLUSIONS: Results from this cross-sectional analysis among Veterans with unhealthy alcohol use demonstrate that receipt of alcohol-related advice—a key

component of efficacious brief intervention—is associated with patient-reported indicators of high quality care. These findings are consistent with those of a previous study in a more limited population, and are in opposition to provider concerns that delivering such advice may adversely affect patients' perceptions of their care.

RECENT TRENDS AND REGIONAL VARIATION IN OPIOID ANALGESIC EXPOSURE IN THE VETERANS HEALTH ADMINISTRATION William Becker^{1,2}; Jian Gao³; E. Jennifer Edelman²; Eileen Moran³; David A. Fiellin²; Robert D. Kerns^{1,2}. ¹VA Connecticut Healthcare System, West Haven, CT; ²Yale University, New Haven, CT; ³Veterans Health Administration, Washington, DC. (*Tracking ID #1939112*)

BACKGROUND: Given data demonstrating modest efficacy and potential for serious harms—including addiction, diversion, overdose and death—opioid analgesic prescribing for non-cancer pain has become increasingly controversial. Within the Veterans Health Administration (VHA), multiple efforts including clinical practice guideline updates, policy changes and educational efforts, have promoted safe opioid prescribing. Risk of harm has been linked to both dose and duration of opioid therapy, which, when considered together, can be defined as opioid exposure. We sought to characterize recent trends and regional variation in opioid analgesic exposure in the VHA, the largest integrated health system in the U.S.

METHODS: Using the VHA Decision Support System's Pharmacy National Data Extracts we identified all outpatient, oral or transdermal opioid prescriptions for veterans without a cancer diagnosis from 2005 to 2013. Opioids for the treatment of addiction were excluded. We calculated opioid exposure by first converting each prescription to a standard morphine equivalent dose, then multiplying by pill quantity extrapolated over the number of days supplied. Multiple co-occurring prescriptions for the same patient were added together. To calculate per capita data, we aggregated opioid exposure for the entire health system by year and divided it by the total number of patients in the system (exposure per capita) and then by prescription recipient (exposure per recipient). For 2013 only, we then calculated exposure per capita and exposure per recipient for each of VHA's 140 facilities to assess regional variation; the catchment areas for these facilities are non-overlapping and encompass the entire U.S.

RESULTS: Over 9 years, approximately 54.1 million prescriptions written for nearly 2.7 million veterans met the inclusion criteria. Exposure per capita increased 18 % nationally from 986 mg in 2005 to 1,159 mg in 2013, while exposure per recipient increased 14 % from 5,337 mg in 2005 to 6,088 mg in 2013. Both exposure metrics peaked in 2012 and were slightly lower in 2013. The analysis by facility revealed a nearly 3.2-fold variation in exposure per capita from the mean of the lowest quintile (605 mg) to the mean of the highest quintile (1,931 mg); and a 2.2-fold variation in exposure per recipient from the mean of the lowest quintile (3,927 mg) to mean of the highest quintile (8,629 mg).

CONCLUSIONS: Recent trends in per capita and per recipient opioid exposure indicate stabilization in the use of opioids for non-cancer pain in VHA which may reflect successful dissemination and uptake of practice guidelines, policies and education. Further research is needed to explain and ameliorate marked regional variation in the use of opioids in non-cancer pain.

RECTAL CANCER: CHARACTERISTICS AND SURVIVAL RATES OF YOUNG VS. OLD Shams Mistry; Charles Andrew T. Chacko; Harish Madala; Logrono AlMarieGrace; Jill Germand; Radhika Kakarala. McLaren Regional Medical Center, Flint, MI. (*Tracking ID #1921544*)

BACKGROUND: Rectal cancer is detected at a later stage in younger patients (YP) (< 50) due to lack of screening in this age group. There has been an increased incidence of rectal cancer in YP, but they are underrepresented in research studies. The aim of our study is to compare characteristics of rectal cancer and survival outcome in YPs (18–49 years) vs older patients (50+) using the Surveillance, Epidemiology, and End Results (SEER) database.

METHODS: We analyzed a retrospective cohort of patients diagnosed with rectal cancer in the SEER national cancer registry from 1991 to 2010. This National Cancer Institute database is a cancer registry covering approximately 26 % of the US population across several geographic regions. It is the largest publicly available domestic cancer database. Using the SEER database, we reviewed patients >18 years of age with rectal adenocarcinoma from 1991 to 2010. Continuous and categorical variables are reported using mean (SD), proportions, and percentages. Univariate analysis was done using T-test and Chi-square tests respectively. Multivariate Cox

regression analysis was used to evaluate risk adjusted outcomes and to predict the hazard of dying. Kaplan Meier method was used to estimate the survival function.

RESULTS: We included 102,167 patients in our study. YPs with rectal carcinoma were more likely to be African American (11.9 % vs 8.8 %; $p<0.001$), Hispanic (13.3 % vs 8.3 %; $p<0.001$) and Asian (10.9 % vs 8.3 %; $p<0.001$) as compared to the older age group. YPs were more likely to present with distant metastasis (16.7 % vs 13.4 %; $p<0.001$) and had more poorly differentiated tumors (13.3 % vs 12.1 %; $p<0.001$). YPs also received more cancer directed surgery (84 % vs 80 %; $p<0.001$) and post-operative radiation (52 % vs 39.8%; $p<0.001$) compared to their older counterpart. In contrast to previous studies the 5 year survival was better for younger patients (74.3 % vs 70.7 %; $p<0.001$ {Table 1}). After controlling for gender, race, marital status, grade, stage, cancer specific surgery and post-operative radiation, multivariate Cox regression analysis revealed that age is an independent predictor of death, and younger patients with rectal cancer had a lower risk of dying (HR 0.693; $p<0.001$).

CONCLUSIONS: In previous studies younger patients with rectal cancer were found to have poorer or equivalent survival compared to older patients. In contrast, our study shows that young patients less than 50 years of age, have advanced stage rectal cancer at diagnosis but have better survival.

Table 1: Five-year relative survival for rectal cancer patients

Stage of rectal cancer	Young (< 50 year) N=12,268	Older (≥ 50 years) N=83,232	P- VALUE
Localized	280 (93.3 %)	3,837 (87.7 %)	<0.001
Regional	792 (74.2 %)	6,201 (66.6 %)	<0.001
Distant	1,324 (17.3 %)	7,110 (13.4 %)	<0.001
OVERALL	2,516 (74.3 %)	18,802 (70.7 %)	<0.001

RECURRENT VENOUS THROMBOEMBOLISM IS ASSOCIATED WITH AN IMPAIRED LONG-TERM QUALITY OF LIFE IN THE ELDERLY Marie Méan¹; Andreas Limacher²; Drahomir Aujesky¹. ¹Bern University Hospital, Bern, Switzerland; ²University of Bern, Bern, Switzerland. (Tracking ID #1928105)

BACKGROUND: In patients with acute venous thromboembolism (VTE), long-term health-related quality of life (QOL) is substantially influenced by the development of chronic complications, such as the post-thrombotic syndrome. However, whether acute complications, such as recurrent VTE or major bleeding, impair long-term QOL after an index VTE is uncertain.

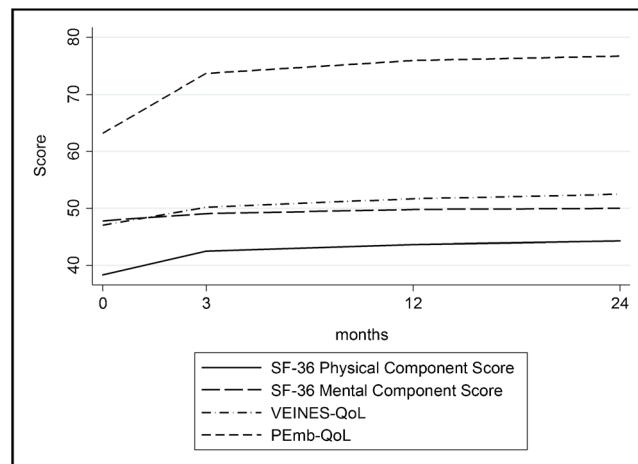

METHODS: In a prospective multicenter Swiss cohort study, we enrolled consecutive patients aged ≥ 65 years with an acute VTE between 09/2009 and 08/2011. Generic QOL was assessed at baseline and at 3, 12, and 24 months using the Physical Component Score and the Mental Component Score of the SF-36 questionnaire. Disease-specific QOL was assessed using the VEINES-QoL/Sym questionnaire in patients with deep vein thrombosis and the PEmb-QoL questionnaire in patients with pulmonary embolism. We examined the effect of VTE recurrence and major bleeding on change in QOL over a 24-month follow-up period using repeated measures linear regression analyses based on multiply imputed data, adjusting for age, gender, baseline QOL, time of QOL assessment, education, living status, smoking status, physical activity, risk of falls, body mass index, overt pulmonary embolism, provoked VTE, recent immobilization, recent major surgery, prior varicose vein surgery, cancer, cardiovascular comorbidities, hemi/paraplegia, chronic lung disease, chronic renal disease, diabetes mellitus, polypharmacy (>4 drugs), and the occurrence of the postthrombotic syndrome during follow-up.

RESULTS: Of 745 patients with acute VTE (median age 75 years), 68 (9 %) experienced recurrent VTE and 82 (11 %) a major bleeding within 24 months. Twelve patients (2 %) had an intracranial bleeding. On average, generic and disease-specific QOL scores improved during follow-up (Figure). Patients who developed a VTE recurrence or a major bleeding had lower QOL scores and less improvement in QOL. Adjusted repeated measures analyses showed that patients with recurrent VTE had significantly less increase in disease-specific QOL during follow-up (Table), whereas patients with major bleeding experienced less increase in generic mental QOL.

CONCLUSIONS: Elderly patients with acute VTE who experience recurrent VTE have significantly less improvement in disease-specific QOL, whereas patients who develop major bleeding have significantly less improvement in mental QOL. Acute complications, such as recurrent VTE or major bleeding, impair long-term QOL after an index VTE.

Type of complication and quality of life within 24 months

Type of complication	QOL measure	Adjusted difference in the average change of score points	P-value
		(95 % confidence interval)	
VTE recurrence	SF-36 Physical Score Component	-1.67 (-3.43 to 0.1)	0.06
	SF-36 Mental Score Component	1.31 (-1.05 to 3.68)	
	VEINES-QoL/Sym	-2.82 (-5.26 to 0.38)	
	PEmb-QoL	-5.04 (-9.43 to -0.65)	
	SF-36 Physical Score Component	-1.36 (-3.56 to 0.84)	
	SF-36 Mental Score Component	-3.45 (-6.20 to 0.70)	
Major bleeding	VEINES-QoL/Sym	-1.80 (-5.54 to 1.95)	0.33
	PEmb-QoL	0.22 (-4.29 to 4.73)	

REFINED APPROPRIATENESS CRITERIA FOR URINARY CATHETERS IN HOSPITALIZED PATIENTS Jennifer Meddings¹; Sanjay Saint^{1,2}; Karen E. Fowler²; Elissa Gaius²; Sarah L. Krein^{1,2}; Steven J. Bernstein^{1,2}. ¹University of Michigan, Ann Arbor, MI; ²VA Ann Arbor Healthcare System, Ann Arbor, MI. (Tracking ID #1933401)

BACKGROUND: Interventions to reduce inappropriate urinary catheter use are implemented using lists of appropriate and inappropriate criteria (e.g., CDC's 2009 catheter-associated urinary tract infection guideline), informed by limited evidence without substantial multidisciplinary input. Implementation is challenging due to broad interpretations of indications (e.g., "critical illness") and common catheter uses not addressed in lists (e.g., patient request). The objective of our project was to refine criteria for "appropriate" use (i.e., benefits outweigh risks) of Foley catheters, intermittent straight catheters (ISC), and external "condom" catheters in hospitalized adults on medical services.

METHODS: Using the RAND/UCLA Appropriateness Method, the literature was systematically reviewed to summarize risks, benefits, and potential catheter indications. A 15 member multi-disciplinary panel of physicians, nurses, and infection preventionists assessed 299 catheter indications (e.g., urinary retention, urine collection to diagnose/monitor, etc.) on a scale of 1 (highly inappropriate) to 9 (highly appropriate). Scenarios accounted for incontinence, illness severity, difficulty turning, and catheter placement issues. Catheter use was assessed by median scores, as inappropriate (1–3), appropriate (7–9) or uncertain (4–6 or

having 5 appropriate and inappropriate ratings, regardless of median [termed “disagreement”].

RESULTS: Overall, 253 (85 %) ratings were scored as appropriate (88) or inappropriate (165); 46 (15 %) were uncertain. Catheter appropriateness of each catheter type was summarized in algorithms for clinical use as illustrated in the Figure.

CONCLUSIONS: Refined appropriateness criteria will inform small and large-scale efforts focusing on avoiding placement and prompting removal of unnecessary catheters. The algorithms further refine indications and non-indications for Foleys, in addition to appropriateness for ISCs and condom catheters as alternatives in each clinical scenario.

Figure: Sample Algorithm

Appropriateness of urinary catheter to collect a single urine sample

Can urine be collected by commode, urinal or bedpan?

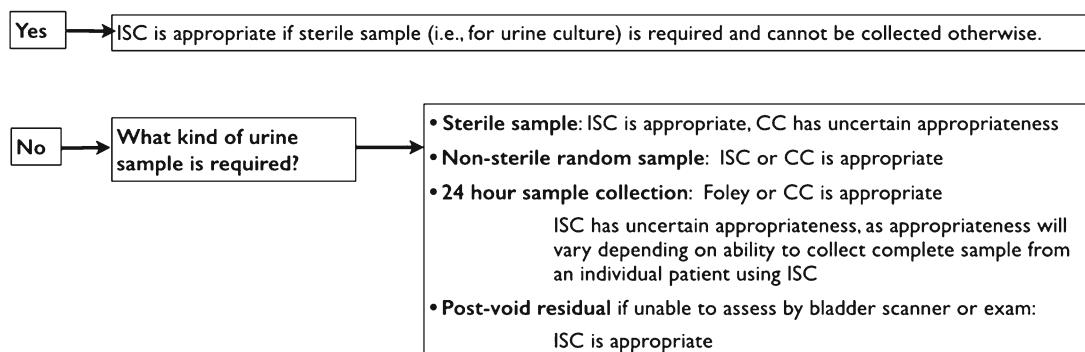

Figure Notes:

Foley=indwelling transurethral catheter; ISC=intermittent straight catheterization; CC=external “condom” catheter in male patient.

Appropriateness of other catheter types (such as suprapubic catheters, or nephrostomies) is not addressed in this algorithm.

Catheter types are listed as “uncertain appropriateness” if expert panel was undecided with median rating 4-6 or had disagreement with ≥5 ratings as inappropriate and ≥5 ratings as appropriate.

Note: This project yielded a total of 12 clinical algorithms, each providing guidance on appropriateness of use of Foley, CC, or ISC for a clinical scenario when urinary catheters are commonly considered for placement. This Figure provides one of the algorithms as a sample of the algorithms generated by this project.

REGIONAL CORRELATION IN BRAND-NAME PRESCRIPTION DRUG USE AMONG VA AND MEDICARE PART D PATIENTS WITH DIABETES

Timothy Anderson¹, Julie M. Donohue², Nancy E. Morden³, Xinhua Zhao⁴, Maria Mor⁴; Carolyn Thorpe^{4,5}; Chester Good^{4,6}; Michael J. Fine^{4,6}; Walid F. Gellad^{4,6}.

¹UPMC, Pittsburgh, PA; ²University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; ³Geisel School of Medicine at Dartmouth, Dartmouth, NH; ⁴VA Pittsburgh Healthcare System, Pittsburgh, PA; ⁵University of Pittsburgh School of Pharmacy, Pittsburgh, PA; ⁶University of Pittsburgh School of Medicine, Pittsburgh, PA. (Tracking ID #1938573)

BACKGROUND: Older adults with diabetes covered by Medicare Part D are substantially more likely to receive brand-name drugs than those who receive care within the VA Healthcare System. There is substantial geographic variation in brand-name use in both systems. However, no prior studies have examined whether regions with high brand-name use in Medicare are also high in the VA. Our aim was to identify whether such regional correlation exists, which might suggest that local practice patterns affect prescribing independent of insurance benefit structures.

METHODS: Using a retrospective cohort study design, we assessed prescription use across 306 U.S. hospital referral regions (HRRs) for 1,061,095 Medicare Part D beneficiaries and 510,485 Veterans receiving care in the VA who were ≥65 and had a diagnosis of diabetes in 2008. We examined the percentage of patients who filled brand

name drugs for oral hypoglycemics, statins, and angiotensin-converting enzyme (ACE) inhibitors or angiotensin-receptor blockers (ARBs) and the percentage of patients taking long-acting insulin who filled analogue prescriptions, in order to examine medications with and without restricted access on the VA formulary (the brand name oral medications and analogue insulins, respectively). We calculated correlations between Medicare and VA brand name use within HRRs for each drug class. Second, we examined potential sources of regional correlation between VA and Medicare, including state laws requiring mandatory generic substitution and requiring patient consent for substitution, physician and specialist availability and presence of a medical school or VA Medical Center within the HRR, by comparing these variables between regions in the highest quintile of brand use in both Medicare and VA and regions in the lowest quintile in both systems. We adjusted all brand-name use for individual-level socioeconomic and health-status differences across HRRs using logistic regression models.

RESULTS: The correlation in brand-name use between Medicare Part D and VA at the HRR-level varied by drug class, with the strongest correlation in use of long-acting insulin analogues ($r=0.31, p<0.001$), modest correlation of 0.20 ($p<0.001$) for oral hypoglycemics and 0.18 ($p<0.001$) for statins, and no significant association for ACE/ARBs ($r=0.03, p=0.63$). Within the subset of 77 HRRs containing both a medical school and VA Medical Center, the correlation between systems was higher for statins ($r=0.27, p<0.001$) but similar in the other three drug classes. Of HRRs in the highest quintile of brand statin use in Medicare, 38 % were also in the highest

quintile in VA ('high-high' regions). 'High-high' regions for brand statin use had on average more cardiologists (8.2 vs 4.9), more endocrinologists (1.8 vs 0.9) and fewer family physicians (21.2 vs. 33.4) per 100,000 residents than 'low-low' regions.' Generic substitution laws did not differ between high-high and low-low regions.

CONCLUSIONS: We found modest regional correlations in brand name use of oral hypoglycemics, statins and insulin analogues but not ACE/ARBs between the VA and Medicare. Patterns of prescribing were more similar between VA and Medicare for medications with fewer VA formulary access restrictions. These results suggest that a regional 'culture' impacts prescribing, beyond the health status of individuals and the health system in which they are treated.

RELATIONSHIP BETWEEN DEPRESSIVE SYMPTOMS, ANTIDEPRESSANT USE, AND PATIENT ATTITUDES AND BEHAVIORS AMONG LOW-INCOME PATIENTS WITH TYPE 2 DIABETES Caroline Presley; Ken Wallston; David Schlundt; Chandra Y. Osborn; Sunil Kripalani; Shari D. Barto; Russell L. Rothman. Vanderbilt University Medical Center, Nashville, TN. (*Tracking ID #1934768*)

BACKGROUND: This study aimed to evaluate the impact of depressive symptoms and antidepressant use on patients' attitudes and self-care behaviors in a low-income, racially and ethnically diverse sample of patients with Type 2 Diabetes (T2DM).

METHODS: 406 patients with T2DM were enrolled in a randomized trial evaluating a health literacy intervention for diabetes care at 10 Tennessee Department of Health safety net clinics. At enrollment, data on patient characteristics and clinical information were collected via self-report and from medical records. Depressive symptoms were assessed with the Center for Epidemiological Studies Depression Scale (CES-D 20, range 0–60), with a score of ≥ 16 indicating possible depression. Patients were considered to be on an antidepressant if their medication list included an SSRI, SNRI, TCA, or atypical antidepressant. Patient self-care behaviors and attitudes were assessed with these

validated scales: Perceived Diabetes Self-Management Scale (PDSMS, range 8–40); Diabetes Treatment Satisfaction Questionnaire (DTSQ, range 0–36), Summary of Diabetes Self-Care Activities (SDSCA) and Personal Diabetes Questionnaire (PDQ); and Adherence to Refills and Medications Scale (ARMS, range 12–48, higher scores signify non-adherence). We performed one-way ANOVA tests between patient-reported attitudes and behaviors and the presence of possible depression and/or antidepressant use. We then performed adjusted regression analyses examining the relationship between each behavioral outcome and depression, antidepressant use, study status, age, gender, ethnicity, education level, duration of diabetes and interaction between depression and antidepressant use.

RESULTS: The sample was on average 51 years old (SD 9.6), 61 % were female, 18 % were African American, and 24 % were Latino. Mean education was 11.1 years (SD 3.4). Most reported no health insurance (88 %) and annual household incomes <\$20,000 (83 %). Mean A1C was 9.2 (SD 2.1). The majority (53 %) had CES-D scores >16 . Only 18 % were prescribed an antidepressant. The relationships between possible depression, antidepressant use, and patients' attitudes and behaviors are seen in the Table. Patients on an antidepressant without possible depression had the highest reported self-efficacy. In adjusted analyses, patients with possible depression had less medication adherence, lower self-efficacy, and decreased treatment satisfaction. No significant differences were seen in diet and exercise adherence, blood glucose monitoring, foot care, or glycemic control (A1C). There was no significant interaction between depression status and antidepressant use in any of the models.

CONCLUSIONS: The presence of possible depression negatively impacts self-efficacy, treatment satisfaction, and medication adherence. In this study, antidepressant use was only present in 18 % of the population despite a high rate of depressive symptoms, and use was not significantly associated with most outcomes. Treatment of depression may be important in improving diabetes related self-care behaviors; however additional research is needed on the optimal use of antidepressants to improve outcomes.

Depressive Symptoms	Absent (CES-D <16)		Present (CES-D ≥ 16)		P value	Adjusted P value
Antidepressant Use	No (n=173)	Yes (n=22)	No (n=160)	Yes (n=51)		
Treatment Satisfaction, DTSQ Score	29.73 (5.42)	26.77 (6.85)	27.35 (6.75)	25.88 (8.10)	0.0002	0.0023
Medication Adherence, ARMS Score	16.72 (3.15)	17.95 (3.48)	18.07 (4.08)	18.90 (4.09)	0.0003	0.004
Self-Efficacy, PDSMS Score	25.82 (5.58)	27.13 (6.17)	23.44 (5.51)	23.23 (6.05)	0.0001	0.0002

RELATIONSHIP BETWEEN LOCAL AREA UNEMPLOYMENT AND PREVENTABLE HOSPITALIZATIONS Edwin Wong¹; Paul Hebert; Susan Hernandez²; Adam Batten¹; Philip W. Sylling¹; Stephan D. Fihn³; Chuan-Fen Liu¹. ¹Dept of Veterans Affairs, Seattle, WA; ²University of Washington, Seattle, WA; ³Dept of Veterans Affairs, Seattle, WA. (*Tracking ID #1938277*)

BACKGROUND: Comprised of over 900 facilities nationwide, the Veterans Health Administration Affairs (VHA) provided care to over 5 million veterans in fiscal year (FY) 2012. Veterans with service connected disabilities or financial means below national thresholds receive higher priority. Prior studies have found greater utilization of VA outpatient health services among veterans residing in areas with higher local unemployment. We sought to determine whether local area unemployment among veterans enrolled in VA was associated with hospitalization for ambulatory care sensitive conditions (ACSCs), defined as 14 medical conditions for which outcomes are thought

to be modifiable with optimal outpatient care. We also examined whether the relationship between local unemployment and ACSC hospitalization differed by race/ethnicity.

METHODS: Using VA administrative data from FY2010 and FY2011, we identified a random sample of 437,630 veterans using VA primary care services and responded to the national VA Survey of Healthcare Experiences of Patients (SHEP). Using VA and Medicare inpatient encounter records, we constructed a binary measure indicating whether veterans were hospitalized for any ACSC in a VA or FFS Medicare facility during the 12 months prior to completion of the SHEP. Local area unemployment rates were defined as the 12-month average in clinic' VA planning sector, the smallest unit of geography used by VA. We used Chamberlain's random effects probit model, to address unobserved sector-level heterogeneity, while controlling for patient demographics, behavioral characteristics and health status. We stratified analyses by age group (under 65 and 65+) to account for potential differences due to Medicare eligibility.

RESULTS: In the under age 65 group, 1.2 %, 1.9 % and 1.5 % of white, black and other race veterans were hospitalized for ACSCs, respectively. Among the age 65+ group, 4.5 %, 5.3 % and 4.5 % of white, black and other race veterans were hospitalized for ACSCs, respectively. In adjusted analyses, local area unemployment rates were not associated with ACSC hospitalization among under age 65 veterans. For age 65+ veterans, a one percentage point increase in the local area unemployment rate was associated with a 9.8 % ($p=0.022$), 11.8 % ($p=0.003$) and 10.3 % ($p=0.025$) increase in the probability of ACSC hospitalization.

CONCLUSIONS: Higher local area unemployment rates were associated with a higher likelihood of ACSC hospitalization among age 65+ veterans of all races. Our findings suggest that assessment of hospital quality should also consider the context of the local economy.

RELATIONSHIP BETWEEN OBESITY AND COMORBIDITIES AND WEIGHT LOSS MOTIVATION Stephanie A. Rose¹; Sarah Schuetz¹; Chrisanthi Masero¹; Dominique Zephyr²; Kevin Real³; Kelly H. Webber⁴. ¹University of Kentucky, Lexington, KY; ²University of Kentucky, Lexington, KY; ³University of Kentucky, Lexington, KY; ⁴University of Kentucky, Lexington, KY. (Tracking ID #1940277)

BACKGROUND: Physicians perceive obese patients and those with obesity-related comorbidities as unmotivated and unable to lose weight, and cite these as obstacles to counsel patients regarding weight loss. Greater autonomous (internal), as opposed to controlled (external) motivation (AM vs. CM) is correlated with increased weight loss success. We evaluated the relationship between weight loss motivation and obesity severity and related comorbidities. We hypothesized that higher BMI and greater number of comorbidities (COM) would be associated with higher AM and lower CM to lose weight.

METHODS: Patients and providers in a university-based internal medicine clinic were enrolled in a six-month lifestyle intervention aimed at improving patient outcomes and patient and provider self-efficacy in obesity. Baseline data included the Treatment Self-Regulation Questionnaire to assess motivation, height, weight, and obesity-related comorbidities (HTN, hyperlipidemia, DM, and CV disease). A one-way ANOVA was performed to assess the relationships between BMI and AM/CM and COM and AM/CM.

RESULTS: 65 patients completed the survey (33 obesity class III (BMI \geq 40 kg/m²), 12 class II (BMI 35–39.9), 20 class I (BMI 30–34.9)). Mean AM was 5.53, (1 (low) to 7 (high)) (Class III=5.49, II=5.63, I=5.52) and mean CM was 2.20 (1 (low) to 7 (high)) (Class III=2.34, II=2.17, I=2.15). AM and CM did not differ significantly across BMI categories (AM: $F=0.06$, $p=0.94$ and CM: $F=0.21$, $p=0.81$). Nineteen patients had 0–1, 17 had 2, and 28 had 3 or 4 COM related to obesity. Mean AM for 0–1 COM=5.39, 2 COM=6.02, 3–4 COM=5.34 and mean CM for 0–1 COM=2.23, 2 COM=2.34, 3–4 COM=2.09. Increasing number of COM did not have a significant association with AM or CM (AM: $F=2.00$, $p=0.14$; CM: $F=0.30$, $p=0.74$).

CONCLUSIONS: Neither increasing BMI nor increasing number of COM was correlated with increasing AM or decreasing CM. However, we found consistently high AM and consistently low CM among all BMI categories and all numbers of COM. Our findings suggest that all classes of obese patients with differing numbers of COM are consistently motivated to lose weight. Further work is needed to assess the link between increasing BMI and increasing number of COM and associated motivation. Physicians should address weight loss with all patients with all levels of obesity and its related comorbidities.

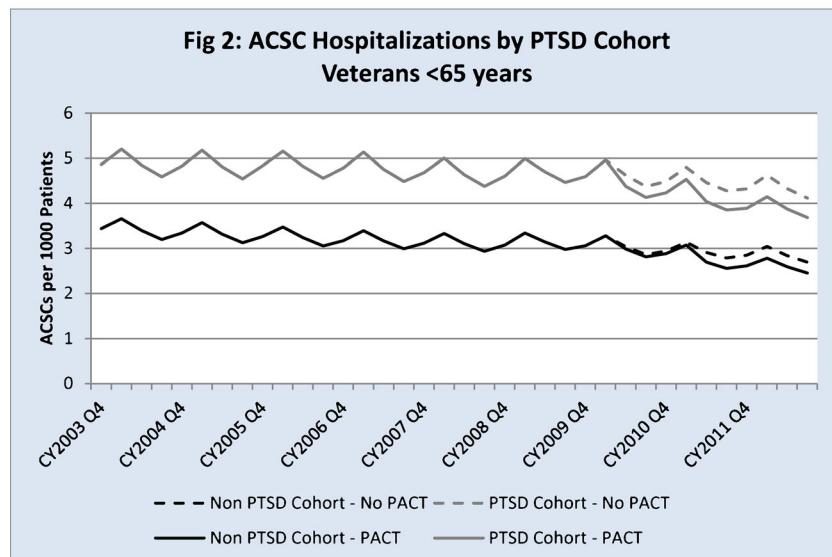

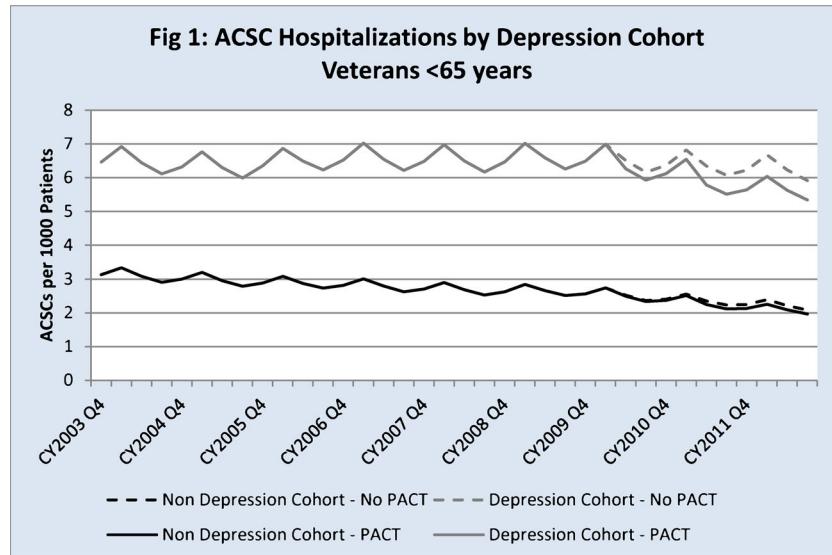

RELATIONSHIP OF MENTAL ILLNESS AND AMBULATORY CARE SENSITIVE CONDITION (ACSC)-RELATED HOSPITALIZATIONS AMONG VETERANS SEEN IN VA PRIMARY CARE Ranak Trivedi^{1,2}; Philip W. Sylling²; Edwin Wong²; Chuan-Fen Liu²; Paul Hebert²; Dan Kivlahan²; Edward P. Post²; Andrew Pomerantz²; Stephan D. Fihn³; Karin M. Nelson². ¹Dept of Veterans Affairs, Palo Alto, CA; ²Dept of Veterans Affairs, Seattle, WA; ³Dept. of Veterans Affairs, Seattle, WA. (Tracking ID #1938340)

BACKGROUND: In previous studies, Veterans with a mental health condition had higher hospitalization rates for ambulatory care sensitive conditions (ACSCs) compared to those without a mental health condition. ACSCs are medical conditions thought to be the most sensitive to the receipt of high quality primary care. The Veterans' Health Administration (VHA) has had an established program for integrated mental health services within Primary Care and implemented a patient centered medical home model, termed Patient Aligned Care Teams (PACT), in April 2010. We assessed ACSCs among cohorts of Veterans with depression and post-traumatic stress disorder (PTSD) before and after PACT to determine the influence of PACT on the rate of ACSC-related hospitalizations.

METHODS: We examined VHA's corporate data warehouse to identify Veterans who were seen in VHA primary care from 2003-Quarter 4(Q4) to 2012-Q3. ICD9 codes were used to determine a diagnosis of depression or PTSD. To account for temporal trends, facility-cohort level trends for hospitalization were modeled from 2003-Q4 to 2012-Q3. We defined facility-cohort-level ACSC rate as the total number of ACSC-related hospitalizations among Veterans with each diagnosis assigned to a clinic divided by the number of clinic patients with each diagnosis. We compared changes in ACSC hospitalizations after PACT among Veterans with PTSD or depression to Veterans at each clinic without a diagnosis of that mental illness. Changes in ACSC rates were estimated using interrupted time series analyses with the unit of observation set at the facility-cohort-quarter level. Initial and medium-term changes in ACSCs were measured using PACT indicators corresponding to 4/1/2010 (2010-Q2) and 4/1/2011 (2011-Q2). Models were adjusted for seasonality, secular trends in hospitalizations, patient age, sex, health risk, facility size, and facility area economic climate. Regression models were estimated using random effects Poisson models, which allowed intercept and time trend parameters to differ by facility and cohort. We calculated changes in ACSC hospitalizations as the difference between the observed rate of admissions and the predicted rate of admissions that would have occurred had PACT not been implemented. Due to significant utilization of non-VHA care for Veterans \geq 65, we estimated separate models for Veterans under and over 65 years of age. Models for PTSD and depression cohorts were performed separately.

RESULTS: 8,068,030 Veterans were included in this study. Veterans with depression had higher ACSC hospitalization rates (5.34 % for <65 y and 16.19 % for \geq 65 y) compared with Veterans without a diagnosis of depression (2.68 % for <65 y and 4.48 % for \geq 65 y). Likewise, ACSC rates for patients with PTSD (4.59 % for <65 y and 9.95 % for \geq 65 y) were higher than for those without PTSD (3.10 % for <65 y and 5.04 % for \geq 65 y). After PACT was implemented, Veterans with depression had a significantly lower ACSC-hospitalization rate than projected (with a decrease by 9.74 % and 8.77 % for Veterans <65 y and \geq 65 y, respectively). This compared to a 5.77 % reduction among non-depressed cohort <65 y (Fig 1) and a 2.28 % increase among non-depressed Veterans \geq 65 y. Veterans <65 y with PTSD had 10.57 % fewer ACSC hospitalizations compared to projected trend (Fig 2), while Veterans with PTSD \geq 65 had a 9.55 % reduction.

CONCLUSIONS: Rates of ACSC admission for Veterans with depression or PTSD are high. Since the inception of PACT, Veterans with either depression or PTSD have shown significant decreases in ACSC-related hospitalizations, especially among those <65 y of age.

RESIDENT BINGE DRINKING: PREVALENCE AND IMPLICATIONS FOR PATIENT CARE Magdalena Greene¹; Aaron Johnson²; J. Paul Seale²; George A. Tindol³; Kristy B. Le¹; David P. Miller¹. ¹Wake Forest Baptist Health, Winston-Salem, NC; ²Medical Center of Central Georgia, Macon, GA; ³Memorial Health University Physicians, Savannah, GA. (*Tracking ID #19363II*)

BACKGROUND: According to the National Institute on Alcohol Abuse and Alcoholism (NIAAA), approximately one-fourth of American adults engage in

binge drinking (consuming more than three or four standard drinks in one day), with highest rates among 18–34 year olds. Given this high prevalence of binge drinking, the United States Preventive Services Task Force recommends that primary care physicians screen all adults for hazardous drinking and perform a brief behavioral counseling intervention when at-risk drinking is identified. Prior studies have found that physicians who are obese or smoke are less likely to counsel patients on these respective topics; however, it is unknown how many resident physicians binge drink or whether personal binge

drinking affects the likelihood they will screen and intervene with hazardous drinkers.

METHODS: To determine the prevalence of at-risk drinking and its effect on screening and interventions, we surveyed all internal medicine residents at two academic medical centers in the Southeast. The confidential survey included items about personal alcohol consumption, residents' current practices with screening and intervening for hazardous drinking, and attitudes and beliefs about addressing substance misuse. We defined at-risk drinking according to the NIAAA definition: consuming more than three standard drinks for women or more than four standard drinks for men.

RESULTS: A total of 103 of 141 residents completed the survey (response rate 73%). Over half of residents (57/103 or 55%) reported binge drinking at least once in the prior year. Only 38% of residents who engaged in binge drinking felt confident they could identify at-risk drinking in their patients, compared to 65% of residents who did not binge drink ($p<0.01$). When residents did identify at-risk drinking in their patients, fewer residents who engaged in binge drinking advised patients to cut down or quit compared to residents who did not binge drink, but the difference was not statistically significant (63% vs. 74%, $p=0.25$). Regardless of whether residents engaged in binge drinking or not, few residents felt they had been successful helping patients cut down or quit alcohol in the past (14% vs. 28%, $p=0.08$).

CONCLUSIONS: At-risk drinking is very common among internal medicine residents, most of who are in the age cohort with the highest rates of binge drinking. Residents who binge drink are less confident they can identify hazardous alcohol use in their patients, and those residents may be less likely to advise patients to cut down or quit. Regardless of personal drinking history, most residents lack confidence they can help patients reduce their alcohol use. To help residents identify and successfully intervene with the one-fourth of Americans who are at-risk drinkers, there is a great need for additional training. Such training should also address the high prevalence of at-risk drinking among medical residents.

RESIDENT BURNOUT: IDENTIFICATION AND RAMIFICATIONS Kate Jennings^{1,2}; Ravi K. Gopal^{1,2}; Chad Stickrath^{1,2}. ¹Veterans Affairs Administration, Denver, CO; ²University of Colorado Denver School of Medicine, Aurora, CO. (Tracking ID #1939602)

BACKGROUND: Burnout is a response to work related stress characterized by depersonalization, emotional exhaustion and a sense of loss of personal efficacy. Burnout affects 30–60% of all physicians and 67% of internal medicine residents. Currently, physician burnout is assessed by self-report. No prior study has sought to objectively identify burnout. The objectives of this study were to: 1) generate a list of observable behaviors that may aid in the identification of burned out medicine residents and, 2) identify behaviors of burned out residents that may compromise patient care.

METHODS: Internal medicine clinician educators at the University of Colorado were asked to describe behaviors that burned out residents might demonstrate on rounds. These responses were used to develop items for inclusion in an annual internal medicine resident survey. The survey questions asked residents to identify specific behaviors exhibited by burned out residents during direct patient care and while participating on medicine rounds.

RESULTS: There were 166 residents invited to complete the survey and 108 residents participated (response rate 65.1%). Among 16 potential behaviors that burned out residents display on rounds, 88.9% of residents selected at least one behavior (average number of behaviors selected 5.8). Rounding behaviors that subjects felt may signal when a resident is burned out include: leaving the room before completion of team discussion (44.9%); not knowing the recommendations of consultants (31.5%); not knowing the recommendations of ancillary staff (34.8%); and frequently interrupting the presenter (23.6%) or patient (34.8%). When evaluating 15 potential behaviors of burned out residents that may impact patient care, 82.4% of residents identified at least one behavior (average number of behaviors identified 3.8). Burnout behavior that may result in patient harm include, poor hand-offs (61.5%); not “tucking” patients prior to shift change (61.5%); incomplete physical exams (44.8%); cursory medication reconciliations (24.0%); and neglect of daily conferences (75.0%) and medical student education (70.8%).

CONCLUSIONS: Burned out residents display behaviors that can be observed while on rounds. In addition, burned out residents may engage in behaviors that can

adversely affect patient care. Clinician educators and leaders may be able to utilize these behaviors to identify residents who are burned out and ensure that areas of potential patient harm are monitored by other members of the care team.

RESIDENT PERCEPTIONS OF TEAM BASED CARE IN THEIR CONTINUITY CLINIC Tacara N. Soones²; Katherine Julian¹; Bridget O'Brien¹. ¹University of California- San Francisco, San Francisco, CA; ²University of California- San Francisco, San Francisco, CA. (Tracking ID #1927140)

BACKGROUND: Interprofessional teams are becoming an integral part of addressing our society's complex healthcare needs. Yet, the structure and goals of residency can make it difficult for physicians in training to learn to work within ambulatory teams to enhance their current and future practice. Furthermore, little is known about residents' experiences working in continuity clinic teams and the impact of these teams on their education.

METHODS: Eleven focus groups were conducted with categorical and primary care internal medicine residents at the University of California San Francisco's three continuity clinic sites: 3 at a veteran's hospital, 4 at a safety net hospital, and 4 at a university-based clinic. Focus groups were conducted during regularly scheduled conference times and included PGY1, PGY2, and PGY3 residents depending on the clinic site. A total of 78 residents participated and focus groups were conducted until thematic saturation was reached. A general inductive approach was used to analyze themes.

RESULTS: As residents identified factors that aligned with the 4 domains in Reeves' model of interprofessional collaboration (relational, processual, organizational and contextual), this framework was employed to organize study results. Residents with positive perceptions of team based care, defined as those who expressed feeling like they were part of a team or gave positive examples of interprofessional collaboration, were more likely to cite positive relational factors (stable relationships with their team members and knowledge of team member roles), processual factors (useful huddles), and contextual factors (culture of shared responsibility). Residents with negative perceptions, defined as those who did not feel like they were members of a team, were more likely to cite negative relational factors (high team member turnover and lack of role clarity), processual factors (poor communication through the electronic health record and insufficient clinic time over the course of residency), organizational factors (limited staffing resources) and contextual factors (a culture of the resident being responsible for all patient care). Residents with positive perceptions were more likely to be third year residents or have clinic at the Veteran's Affairs clinic site. Residents believed the interprofessional model provided more patient support and allowed team members to operate at their highest level of training, but rarely believed working in teams was intrinsically of high educational value.

CONCLUSIONS: Residents' perceptions of the utility of their interprofessional teams were most affected by their integration into a stable team structure within the continuity clinic site and the opportunity to leverage professional relationships to coordinate patient care. While resident continuity clinics have innate scheduling challenges, high functioning teams can emerge when resources are invested in relational and processual elements of team development.

RESIDENT PRIORITIES IN AMBULATORY TRAINING: NEED FOR IMPROVED EDUCATION AND TRANSITION TO PATIENT-CENTERED MEDICAL HOME Theodore Long¹; Ian Halim²; Krisda H. Chaiyachati¹; Bradley G. Richards¹; Peter Moyer¹; John P. Moriarty¹. ¹Yale University School of Medicine, New Haven, CT; ²Harvard Extension School, Boston, MA. (Tracking ID #1923616)

BACKGROUND: As patients now receive the majority of their chronic disease and preventive care in the ambulatory setting, medical education in ambulatory settings has evolved to begin to address these demands. However, graduating internal medicine residents continue to feel uncomfortable managing common chronic conditions. Studies have shown that inadequate infrastructure and a lack of a team-based system are often prevalent in ambulatory resident training, but there is a paucity of data regarding the perspectives of residents on their priorities for ambulatory education. Especially as the patient-centered medical home is being viewed as a potential intervention to improve the infrastructure and teamwork environment in ambulatory training, elucidating and understanding the priorities of internal medicine

residents relating to ambulatory training will help align their priorities and the health system's goals.

METHODS: We sent an anonymous online survey to all Traditional Internal Medicine, Primary Care Internal Medicine, Combined Internal Medicine and Pediatric, and Pediatric residents at Yale-New Haven Hospital. A survey instrument with open-ended questions was developed from pilot interviews and existing literature targeted at examining educational priorities and structural components of ambulatory training. Two members of our interdisciplinary research team independently applied codes to the responses. We developed our code structure based on grounded theory, applying a systematic and inductive approach to generate insights from the responses of the residents. The research team then met to resolve disagreement and reach consensus on the final coding structure. The final codes were arranged into five main themes.

RESULTS: We received 43 completed surveys (22 % response rate). The responses were grouped into five main themes: inadequate resources, balance of inpatient versus outpatient training, need for improved role clarity and team-based care, issues with patient continuity and scheduling, and a desire for increased didactics with an outpatient emphasis. Specifically focusing on priorities in medical education, residents described wanting further didactic teaching during ambulatory blocks, as well as feeling challenged to meet both inpatient and continuity clinic responsibilities while on inpatient blocks. With respect to the structural aspects of ambulatory training, residents noted several areas needing improvement that are consistent with moving toward a patient-centered medical home: need for role clarity, improved continuity, and a need for establishing team-based care.

CONCLUSIONS: Internal Medicine and Pediatric residents want dedicated outpatient didactics and training that are more evenly balanced and prioritized with respect to inpatient responsibilities. They also identify several components of the patient-centered medical home (improved continuity, role clarity, team-based care) as important structural changes when redesigning ambulatory training.

RESIDENT USE OF A READMISSIONS PREDICTION MODEL DECREASES TIME TO FOLLOW-UP AND IMPACTS TRUE READMISSION RATES

Ryan D. Schulteis^{1,2}; Thomas W. LeBlanc²; Eugene Z. Oddone²; David Simel^{1,2}. ¹Durham VA Medical Center, Durham, NC; ²Duke University Medical Center, Durham, NC. (*Tracking ID #1924494*)

BACKGROUND: Validated readmission prediction tools could allow targeted interventions towards patients at the highest risk of rehospitalization. We evaluated the validity of a previously derived readmission prediction tool and examined the relationship between a patient's predicted readmission rate and time to the first scheduled follow-up visit. Most physicians believe that early follow-up prevents readmissions, so we also quantified the impact of the timing of scheduled post-hospitalization clinic visits on a patient's probability of readmission within 30 days of hospital discharge.

METHODS: At hospital discharge, resident physicians used a calculator to prospectively estimate and record the predicted readmission rate (within 30 days of discharge). In addition to the predicted readmission rates, actual 30-day readmission rates and the time from discharge to the first scheduled follow-up visit were obtained from the electronic medical record.

RESULTS: Over 2 years, discharge summaries from 4568 distinct discharged patients were retrieved. The mean patient age was 66 years, 95 % were male Veterans, and 20 % of patients were readmitted within 30 days. The readmission prediction tool c-statistic, a measure of discriminatory power, was 0.60 ($p<0.001$). The predicted readmission rate was significantly correlated with the median time to scheduled follow-up; for every 9.6 % increase in the predicted probability of readmission, patients were scheduled for follow-up 1 day sooner ($p<0.001$, Figure 1). In all possible pairs of patients matched for the same predicted probability of readmission ($n=546426$ pairs), the patient scheduled for an early follow-up visit was 37 % more likely to be readmitted ($p<0.001$) than the patient scheduled for later follow-up (Figure 2).

CONCLUSIONS: Patients with higher predicted rates of readmission were scheduled for earlier follow-up visits. Being scheduled for earlier rather than later follow-up was not associated with a lower risk of readmission. Instead, patients scheduled for early follow-up have a substantially higher risk of readmission that may account for over 1/3 of readmissions.

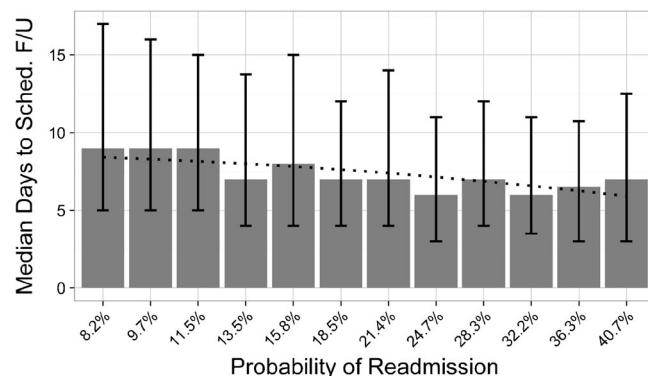

Figure 1: Time to follow-up decreases as the probability of readmission increases. The probability of readmission is inversely correlated with the scheduled time to follow-up. Error bars represent the interquartile range for that group.

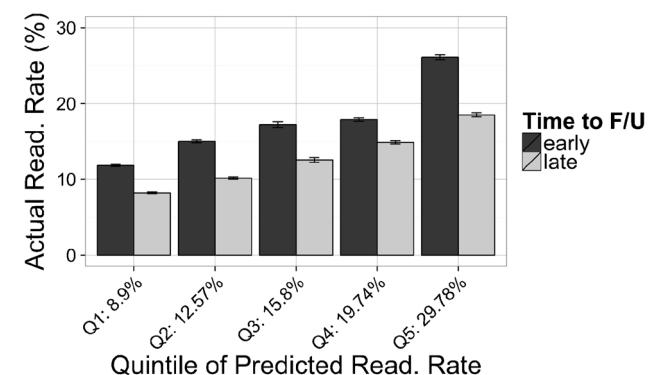

Figure 2: Readmission rates are increased in patients scheduled for early follow-up. Within groups of patients with similar predicted readmission rates, we evaluated all possible pairs of patients. Within each pair, the patient scheduled for an earlier follow-up appointment was designated "early" and the other designated "late". In every group, the patient seen earlier was more likely to be readmitted than the patient seen later. The readmission rate in those seen early was 37 % higher than those seen later (relative risk 1.37, 95 % CI 1.35 to 1.39).

RESIDENTIAL CARE FACILITIES' ABILITY TO COMMUNICATE WITH HOSPITALS

Robert Burke^{1,2}; Christine D. Jones²; Cari Levy⁴; Adit Ginde³. ¹Denver VA Medical Center, Denver, CO; ²University of Colorado, Denver, CO; ³University of Colorado, Denver, CO; ⁴University of Colorado, Denver, CO. (*Tracking ID #1940104*)

BACKGROUND: Older adults in residential care facilities (RCFs) are vulnerable to a cycle of hospitalization and institutionalization leading to substantial decrements in their health and functional ability. Prior research indicates a major barrier hospitals and care facilities experience in providing adequate care to these patients is incomplete transfer of information between the two sites. Improved information exchange between facilities and hospitals may decrease errors and potentially improve patient outcomes. We sought to understand the ability of RCFs to generate

computerized discharge or transfer summaries, and to electronically exchange information with hospitals.

METHODS: Data were drawn from the 2010 National Survey of Residential Care Facilities (NSRCF), a nationally-representative probability sample survey of United States RCFs conducted by the Center for Disease Control's National Center for Health Statistics ($n=2302$). Eligible facilities had to be licensed, registered, or otherwise regulated by the state, have four or more licensed beds with at least one resident living in their facility at the time of the survey, and at a minimum provide 24 h a day supervision and personal care to the residents, in addition to two meals per day. Facilities that serve mentally ill or developmentally disabled populations were excluded. We compared facilities with and without these capabilities (as reported by the facility director) using Chi-Square tests and multiple logistic regression.

RESULTS: 21.4 % of facilities ($n=493$) could produce computerized discharge and transfer summaries; 5.5 % ($n=127$) were able to exchange information electronically with hospitals. Bivariate and multivariate analysis resulted in similar findings: larger (OR 1.71, 95 % CI 1.12–2.61 versus 10 beds or less), more expensive (1.63, 1.15–2.31 versus lowest cost), non-profit and government facilities (OR 1.63, 1.17–2.25 versus for-profit), and facilities with skilled nursing services (1.52, 1.15–2.04 versus those without) were significantly more likely to be able to generate computerized discharge and transfer summaries; RCFs with longer waitlists (2.31, 1.29–4.15 versus shorter waitlists) and skilled nursing services (1.92, 1.18–3.13) were more likely to have electronic information exchange capabilities.

CONCLUSIONS: Few RCFs have advanced capabilities for information exchange with hospitals. These findings have substantial patient safety implications given more than one-third of RCF residents visited the ED in the year prior to the survey, and nearly a quarter were hospitalized. Enhancing and standardizing information transfer capabilities may lead to better outcomes for this high-risk population of residents, but substantial financial, legal, and technological barriers to implementation exist.

RESIDENTS' PERSPECTIVES ON THE VALUE OF iPADS AND POINT-OF-CARE RESOURCES IN THE DELIVERY OF QUALITY CARE AND EVIDENCE-BASED MEDICINE AT THE BEDSIDE Alfredo Sardinas; Kathleen V. Carter; Alexander Bullen Clarke; James F. Hanley. UTHSCSA, Harlingen, TX. (Tracking ID #1941613)

BACKGROUND: There has been an evolutionary change in the delivery of care with the advent of mobile devices. Tablets and smartphones have brought both the medical record and point-of-care (POC) information resources to the patient (bedside or clinic). The utility of this change requires an assessment of both the platform and the resources. It was reported in one small study that only 45 % of medicine-based residents surveyed agreed that iPads facilitated better patient care. There is very little information on the utility of mobile POC information resources, specifically on preference. Although, it is presumed that POC resources will bring the best evidence for making clinical decisions at the bedside there are other factors such as ease of use, accuracy, quantity, current information and timely results that are important when selecting a clinical decision support tool. These factors contribute to a physician's overall satisfaction with the product. As part of our resident-led evidenced-based curriculum, we questioned our resident perspective on the value of iPads for patient care. We also examined their selection of POC information resources and if that determination was dependent upon the type of clinical question being answered. Finally, during this study the ACP released Smart Medicine, a POC tool. This had face validity, linked easily to the evidence, and was free to its members. We compared Smart Medicine to other information resources to answer clinical questions that were raised during check-in rounds or morning report.

METHODS: iPads were issued to all residents, with access to EMRs and POC resources. At 6 months, residents were surveyed on both the clinical and educational utility of their iPads and their usage of POC resources to answer clinical questions. Subsequently, residents were asked to answer eight clinical questions comparing Smart Medicine to other POC resources. Residents then chose the resource which performed best in the following categories: accuracy, quantity, current information, timeliness, ease-of-use and overall satisfaction.

RESULTS: Residents reported that the iPad was used frequently on rounds (94 %). All residents reported that using the iPad increased efficiency (100 %) and 87 % agreed it facilitated better patient care. UpToDate was the preferred POC resource, but others were often used for specific types of clinical questions. UpToDate was the preferred comparator to Smart Medicine (88.7 %). For accuracy of information, Smart Medicine 19.3 % vs. other resources at 53.2 %; quantity of information, Smart Medicine 12.9 % vs. other resources 64.5 %; current information, Smart Medicine 22.5 % vs. other resources 51.6 %; speed of resource, Smart Medicine 17.7 % vs.

other resources 64.5 %; usability, Smart Medicine 21.0 % vs. other resources 59.7 %; and overall satisfaction, Smart Medicine 22.5 % vs. other resources at 51.6 %.

CONCLUSIONS: Our residents felt that their iPads improved clinical efficiency. The iPads facilitated accessing the EMR and answering clinical questions. This was aided by a favorable IT environment that was compatible with EMR and POC apps. There was a strong preference for UpToDate, but other POC resources were selected. Smart Medicine, despite its appealing characteristics, was not well received when compared to other resources. Feedback indicated that this was due to several factors including familiarity with certain resources (cognitive inertia), technical problems (usability issues), and the need for a search engine leading to a broader database of clinical information. Mobile devices and POC resources are interdependent and together show great promise as both educational and clinical tools. Challenges will arise with integration and teaching their use to facilitate clinical practices. The assessment of POC resources will require a more disciplined approach to understanding their value and limitations. High quality clinical care requires that best practices for implementation be developed for successful integration of mobile technology.

RESULTS OF POPULATION-BASED, PROACTIVE OUTREACH TO NON-TREATMENT SEEKING PRIMARY CARE PATIENTS AT HIGH RISK FOR AUD IN THE CHOICE TRIAL Katharine Bradley¹; Gwen T. Lapham¹; Julie E. Richards¹; Joseph Merrill⁴; Emily Williams²; Amy K. Lee¹; Erika Holden¹; Laura Chavez³; Daniel Kivlahan⁵. ¹Group Health Research Institute, Seattle, WA; ²VA Puget Sound HSR&D COIN, Seattle, WA; ³Department of Health Services University of Washington, Seattle, WA; ⁴Department of Medicine, University of Washington, Seattle, WA; ⁵Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA. (Tracking ID #1938738)

BACKGROUND: Clinicians often fail to recognize alcohol use disorders (AUDs), and most patients with AUDs never receive treatment. Population-based, proactive outreach and chronic care management may be a way to engage primary care (PC) patients at high risk for AUD in alcohol-related care. However, little is known about the needs of patients with alcohol misuse who might be recruited by such an approach. We describe results of proactive outreach to PC patients at high risk for AUD for the CHOICE trial—a randomized controlled “encouragement” trial that offers intervention patients alcohol-related collaborative care from a chronic care nurse. Specifically, we report the proportion of potentially eligible patients enrolled over the first 2 years, how they compare to potentially eligible patients who were not enrolled, and describe the AUD severity and readiness to change of enrolled patients.

METHODS: The study sample was recruited from 3 VA PC clinics. Patients were potentially eligible if they screened positive for alcohol misuse (AUDIT-C ≥ 3 women, ≥ 4 men) and they were 21–75 years old. Patients were eligible if they: 1) reported frequent heavy episodic drinking at phone screening (≥ 4 and ≥ 5 drinks for women and men respectively, $\geq 2 \times$ weekly on average); 2) were not in AUD treatment in the prior 90 days, 3) were medically and psychiatrically stable based on chart review (e.g. no acute psychosis) and 4) planned to continue receiving PC from the VA. Baseline interviews assessed: the prevalence and severity of DSM-5 AUD; the number of common mental health (MH) conditions (0–5 based on validated measures for depression, generalized anxiety, panic, PTSD, or drug use disorders); and patient-reported importance, readiness, and confidence in changing their drinking (based on readiness rulers).

RESULTS: Of 2,702 potentially eligible patients, 375 (14 %) patients were eligible at phone screening and agreed to attend baseline enrollment interviews. Of those, 219 (58 %) consented and enrolled in the trial (29 % declined participation; 12 % were ineligible e.g. had decreased drinking, planned to move, etc.). Compared to the potentially eligible patients who did not enroll, those who enrolled were more likely to be men (90 % vs. 85 %; $p=0.05$) and had higher AUDIT-C scores (7.2 vs. 6.5 points, $p<0.0001$). The first 210 enrolled patients whose baseline interview data were available for analysis at this time represented range of severity and complexity: 88 % met criteria for DSM-5 AUD (31 %, 27 %, and 30 %, with mild, moderate, and severe, respectively); and 64 % had one or more MH conditions (24 %, 13 %, and 27 % had 1, 2, and 3 or more of the 5 conditions assessed, respectively). About three quarters (73 %) of enrolled patients noted that changing their drinking was somewhat to very important, 72 % reported they were somewhat to very ready to change, and 80 % were somewhat to very confident that they could change their drinking.

CONCLUSIONS: Proactive outreach using population-based alcohol screening engages patients with a range of alcohol misuse severity, MH complexity and readiness to change alcohol use. Programs that engage patients in this way will need to be prepared to offer care that addresses a range of AUD severity, psychiatric comorbidity and readiness to change their drinking.

REVISITING DISPARITIES IN QUALITY OF CARE AMONG U.S. ADULTS WITH DIABETES IN THE ERA OF INDIVIDUALIZED TARGETS, NHANES 2005–2010 Neda Laiteerapong; Paige Fairchild; Chia-Hung Chou; Marshall Chin; Elbert S. Huang, University of Chicago, Chicago, IL. (Tracking ID #1940849)

BACKGROUND: Health disparities in diabetes care have been traditionally characterized using universal goals for glycemic, blood pressure, and cholesterol control. In 2008, evidence from major diabetes trials found that intensive glycemic control may cause worse outcomes among older patients with cardiovascular disease and high comorbidity. Since the publication of these trials, diabetes guidelines have made specific recommendations for individualized glycemic goals based on age, duration of disease, and complications. These individualized goals may have important implications for assessments of disparities in diabetes quality of care because minorities differ from non-Hispanic whites on a number of variables that are the basis for individualization. We reassess disparities in diabetes care using new individualized care goals in order to determine 1) the degree to which diabetes recommendations differ by race/ethnicity and 2) if diabetes disparities are altered with new care goals.

METHODS: We analyzed a nationally-representative sample of non-Hispanic whites (W), non-Hispanic blacks (B), and Mexican American/Hispanic (MA) adults with self-reported diabetes aged ≥20 years in the National Health and Nutrition Examination Survey (NHANES), 2005–2010 ($N=1840$; weighted $N=16.5$ million). Individualized glycemic goals ($A1C <6.5\%$, $<7\%$, or $<8\%$) were specified based on age (20–44, 45–64, 65–75, or >75 years), duration (≤ 10 vs. >10 years), self-reported complications, and comorbidity, defined using the weighted combined Charlson Comorbidity Index. Individualized cholesterol goals ($LDL <100$ or <70 mg/dL) were identified based on cardiovascular history. We assigned participants individualized glycemic goals and compared the proportions assigned to each individualized glycemic goal by race/ethnicity. Then we compared the proportions who had met their individualized glycemic, cholesterol, and comprehensive care goals (glycemic, cholesterol, blood pressure ($<140/80$ mmHg), and non-smoking) by race/ethnicity.

RESULTS: Blacks and Mexican Americans were younger than Whites (B: 58, MA: 55, W: 61 years, $p<.001$). Mexican Americans had fewer complications than blacks and whites (MA: 33 %, B: 47 %, W: 45 %; $p=.01$). The population-wide distribution of individualized glycemic goals differed for Mexican Americans ($p<.001$), but not blacks ($p=.55$), compared to whites. Nearly one in five (17 %) Mexican Americans should be recommended an $A1C <6.5\%$ compared to one in ten (10 %) whites and blacks; 43 % of Mexican Americans should be recommended an $A1C <7\%$ compared to 31 % of whites and 34 % of blacks. Fewer Mexican Americans (55 %, $p<.001$) and blacks (60 %, $p=.004$) had adequate individualized glycemic control compared to whites (70 %). In contrast, using a universal glycemic target of $<7\%$, Mexican Americans (46 %, $p=.01$), but not blacks (50 %, $p=.12$) were less likely to have adequate control, compared to whites (56 %). Blacks were less likely to have comprehensive individualized quality of care compared to whites (4 % vs. 17 %, $p <.001$), a difference which approached significance for Mexican Americans (10 %, $p=.06$).

CONCLUSIONS: Compared to universal goals, individualized goals for diabetes care actually accentuate disparities in diabetes care, especially for blacks. Individualized glycemic goals are necessary in evaluating disparities in quality of care, otherwise disparities will be underappreciated and worse diabetes outcomes will persist for blacks and Mexican Americans. Significant disparities exist in individualized glycemic, cholesterol, and comprehensive quality of care.

RISK FACTORS FOR POTENTIALLY AVOIDABLE READMISSION IN CANCER PATIENTS Jacques Donze^{1,2}; Stuart R. Lipsitz^{1,2}; Jeffrey L. Schnipper^{1,2}. ¹Brigham and Women, Boston, MA; ²Harvard Medical School, Boston, MA. (Tracking ID #1897611)

BACKGROUND: Cancer patients are particularly at risk for being readmitted within 30 days after discharge. However, many of these readmissions are either related to elective chemotherapy or are not avoidable. In order to identify the cancer patients who might benefit from more intensive discharge interventions, we aim to identify the risk factors associated with 30-day potentially avoidable readmission in cancer patients.

METHODS: We included all consecutive discharges from the oncology division of an academic tertiary medical center in Boston between July 1, 2009 and June 30, 2010. Potentially avoidable 30-day readmissions to the index hospital or two other hospitals within its network were then identified using a validated computerized algorithm based on administrative data (SQLape). We performed a multivariable

logistic regression in which the final model included variables that were found to be significantly associated with the outcome in bivariable testing.

RESULTS: Among the 2,916 patient discharges during the study period, 1,086 (37.3 %) were followed by a readmission within 30 days. Of these, 341 (31.4 % of all readmissions, 11.7 % of all discharges) were identified as being potentially avoidable. In a multivariable analysis, the following risk factors were associated with a significantly higher potentially avoidable readmission risk (Table): number of admissions in the previous 12 months, non-elective index admission, and hematological neoplasm.

CONCLUSIONS: Cancer patients have a high risk of readmissions. The main risk factors associated with 30-day potentially avoidable readmission in this population are a higher number of prior admissions, a non-elective index admission, and a hematological neoplasm. Interventions at discharge may be prioritized to the cancer patients with these risk factors.

Multivariate analysis of risk factor for 30-day potentially avoidable readmission in cancer patients *

Variable	Odds Ratio (95%CI)	P value
Length of stay, per 1 day increase	1.01 (1.00–1.02)	0.06
Elective index admission	0.45 (0.35–0.58)	<0.001†
Number of admissions in the previous 12 months	1.05 (1.02–1.08)	0.004†
Total number of medications at discharge	1.00 (0.98–1.02)	0.86
Opiate medication at discharge	1.04 (0.86–1.25)	0.70
Anticoagulation therapy at discharge	1.14 (0.93–1.41)	0.20
Elixhauser comorbidity score, per 1 unit increase	1.00 (1.00–1.01)	0.37
Congestive heart failure	1.10 (0.80–1.51)	0.57
Liver disease	1.20 (0.79–1.81)	0.40
Hematological neoplasm	1.49 (1.13–1.97)	0.005†
Metastatic neoplasm	1.04 (0.76–1.41)	0.82
Ovarian neoplasm	1.49 (0.94–2.37)	0.09
Hemoglobin, per one unit increase	1.00 (1.00–1.02)	0.82
Sodium level, per one unit increase	1.00 (0.98–1.02)	0.99

RISK FACTORS FOR RECURRENT *CLOSTRIDIUM DIFFICILE* INFECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS Abhishek Deshpande¹; Vinay Pasupuleti²; Priyaleela Thota²; Chaitanya Pant³; David D. Rolston⁴; Adrian V. Hernandez^{5,1}; Curtis J. Donskey^{6,2}; Thomas Fraser⁷. ¹Cleveland Clinic, Cleveland, OH; ²Case Western Reserve University, Cleveland, OH; ³Kansas University Medical Center, Kansas City, KS; ⁴Geisinger Medical Center, Danville, PA; ⁵Universidad Peruana de Ciencias Aplicadas, Lima, Peru; ⁶Cleveland VA Medical Center, Cleveland, OH; ⁷Cleveland Clinic, Cleveland, OH. (Tracking ID #1931651)

BACKGROUND: The risk of acquiring *Clostridium difficile* infection (CDI) during a hospital admission is estimated to be 1 in 100 patients with a 10 % risk of in-hospital death. In the past 2 decades, the prevalence of hospital-acquired CDI has more than doubled in the United States. CDI therapy is initially effective for most patients, but an estimated 20–30 % of patients develop symptomatic recurrence within 2 weeks of successful completion of therapy. While the mechanism of recurrence has not been elucidated, a variety of risk factors have been suggested. Our aim was to evaluate current evidence on the risk factors for recurrent CDI (rCDI).

METHODS: We searched MEDLINE, Web of Science, Cochrane library, and SCOPUS databases for the following search terms: CDI, risk factor, predictor, marker, relapse, recurrence and recurrent. All studies that investigated the risk factors of rCDI using multivariate methods were considered eligible. Information on assessed risk factors was collected and data were combined by means of a random-effects model. Pooled odds ratios (ORs) and 95 % CIs were calculated.

RESULTS: Of the 310 citations identified, 31 studies ($n=16,280$ patients) met the inclusion criteria. The most frequent risk factors associated with rCDI were advanced age, antimicrobial therapy and use of proton pump inhibitors (PPI). Age (per year increase) and ≥ 65 years were associated with an increased risk of rCDI (OR 1.02, 95%CI 1.01–1.02, $P<0.001$ and OR 1.63, 95%CI 1.22–2.17, $P<0.001$ respectively), as was additional non-CDI antibiotic therapy after treatment (OR 2.18, 95%CI 1.63–2.93, $P<0.00001$). Risk was also greater for patients who were prescribed fluoroquinolones before the initial occurrence of CDI (OR 1.48, 95%CI 1.19–1.83, $P=0.0004$) and patients taking a PPI during CDI treatment (OR 1.80, 95%CI 1.17–2.77, $P=0.007$).

CONCLUSIONS: Advanced age, additional antimicrobial therapy during follow up and use of PPI during CDI treatment were associated with a greater risk of developing recurrent CDI. In older patients with a history of CDI, judicious use of antibiotics and PPIs might help reduce CDI recurrence.

RISK FACTORS FOR RECURRENT SPONTANEOUS EPISTAXIS Victor Arbrich¹; Annabelle Brozek²; Timothy R. Boyle³; Steven H. Yale¹. ¹Marshfield Clinic - St. Joseph's Hospital, Marshfield, WI; ²Marshfield Clinic - St. Joseph's Hospital, Marshfield, WI; ³Marshfield Clinic - St. Joseph's Hospital, Marshfield, WI. (Tracking ID #1939670)

BACKGROUND: Epistaxis is a common medical and surgical otolaryngological condition, accounting for approximately 1 in 200 emergency room visits in the United States. Most episodes of epistaxis are self-limited and few patients seek medical attention. However, a subset of patients will experience frequent recurrent episodes which may be severe enough to warrant medical attention. Although many putative risk factors have been described for a single episode of epistaxis, it is unknown which factors are responsible for recurrent episodes. This study was designed to identify risk factors associated with spontaneous recurrent events.

METHODS: This was a retrospective case-control study assessing patients within the Marshfield Clinic system diagnosed with epistaxis between January 1st 1991 and January 1st 2011. Cases were defined as having at least two episodes of epistaxis requiring medical care separated by a minimum of 3 months within a 36-month period, whereas controls had one episode in the same time period. An episode of epistaxis consisted of a cluster of non-traumatic nosebleeds including the incident event, subsequent care, and follow-up. Controls ($n=916$) were 2:1 frequency-matched to cases ($n=458$). Episodes were manually adjudicated in the medical record. Data on demographics, social history, treatment, comorbidities, medications, lab values, and adverse outcomes were electronically and manually abstracted for each event. For controls, the second point of data collection was taken from a three-month period corresponding to a case's second epistaxis episode. Fisher's Exact Test was used in the statistical analysis to derive p-values. Odds ratios were calculated for each risk factor.

RESULTS: Males were more likely to have recurrent epistaxis compared to females (OR=1.35, 95 % CI 1.08–1.70, $p=0.0087$). A documented history of smoking was found to confer an increased risk of epistaxis recurrence (OR 1.36, 95 % CI 1.07–1.73, $p=0.0119$). Warfarin use was higher in cases compared to controls (27 % vs. 19 %, $p=0.0006$) without any appreciable difference in the level of anticoagulation when considering INR ranges <2.0, 2.0–3.0, and >3.0. No significant difference was observed between the proportions of cases and controls taking aspirin, clopidogrel, NSAIDS, or antidepressants. Also, no differences were observed between cases and controls for many common co-morbidities including hypertension, diabetes mellitus, coronary artery disease, stroke, and chronic kidney disease; however, cases were more likely than controls to have congestive heart failure (OR=1.62, 95 % CI 1.25–2.11, $p=0.0004$). Most striking was the finding that within 30 days of an epistaxis event, cases had a decreased risk of myocardial infarction (OR=0.07, 95 % CI 0.03–0.12, $p<0.0001$) and stroke (OR=0.11, 95 % CI 0.06–0.21, $p<0.0001$).

CONCLUSIONS: Risk factors for recurrent epistaxis found in this study include male gender, smoking history, warfarin use, and a history of congestive heart failure. Patients with recurrent epistaxis appear to be protected from myocardial infarction and stroke, which may be due to the continued use of antiplatelet medications in the setting of nosebleeds. The opposite may be true for patients who choose to stop such medications temporarily after developing epistaxis. These results demonstrate the importance of promoting medication compliance despite the occurrence of recurrent epistaxis to prevent major adverse cardiovascular events.

RISK PERCEPTION, SELF-EFFICACY, AND OBJECTIVE HEALTH RISK Stephanie A. Rose¹; Brett Capel¹; Bharat Kumar¹; Nicholas Jackson¹; Brittany P. Fenner¹; Chrisanthi Masero¹; Dominique Zephyr²; David Rudy¹; Kevin Real³. ¹University of Kentucky, Lexington, KY; ²University of Kentucky, Lexington, KY; ³University of Kentucky, Lexington, KY. (Tracking ID #1940365)

BACKGROUND: Risk perception and self-efficacy can predict success in health related changes. However, patients may not appropriately perceive their objective risk of disease. We aimed to evaluate the correlation between patient risk perception and self-efficacy and objective patient risk as defined by the Diabetes risk score developed by Bang et al. We hypothesized that higher levels of risk perception and self-efficacy would be associated with lower objective risk of disease.

METHODS: Patients in a university-based internal medicine clinic completed a quantitative survey assessing risk perception (RP) of developing and self-efficacy

(SE) of avoiding the development of diabetes (DM) using validated survey tools. We performed chart reviews to obtain laboratory, demographic, and anthropometric data to calculate each patient's diabetes risk score based on validated risk calculators.

RESULTS: Patients ($n=28$) were 96.4 % white, 35.7 % male, mean age 54.52 years (SD 11.92), 18 % were overweight (BMI 25–29.9 kg/m²), 39 % were obese (BMI ≥ 30), and 3 patients (10 %) had a diagnosis of DM. Of patients not already diagnosed with DM ($n=25$), mean SE for avoiding developing DM was 4.55 (SD 2.18) (range 1 low to 7 high), and mean RP of developing DM was 2.63 (SD 1.49) (range 1 low to 7 high). Mean objective health risk of developing DM was 3.33 (SD 1.98) (range 1 low to 6 high). There was a negative correlation between SE and objective risk ($r=-0.507$, $p=0.005$) and a negative correlation between RP and objective risk ($r=-0.119$, $p=0.281$).

CONCLUSIONS: Conclusions: We found a non-significant correlation between patient RP of developing DM and their actual risk; however, we observed a significant negative correlation between SE in stopping the development of the disease and a patient's objective risk. Although patient understanding of risk may promote an initial desire to improve one's health, self-efficacy or one's confidence in avoiding development of diabetes may play a more significant role in influencing a patient's actual risk of DM. Further goals include increasing sample size; assessing the correlation between RP, SE, and actual risk of developing heart disease and lung cancer; as well as developing tools to help physicians improve perceived risk and self-efficacy.

ROLES DESIRED BY CAREGIVERS OF PATIENTS WITH HEART FAILURE: IMPLICATIONS FOR CLINICIANS Robert Burke^{1,2}; Jacqueline Jones³; David Bekelman^{4,2}. ¹Denver VA Medical Center, Denver, CO; ²University of Colorado, Denver, CO; ³University of Colorado, Denver, CO; ⁴Denver VA Medical Center, Denver, CO. (Tracking ID #1940148)

BACKGROUND: Heart failure (HF) often results in significant burden to patients, their caregivers, and the health care system. A significant contributor to the morbidity and mortality associated with HF is poor adherence to self-management of the disease. Caregivers play a major role in HF management. However, few studies have assessed the roles caregivers desire in interacting with the person they care for and the health care system. Understanding these desired roles is important because doing so may lessen caregiver burden, improve the ability of patients and caregivers to manage their illness at home, and improve the efficacy of the clinicians caring for these patients leading to improved outcomes.

METHODS: Two interviewers with experience in qualitative methods conducted in-depth, semistructured, 60- to 90-minute interviews with 33 diverse patients with New York Heart Association class II to IV HF (confirmed by a cardiologist) and 20 of their family caregivers. The interviews explored specific domains including symptoms, psychosocial issues, decision-making, and the future of illness. Caregivers were identified by asking patients, "Can you think of the one person beside a healthcare provider who helps you the most with your heart condition?" We used the method of constant comparison derived from grounded theory for analysis, using participant triangulation (comparing perspectives of both patients and caregivers) to identify roles caregivers desired and those they perceived were assigned to them.

RESULTS: Caregivers desire different roles than the ones they perceive are assigned to them by the health care system and the person they care for. First, many caregivers express a desire for a role working on behalf of the health care system to carry out HF care at home, but desire more information to be able to do so. Second, most caregivers want a role that is valued when interacting with the health care system, and want to be invited to participate in interactions between the person they care for and the health care system. Third, the majority of caregivers wish for a role moderating communication between the person they care for and the health care system as they frequently observe poor bidirectional communication. Fourth, many caregivers desire a more passive role in communicating at home than the one they feel is assigned to them, and would welcome help discussing difficult topics with the person they care for.

CONCLUSIONS: This study has several important implications for clinicians caring for patients with HF who have supporting caregivers. First, many caregivers, when included in the care plan and supported with relevant information, are eager to facilitate home care for patients with HF. Second, clinicians should solicit the input of caregivers, as many caregivers feel they have important insights that may not be identified otherwise. Third, clinicians should ask patients with HF if they have a caregiver and arrange visits so the caregiver can attend. Fourth, clinicians should inquire about whether the caregiver and patient with HF are communicating about difficult topics, including goals of care, burden, and psychological adjustment to the illness, and offer help to surmount barriers in communication. These changes are may

result in more accurate assessment of patients with HF, improved management of the disease at home, and improved quality of life for the patient and caregiver.

ROUNDLY DEBATED: BUILDING BEST PRACTICES FOR ATTENDING ROUNDS AT A TEACHING HOSPITAL Nader Najafi; Bradley Monash; Michelle Mourad; Yile Ding; Marcia Glass; Gregory Burrell; James D. Harrison. UCSF, San Francisco, CA. (*Tracking ID #1938419*)

BACKGROUND: Attending rounds, defined as ward rounding with an attending physician, take place every day at teaching hospitals around the country with remarkably little consensus around best practices. At our institution, there is also no clear standardization of rounds from one team to the next. The rounding literature suggests that there is room for improvement in areas such as communication with patients and nurses, efficiency in workflow, and teaching at the bedside. Thus, we set out to identify best practices for attending rounds.

METHODS: The study took place between January and April 2013. We solicited the opinions of six care provider groups that were significant

stakeholders in the process of attending rounds: residents, attendings, medical students, case managers, pharmacists, and nurses. A qualitative approach to data collection was undertaken, including one-on-one interviews, group meetings, and e-mail surveys with open-ended questions. Data were transcribed and de-identified and content analysis was performed. This involved at least two reviewers independently coding stakeholder practice recommendations. Consensus for a practice was designated when a majority of one stakeholder group or two or more groups recommended the same practice.

RESULTS: In total, 60 care providers participated in an interview, group meeting, or responded via e-mail, including 23 attendings, 24 housestaff, seven medical students, two medicine team pharmacists, and four nurses. A list of the 15 consensus best practices for rounds is listed in Table 1. We organized these recommendations into four major categories: patient-centered care, interdisciplinary team, education, and efficiency/productivity.

CONCLUSIONS: This study provides concrete, actionable best practice recommendations for standardizing rounds at a teaching hospital. The successful implementation of these best practices requires deliberate training and systems changes, especially for significant interventions such as patient-centered rounds and real-time order writing.

Table 1: Summary of rounding best practice suggestions

Patient-centered care	1) Prioritize bedside rounds for most patients 2) Elicit the concerns and goals of patients and families in a shared decision-making model of patient care 3) Prioritize the patient rounding order based on the 3 D's (Decompensating, Dischargeable, complex Decision-making)
Interdisciplinary Team	4) Daily multidisciplinary rounds for discharge planning should include case managers and physical therapists. 5) Keep the rounding team, including housestaff and students, together as much as possible 6) Invite the bedside nurse to rounds, preferably by phone call or page prior to the team's arrival at the bedside 7) Communicate the care plan and patient needs with all members of the team
Education	8) Minimize interruptions of intern or medical student presentations 9) Push students to commit to a diagnostic and therapeutic plan 10) Provide short feedback immediately following oral presentations 11) Set clear expectations for each team member's role during attending rounds
Efficiency/ Productivity	12) Perform a deliberate huddle before rounds to plan the patient rounding order 13) Use mobile computers or devices to write orders in real-time rather than generating a checklist 14) Set strict time limits for rounds on each patient 15) Generate advanced notice of discharges so pharmacy students can do medication teaching and prior authorizations

SATISFACTION WITH AND AFFORDABILITY OF HEALTH INSURANCE FOLLOWING MASSACHUSETTS HEALTH CARE REFORM: VIEWS OF SAFETY NET PATIENTS Leah Zallman^{1,2}; Rachel Nardin^{1,3}; Assaad Sayah^{1,3}; Danny McCormick^{1,3}. ¹Cambridge Health Alliance, Cambridge, MA; ²Institute for Community Health, Cambridge, MA; ³Harvard Medical School, Boston, MA. (*Tracking ID #1935029*)

BACKGROUND: Like the Affordable Care Act (ACA), the 2006 Massachusetts (MA) health reform law (fully implanted by 2008) expanded Medicaid coverage and created a health insurance exchange offering publicly subsidized private health insurance plans called Commonwealth Care (CWC). Low income residents were eligible for one of three CWC plans, with different cost sharing requirements, based on income. Prior studies raise concerns about affordability—in particular the calibration of cost sharing with income—of insurance post-reform but neither the affordability of nor satisfaction with specific insurance types has been directly compared previously. .

METHODS: Between August and December 2013, we conducted face-to-face structured interviews with 681 patients presenting to three emergency departments at a large integrated safety net health care system in the greater Boston area. We confirmed insurance type using a statewide database that is updated daily. We included patients aged 18–64, who spoke English, Portuguese, Spanish or Haitian Creole. We excluded severely ill patients. The survey assessed patients' views of the affordability of care and satisfaction with their insurance in order to understand whether cost sharing was well calibrated to income. Medicaid and CWC 1 plans were available for people with incomes <133 and 150 % of the federal poverty level (FPL), respectively and required no premiums and modest copays for medications only. CWC 2 and 3 plans were available for people with incomes 150–300 % FPL and required monthly premiums and had significant co-pays for most services; these were combined for our analysis (CWC 2+3). We used chi-square tests to compare outcomes by insurance type.

RESULTS: Of the 681 participants (81 % response rate), 16 % were uninsured, 5 % had CWC 1, 9 % had CWC 2+3, 42 % had Medicaid and 28 % had

private insurance. Patients insured by CWC 2+3 (71 %) and private insurance (78 %) were less likely to agree that their insurance is affordable than those insured by Medicaid (95 %) and CWC 1 (97 %) ($p<0.001$). Patients insured by CWC 2+3 (79 %) were less likely to report overall satisfaction with their plan, as compared to those insured by Medicaid (95 %), privately (90 %) and CWC 1 (98 %) ($p=0.003$). Satisfaction with services covered was also lower among those insured by CWC 2+3 (79 %) and among the privately insured (85 %) as compared to those insured by Medicaid (91 %) and CWC 1 (95 %), though this was of borderline significance ($p=0.057$). Uninsured patients (40 %) and those insured by CWC 1 (22 %) and CWC 2+3 (19 %) were more likely to report having delayed any care due to cost than were those insured by Medicaid (14 %) and the privately insured (16 %) ($p<0.001$). Uninsured (46 %) and privately insured patients (34 %) were more likely to have unpaid medical bills as compared to those insured by CWC1 (24 %), Medicaid (23 %) and CWC 2+3 (24 %) ($p=0.0002$).

CONCLUSIONS: Affordability and satisfaction with insurance in post-reform MA differs significantly by insurance type. Those insured under public or subsidized plans with minimal cost-sharing plans reported substantially higher rates of satisfaction and affordability of care compared with subsidized private insurance with higher cost-sharing or unsubsidized private insurance. Careful calibration of cost-sharing to income is likely to be important in maximizing affordability and satisfaction with insurance products offered to low to middle income individuals through health insurance exchanges under the ACA.

SCHEDULE II NARCOTIC USE, ABUSE AND CORRELATION WITH SAFETY MEASURES IN AN ACADEMIC PRIMARY CARE SETTING PRIOR TO THE INITIATION OF FORMAL OPIATE SAFETY POLICIES: A RETROSPECTIVE CHART REVIEW Peter Bartlett, Henry Ford Hospital, Detroit, MI. (*Tracking ID #1941248*)

BACKGROUND: Since the late 1990's both prescriptions for opioids and opioid-related overdoses have increased three-fold. In 2009, 15,000 people died of opioid-related drug overdoses. The following year there were nearly half a million emergency room visits for non-medical use of opioids, and in 2011, 34 million Americans had used opioids at some time in their lives. The vast majority of opioids used in the United States are obtained through prescriptions, and nearly half of these prescriptions originate from primary care providers. Patients using excessive doses of opioids or obtaining prescriptions from multiple sources are much more likely to overdose. As well as initiating a uniform safety policy, our academic primary care clinic in urban Detroit studied who was receiving opioids, why they needed them, how frequently we were using identified "safety measures" and what association (if any) these safety measures had on opioid abuse.

METHODS: A retrospective chart review was performed by five investigators working in close collaboration. Inclusion criteria consisted of adult patients with non-malignant chronic pain prescribed a schedule II narcotic by a primary care physician in our clinic between the dates of March 1 and June 30, 2013. Exclusion criteria included history of malignancy, non-filling of the prescription, use of methadone for non-pain purposes and recent surgery. In addition to recording demographic information we recorded the presence or absence of perceived "safety measures" (use of an opioid risk screening tool, urine toxicology screen, pain contract, reassessment in clinic, referral to pain clinic). Aberrant behavior was considered early refills or multiple providers of opioids. Information was collected from our electronic medical record system and a state-wide electronic narcotic prescription tracking system. Data was analyzed by a professional statistician using Wilcoxon rank sum, Chi-square and Fisher exact testing methods.

RESULTS: 510 patients were assessed for eligibility; 200 excluded: 63 for having malignant pain, 82 for not being prescribed opioids at our internal medicine clinic or being on methadone. Of the 310 left, 85 patients were in the aberrant behavior group and 225 in the non-aberrant group. The most common pain complaint was back pain (32.6 %). In summary, a statistically significant difference between the aberrant and non-aberrant behavior patients have been detected for random urine toxicology status (28.2 % vs 16.9 %, $p<0.026$), pain clinic referral (35.3 % vs 24.4 %, $p<0.056$), re-evaluation of pain tapering (72.9 % vs 60.9 %, $p<0.048$), the safety measures score (2.1 vs. 1.5, $p<0.008$) and the ED/clinic visit variable (3.3 vs. 2.2, $p<0.001$).

CONCLUSIONS: Compared with other studies of chronic pain patients in the primary care setting, our patients had a similar distribution of age and pain complaints. We did have a significantly higher proportion of African American patients, consistent with our overall patient demographics. Our results suggest that the safety measures identified in this study are not sufficient to eliminate early prescription refills or "doctor shopping." Possible explanations of the positive

correlation between safety measures and aberrant behavior includes identification of at-risk patients by the primary care provider. An alternative explanation would be that poorly controlled pain could cause both "aberrant behavior" (e.g. early refills or seeking out a different provider) and additional "safety measures" (e.g. visit to the ED where a urine toxicology screen is standard prior to pain medication prescription). Further research is planned to follow these patients after implementation of uniform policies at the clinic.

SCREENING FOR HEPATITIS C VIRUS IN THE BABY BOOMER POPULATION: AN URBAN CLINICAL EXPERIENCE BEFORE AND AFTER CDC RECOMMENDATIONS Sarah Fishman, Robert E. Graham, Lenox Hill Hospital, New York, NY. (*Tracking ID #1940069*)

BACKGROUND: Hepatitis C Virus (HCV) chronically infects approximately 150 million people worldwide and 2 % of the US population. Prior to the screening of donated blood, HCV was transmitted through transfusion, and now is most commonly spread by exposure to contaminated needles shared by IV drug abusers. As many as 15 % of HCV patients may have acquired HCV infection via sexual contact. HCV infection is the leading indication for liver transplantation in the US, and in 2011 the average cost of healthcare expenses in a lifetime for an HCV infected individual was estimated at \$64,490. In May of 2013, the Centers for Disease Control (CDC) issued new recommendations regarding the screening of all patient born between 1945 and 1965, the so called "baby boomers" for HCV, noting that 75 % of chronically infected adults were born in those years. The CDC estimates that universal screening of adults born in this time period will prevent more than 120,000 deaths. We are investigating the impact of this recommendation on the rate of HCV screening in our urban (New York City), resident-physician staffed primary care clinic.

METHODS: We used our clinical scheduler program to identify patients born between 1945 and 1965 that were seen at least twice in our clinic between 8/7/2012 and 9/6/2013. We reasoned that it could take a few months for the news of the CDC recommendations to become common knowledge to practitioners in this clinic. Electronic laboratory records were further queried to identify those patients who were tested for HCV antibodies and/or HCV RNA. The paper charts of those patients were then manually curated to identify potential triggers for HCV testing. In the second phase of this investigation, we will identify a similar cohort of patients seen in the period from 9/7/2013 through 10/8/2014 and again examine the rate and triggers for HCV screening.

RESULTS: 849 patients were seen in our clinic within the designated time frame and met inclusion criteria for age. Of those, 26 (3.1 %) were tested for either HCV antibody or HCV RNA. Six (26.1 %) patients were found to be positive for both HCV antibody and viral RNA, and all six reported a history of active HCV infection. An additional five patients reported a history of HCV infection, hepatitis, or liver disease, but were found to be negative for HCV RNA. Two of these patients had antibody positivity, suggesting a cleared infection. All patients reporting a history of HCV infection were treatment naïve at the time of testing. Of the 15 (57.7 %) patients who were tested for HCV and did not report prior HCV infection or liver disease history, four were tested for HCV in the context of requesting testing for sexually transmitted diseases (STDs) and HIV. One patient was tested for HCV antibody due to unexplained liver enzyme abnormalities found on routine labs, and nine patients were tested without apparent reason to suggest possible HCV infection at the time of initial presentation to the clinic. No patient was found to be positive for HCV antibody or viral RNA who did not report a history of HCV infection.

CONCLUSIONS: Prior to the CDC recommendation for routine screening for HCV infection in the baby boomer population, HCV testing was infrequently performed, and was most often performed in the context of reported history of HCV infection and STD screening. HCV testing revealed a rate of 26.1 % prevalence among those tested, but did not uncover any new cases of HCV in this cohort. This investigation is ongoing to assess the impact of the CDC recommendations on the rate of HCV screening and prevalence of HCV infection. Interventions are planned to increase practitioner awareness of HCV screening recommendations and to identify patients who qualify for screening.

SCREENING FOR HEPATOCELLULAR CARCINOMA IN CHRONIC LIVER DISEASE: A SYSTEMATIC REVIEW Amiral Pasha²; Devan Kansagara^{1,2}; Joel Papak^{1,2}; Maya O'Neil¹; Michele Freeman¹; Rose Relevo¹; Ana Quinones²; Makalapua Motu'apuaka¹; Janice H. Jou^{1,2}. ¹Portland VA Medical Center, Portland, OR; ²Oregon Health and Science University, Portland, OR. (*Tracking ID #1939197*)

BACKGROUND: Hepatocellular carcinoma (HCC) incidence and mortality has increased over the past four decades abroad and in the United States, with localized tumors accounting for most of the increase. Guidelines recommend routine surveillance for hepatocellular carcinoma (HCC) in high-risk patients. However, recommendations for HCC screening remain controversial in part because of concerns over the quality and paucity of existing evidence, and because there have been concerns raised about overdiagnosis and patient harms in other cancer screening programs. We conducted a systematic review of the published literature to better understand the incremental benefits and harms of routine HCC screening compared to clinical diagnosis, and of treating HCC found as a result of screening.

METHODS: We searched Medline, PsycInfo, and Cochrane databases to March 2013; clinical trial registries; reference lists; and technical advisors. We included clinical trials and observational studies comparing screening to no screening, and clinical trials comparing different screening intervals. We also included clinical trials and observational studies comparing active to conservative treatment in patients with early-stage HCC. Mortality and adverse events were the main outcomes of interest. Because there were few comparative studies on treatments other than transarterial chemoembolization (TACE), we also examined noncomparative observational studies. The quality of studies and the overall strength of evidence were dual-reviewed using published criteria.

RESULTS: Of 11,321 citations, 264 were reviewed at the full-text level. Thirty-six studies contained primary data relevant to the efficacy of HCC screening or treatment of early-stage HCC and met our inclusion criteria. We also examined two systematic reviews of treatment modalities. Two trials and 16 observational studies provide very low strength evidence on the effects of screening on mortality because of methodologic flaws and issues of lead- and length-time bias. Moderate strength evidence from two trials shows no advantage of shorter screening intervals (3–4 months compared to 6–12 months). None of the included screening studies reported harms of screening. Low strength evidence from a meta-analysis of 8 studies found a risk of needle-track seeding from liver biopsy of 2.7 %. One recent systematic review of the diagnostic accuracy of imaging for HCC screening and diagnosis found very few studies reporting harms data: one study found contrast-enhanced CT was associated with adverse events in 13–15 % of patients, while another found mild-moderate adverse events in 25 % patients receiving gadoteric acid-enhanced MRI. We found no studies evaluating the psychologic harms of screening. No studies specifically enrolled patients with screen-detected HCC, so we examined studies of patients with early-stage HCC as a way of approximating screen-detected disease. Overall, there is little evidence with which to draw conclusions about the net benefits of actively treating early-stage HCC compared to conservative treatment. Observational studies show that patients selected for treatment with OLT, resection, or RFA had good long-term survival that was substantially higher than patients not selected for such therapy, but it is unclear whether such effects reflect a true effect of treatment or reflect confounding by indication. Serious harms occurred in 3–20 % of patients, depending on the intervention.

CONCLUSIONS: There is very low strength evidence from which to draw conclusions about the effects of HCC screening on mortality in high-risk patients with chronic liver disease. Screening tests can identify early stage HCC and patients who are selected for surgical treatment often have good long-term survival, but some treatments may be associated with substantial harms. There is very limited evidence to draw firm conclusions about the incremental benefits of using routine screening to identify HCC and treat HCC found as a result of routine screening. Trials examining the balance of benefits and harms of HCC screening in patients with chronic liver disease should be considered.

SEEING IS BELIEVING: VISION-RELATED QUALITY OF LIFE AMONG HOSPITALIZED PATIENTS Madeleine I. Shapiro¹; Vineet Arora²; Esther Schoenfeld³; Allison J. Louis¹; Alisha S. Ranadive⁴; Gavin W. Hougham⁴; Seenu M. Hariprasad⁵; David Meltzer⁴; Valerie G. Press⁴. ¹University of Chicago, Chicago, IL; ²University of Chicago, Chicago, IL; ³University of Chicago, Chicago, IL; ⁴University of Chicago, Chicago, IL; ⁵University of Chicago, Chicago, IL. (*Tracking ID #1934168*)

BACKGROUND: Impaired vision may be a risk factor for poor health outcomes during hospitalization, including falls and delirium. Additionally, hospitalized patients with poor vision may be unable to read critical documents such as consent forms. Vision also has large implications for quality of life, including the ability to interact with others and accomplish daily tasks both in and out of the hospital. Our previous work has shown that nearly one-third of hospitalized patients fail an inpatient vision screening. As such, the

hospital may represent a missed opportunity to address poor vision and its quality of life (QOL) implications. Therefore, our study set out to examine the prevalence and effect of poor vision on vision-related QOL among hospitalized patients.

METHODS: Hospitalized adult general medicine inpatients at the University of Chicago were enrolled in an ongoing study of resource-allocation and quality-of-care. Eligible patients (English speaking, cognitively intact) were given a vision screening (Snellen Eye Chart); those who had 20/50 or better visual acuity in at least one eye were classified as having sufficient vision. Health literacy was measured using the Rapid Estimate of Adult Literacy in Medicine Revised (REALM-R). Vision-related QOL was measured using the validated National Eye Institute 25-item Visual Functioning Questionnaire (VFQ, scale of 0–100) which covers vision health (near and far sight), social functioning (e.g., visiting people), and mental health (composite of being embarrassed, frustrated, having less control and worrying about vision problems), among other domains.

RESULTS: Of the 405 participants who completed the vision screening, the majority were female (57 %) and African American (77 %) with a mean age of 54 years. Among the participants, half (49 %) had ≤ a high school degree, about one-quarter ($n=92$, 23 %) had insufficient vision, and 35 % had poor health literacy. On the single item health screen, participants with insufficient vision were more likely to say they had less than or equal to good health than participants with sufficient vision (86/92, 93 % vs. 259/313, 83 % $p=0.01$). Those with insufficient vision were also more likely to report increased dependency on others ($p<0.001$), trouble with activities requiring near-vision ($p<0.001$), trouble with activities requiring far-vision ($p=0.001$), decreased social functioning ($p<0.001$) and decreased mental health ($p<0.001$). Participants under 65 had lower vision-related mental health than their older counterparts (81.9 vs. 86.6, $p=0.045$).

CONCLUSIONS: Given the high prevalence of poor vision and its relationship to diminished vision-related QOL among inpatients, the hospital may represent an important setting to identify patients with poor vision. Future work to test interventions to improve vision and related quality-of-life for inpatients are needed, especially for younger patients who may have the most to benefit.

SEEING THE LIGHT: EXAMINING VISION AMONG INPATIENTS WITH DIABETES (ENVISIONED STUDY) Madeleine I. Shapiro¹; Vineet Arora²; Allison J. Louis¹; Victoria I. Moreira³; Alisha S. Ranadive¹; Gavin W. Hougham⁴; Seenu M. Hariprasad⁵; David Meltzer⁴; Valerie G. Press⁴. ¹University of Chicago, Chicago, IL; ²University of Chicago, Chicago, IL; ³University of Georgia, Athens, GA; ⁴University of Chicago, Chicago, IL; ⁵University of Chicago, Chicago, IL. (*Tracking ID #1934153*)

BACKGROUND: Almost 3 million patients discharged from US hospitals annually have diabetes and more than one-quarter of older patients with diabetes are readmitted to the hospital within three months of discharge. Our prior work has shown that more than one-quarter of general medicine inpatients fail a vision screening test. However, to date, no data have specifically evaluated vision among inpatients with diabetes. Diabetic patients with poor vision may have difficulty performing self-care tasks related to their diabetes, such as injecting insulin. As such, the hospital setting may be a missed opportunity to screen for poor vision and improve access to diabetes related vision care; in-hospital interventions may improve patient self-management on discharge and decrease readmissions. In this pilot project, we aim to evaluate the prevalence of poor vision and characterize access to vision care for inpatients with diabetes.

METHODS: Hospitalized adult general medicine inpatients were enrolled in an ongoing study of resource-allocation and quality of care. Vision was tested using the Snellen eye chart; sufficient vision was defined as at least 20/50 in at least one eye. Health literacy was measured using a set of three verbal screening questions known as the brief health literacy screen (BHLS). Diagnosis of diabetes was determined based on self-report. Participants completed a survey about access to vision care. Descriptive statistics were used to determine means and proportions. Chi-squared tests were used for categorical comparisons.

RESULTS: Vision screenings were completed in 705 participants, the majority of whom were female (55 %) and African-American (77 %), with a mean age of 54. Among the participants, 34 % had diabetes (mean HbA1c 8.37, range 4.7–17.4), 30 % had poor health literacy, and 25 % had insufficient vision. Participants with diabetes were more likely than those without diabetes to have insufficient vision (74/239, 31 % vs. 101/466, 22 %; $p=0.007$). Participants with diabetes were also more likely to have poor health literacy (35 % vs. 27 %, $p=0.002$). Significantly more participants with diabetes reported that they “think that they need to see an eye doctor” (76/114, 67 % vs. 110/202, 54 %, $p=0.03$). While the majority of participants in both groups had ever seen an eye doctor (115/120, 94 % vs. 198/210, 96 %, $p=0.001$).

0.54), participants with diabetes tended to be less likely to have seen one within the last two years (76/100, 41 % vs. 110/156, 59 %, $p=0.3$). Further, more participants with diabetes were told that they have eye disease (49/115, 43 %, vs. 56/203, 64 %, $p=0.006$). As this is a pilot study, data collection is ongoing.

CONCLUSIONS: Early data from our pilot study demonstrate that the prevalence of poor vision is higher among inpatients with diabetes than those without diabetes. Additionally, the data suggest that access to vision care for patients with diabetes may be inadequate. The hospital setting may be an important opportunity to identify inpatients with diabetes and refer them for guideline-recommended care. Future work should address possible hospital-based interventions to reduce this disparity and improve vision-related transition care for patients with diabetes after discharge home.

SELF-REPORTED HEALTH STATUS PREDICTS OTHER-CAUSE MORTALITY IN MEN WITH LOCALIZED PROSTATE CANCER Richard Hoffman^{1,9}; Tatsuki Koyama²; Peter Albertsen³; Michael Goodman⁴; Ann S. Hamilton⁵; Janet Stanford⁶; Nan Stroup⁷; Arnold Potosky⁸; David Penson². ¹Albuquerque VA Medical Center, Albuquerque, NM; ²Vanderbilt University, Nashville, TN; ³University of Connecticut, Farmington, CT; ⁴Emory University, Atlanta, GA; ⁵University of Southern California, Los Angeles, CA; ⁶Fred Hutchinson Cancer Center, Seattle, WA; ⁷University of Utah, Salt Lake City, UT; ⁸Georgetown University, Washington, DC; ⁹University of New Mexico, Albuquerque, NM. (*Tracking ID #1937690*)

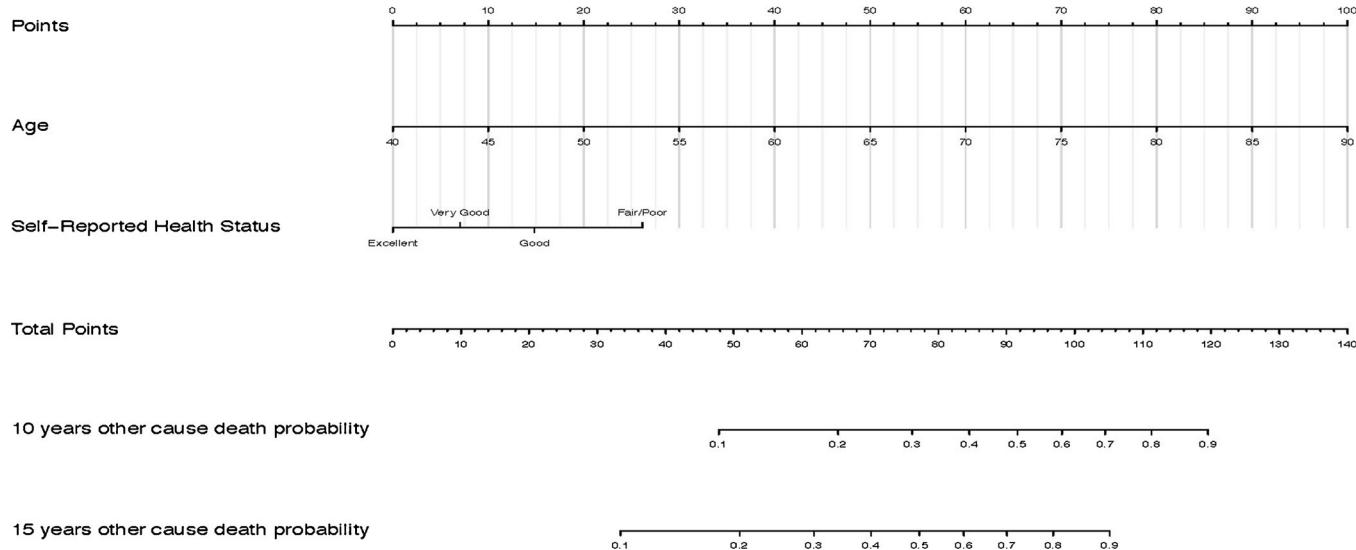

BACKGROUND: Prostate cancers detected by PSA testing are often indolent. Guidelines recommending against screening and treating men with limited life expectancy have had only limited impact on clinical practice. One problem is that physicians have difficulty accurately estimating life expectancy. We used data from the population-based Prostate Cancer Outcomes Study (PCOS) to develop a nomogram to predict 10- and 15-year other-cause mortality among a cohort of men with localized prostate cancer.

METHODS: The PCOS enrolled patients with prostate cancer diagnosed between October 1994 and October 1995. The study cohort for the current analysis was comprised of the men diagnosed with a localized cancer. Baseline measures included

demographics, socioeconomic status, comorbidity, tumor characteristics, treatment, quality of life, and a single-item on self-reported health status, with response options ranging from excellent to poor. We used Surveillance, Epidemiology, and End Results program and National Death Index data to determine date and cause of death through December 2010. We estimated other-cause mortality with a proportional hazards survival analysis accounting for competing risks. We then developed a nomogram for predicting risk for other-cause mortality based on age and self-reported health status at time of diagnosis.

RESULTS: The study cohort comprised 2,695 men, of whom 74 % underwent aggressive therapy (47 % surgery). At baseline, 18 % reported excellent health, 36 % very good health, 31 % good health, and 15 % fair/poor health. Healthier men were younger, more likely to be white, have private insurance, more years of education, and undergo surgery. By 15 years after diagnosis, 44 % of the cohort had died; 78 % of the deaths were from causes other than prostate cancer. Self-reported health status strongly predicted other-cause mortality; for men reporting excellent, very good, good, fair/poor health the cumulative incidences of other-cause mortality were 20 %, 29 %, 40 %, and 53 %, respectively, $P<0.001$. The competing-risks survival model with age and self-reported health status as the covariates and other-cause death as the outcome had a C-index of 0.72. The Figure shows the nomogram for predicting other-cause mortality based on age and self-reported health status. Increasing age and poorer self-reported health status were associated with increased risk for other-cause mortality. For example, a 69-year-old man reporting fair/poor health status had just over a 30 % chance of other-cause mortality after 10 years and a greater than 50 % chance of other-cause mortality after 15 years. Meanwhile, the corresponding risks for a 69-year-old man reporting excellent health were about 18 % and 28 %, respectively.

CONCLUSIONS: A one-item self-reported health status measure significantly predicted other-cause mortality 15 years after diagnosis with a localized prostate cancer. Men reporting fair/poor health had substantial risks for other-cause mortality suggesting limited benefit for undergoing aggressive treatment. Self-reported health status can be considered in supporting informed decision making about prostate cancer screening and treatment.

Nomogram for predicting other-cause death based on age and self-reported health status

SEX, GENDER, SOCIOECONOMIC STATUS AND ACCESS TO CARDIAC CATHETERIZATION IN THE CONTEXT OF UNIVERSAL HEALTHCARE COVERAGE Gabriel E. Fabreau^{2,1}; Alexander A. Leung^{5,3}; Danielle Southern³; John Z. Ayanian^{4,1}; William A. Ghali^{3,4}. ¹Harvard Medical School, Boston, MA; ²Brigham and Women's Hospital, Boston, MA; ³University of Calgary, Calgary, AB, Canada; ⁴University of Michigan, Ann Arbor, MI; ⁵University of Calgary, Calgary, AB, Canada. (*Tracking ID #1939475*)

BACKGROUND: Sex and gender disparities have been described in cardiac care and outcomes following acute coronary syndromes (ACS). Socioeconomic status (SES) may additionally affect medical care and health outcomes, partly through barriers in timely access to cardiac catheterization. In Canada, a universal healthcare system may reduce barriers related to sex/gender and SES. We sought to determine whether sex/gender and SES interact to modify the receipt of cardiac catheterization and mortality following an ACS in a universal healthcare system.

METHODS: Using a provincial multicenter cardiac registry, we assembled a cohort of 14,012 patients admitted with an ACS to any cardiology service in the southern health zones of Alberta, Canada between April 18, 2004 and December 31, 2011 by linking census, vital statistics and clinical registry data. SES was estimated using

residential neighbourhood median household income from the 2006 Canadian census. We compared the odds of receiving a cardiac catheterization within 1 and 30 days after admission, and the odds of death within 30 days and 1 year after admission according to income quintiles and stratified by sex. Using multivariable logistic regression we controlled for age, geography, cardiac risk factors and clinical comorbidities to estimate the adjusted odds ratios (ORs) of receiving cardiac catheterization and of death.

RESULTS: Unadjusted rates of cardiac catheterization were higher for men compared to women (41 % vs. 31 % at one day, and 68 % vs. 59 % at 30 days, $p<0.001$ for both time points), and in this context, men had lower mortality rates (2 % vs. 2.8 % at 30 days, and 5.2 % vs. 7.4 % at 1 year, $p<0.001$ for both time points). In models adjusting for SES, women were less likely to receive cardiac catheterization within 1 day (OR 0.79, 95 % confidence interval [CI], 0.71–0.87) and 30 days (OR 0.73, 95 % CI, 0.62–0.86) of admission with an ACS. When examined across quintiles of SES, adjusted models revealed differing relationships among variables for men vs. women: each incremental decrease in income quintile was associated with a 7 % lower odds of receiving cardiac catheterization for women ($p=0.005$) vs. a smaller 3 % decrement in odds for men ($p=0.03$). Additionally, among women, each decrease in income quintile was associated with a 13 % higher odds of 30-day mortality ($p=0.02$) vs. a 4 % higher odds of 30-day mortality for men ($p=0.39$). No SES differences were seen in the adjusted 1-year odds of death for either men or women, nor between them.

CONCLUSIONS: The relationships between socioeconomic status and use of cardiac catheterization and mortality after ACS are different for men vs. women, with women seemingly more vulnerable to the detrimental associations of low income. These findings were present despite a universal healthcare system that does not have any patient user fees. This suggests that factors other than insurance status and/or ability to pay are at play, and that elements of sex and/or gender are effect modifiers. Care protocols designed to improve access to care and improve outcomes in women, especially low SES women, are required.

SHARING TRAINEE NOTES WITH PATIENTS: ANTICIPATED EFFECTS OF OPENNOTES ON GRADUATE MEDICAL EDUCATION Bradley Crotty^{1,2}, Melissa Anselmo², Deserae Clarke³, Lydia A. Flier², Jamie Green⁴, Suzanne Leveille², Roanne Mejilla², Rebecca Stametz³, Jan Walker², Sigall K. Bell². ¹Beth Israel Deaconess Medical Center, Boston, MA; ²Beth Israel Deaconess Medical Center, Boston, MA; ³Geisinger Health System, Danville, PA; ⁴Geisinger Health System, Danville, PA. (Tracking ID #1937097)

BACKGROUND: OpenNotes is a national initiative inviting patients to read visit notes through a secure patient portal. Although HIPAA gives patients legal access to their medical records, the process can be prolonged and costly, limiting its use. Patients and PCPs report positive experiences with OpenNotes, but little is known about the potential impact of open notes on trainee education and practice.

METHODS: We conducted 7 focus groups with 24 medical and surgical residents and 12 faculty preceptors during 2013 at 2 hospitals prior to OpenNotes implementation. An expert facilitator led each session, discussing attitudes about OpenNotes, concerns, potential benefits, and educational implications. Sessions were recorded and transcribed. We analyzed transcripts using methods established by Crabtree and Miller.

RESULTS: Transcripts revealed 3 central themes: 1) Anticipated effects of transparency (including making clinician thought process “visible” to patients, uncertainty about how much to share, teaching trainees about note nuance, the “power of print” to motivate or offend patients, and “inversion of trust,” where doctors now need to trust their patients); 2) Ideology of a note (including questions about notes’ inherent educational value, purpose, and ideal audience), and 3) concerns about time pressures (including trainee fatigue, responding to patient calls/questions, and faculty overburden limiting proofing, teaching, and timely note turnaround). Participants voiced the following additional concerns: note errors compromising patient trust, note editing capabilities, documentation becoming more vague, ambiguity about documenting sensitive information, notes being hurtful to some patients and inaccessible to others—potentially leading to information access disparities. Potential benefits, included spearheading innovation, improved patient engagement and safety, increased preceptor feedback/supervision, more open discussions with patients, improved note quality (stemming of copy/paste and judgmental language), and possible patient feedback as an educational tool. Participants believed educational interventions should focus on medical students. Trainees emphasized patient education and expectation-setting. Both groups felt that if faculty were sharing notes, trainees should too.

CONCLUSIONS: Trainees and preceptors agree that trainees should be included in OpenNotes, despite concerns about potential effects on the patient-doctor relationship,

preceptor oversight requirements, and the sweeping issue of workload. Note transparency may expose existing imperfections in healthcare delivery and “force” confrontation of challenging issues like adequate supervision, time, and supports for trainees, preceptors, and patients—but also may offer innovative educational opportunities and patient care benefits.

SLEEP HABITS, QUALITY OF LIFE AND SATISFACTION WITH ACADEMIC SUCCESS IN SECOND YEAR MEDICAL STUDENTS

Kay Johnson^{1,2}, Nancy Simon¹; Mark Wicks¹; Doug Schaad¹; Karen P. Barr¹; Kim O'Connor¹.

¹University of Washington School of Medicine, Seattle, WA; ²VA Puget Sound Health Care System, Seattle, WA. (Tracking ID #1938934)

BACKGROUND: Pre-clinical medical students’ sleep is not yet determined by call schedules or patient care workload, but rigorous academic demands, high aspirations, and sometimes anxiety about their future may impact students’ ability to protect time for sleep and other vital activities. Sleep deprivation can negatively impact efficiency and performance, but may also be associated with depression, anxiety, and poor quality of life. Little has been published about medical students’ sleep habits, which may be a modifiable variable in student wellness. We surveyed second year medical students about their sleep habits to determine whether quantity of sleep is associated with perceived quality of life and academic success.

METHODS: Second year medical students at a large public university responded anonymously to a written questionnaire in the Spring quarters of 2011 and 2012 regarding several components of sleep, including their average amount of sleep on weeknights, weekends, and nights prior to a quiz or an exam, as well as their perception of their personal sleep needs. Other previously validated questions explored burn out, depression and perceived stress. Satisfaction with their quality of life and academic success was also assessed, as well as their perceived efficiency of study and retention of information.

RESULTS: Three hundred seven medical students completed the survey (response rate 68 %). Mean age was 26.4 years. When asked, “In general, how many hours of sleep does your body require for you to function optimally?” the mean response was 7.68 h; 90 % reported needing at least 7 h of sleep. Seventy-one percent said they get significantly less sleep than ideal during the academic year. On typical weeknights, the mean reported number of hours of sleep was 6.9 (range 4–10), with 6.4 on nights prior to a quiz (range 2–10) and 5.7 on nights prior to an exam (range 0–9). In the past academic year, 93 students (30 %) had “pulled an all-nighter” and twenty-five students (8.3 %) reported nodding off while driving. More sleep on weeknights was associated with a lower risk of screening positive for burnout ($p=0.04$) or depression ($p=0.01$), higher reported satisfaction with quality of life ($p=0.0001$), and higher satisfaction with academic success ($p=0.0043$). More weeknight sleep was not associated with perceived efficiency of study or retention of information.

CONCLUSIONS: Chronic sleep deprivation was common among the second year students participating in this study. Little sleep was frequently reported prior to exams, when high performance was most desired. Over 8 % of students have nodded off while driving during this academic year. Though a causal relationship could not be confirmed based on this study, higher levels of weeknight sleep were associated with less burnout and depression, and higher quality of life. Though students may assume they must sacrifice their sleep to achieve academic success, more sleep was actually associated with higher satisfaction with academic success. Research on effectiveness of educational and/or behavioral interventions to increase medical student sleep is needed, and evaluation of medical school curriculum reform efforts should take sleep variables into account.

SMARTPHONE-REPORTED STRESS AND DRUG EVENTS AND DAY-END PERCEIVED STRESS, HASSLES, AND MOOD IN METHADONE-MAINTAINED INDIVIDUALS

Karran A. Phillips; David H. Epstein; Michelle L. Jobes; Kenzie L. Preston. NIDA/NIH, Baltimore, MD. (Tracking ID #1939477)

BACKGROUND: The consistent finding that there is an overlap in the neural circuitry affected by stress and drug use and animal behavior studies showing that acute stressors (e.g., tail pinching, etc.) increase the likelihood of drug-seeking behavior support the causal role of stress in addiction and relapse. Human self-report and laboratory studies also suggest that stress is a clinically significant precipitant of relapse. We sought to determine relationships among drug use and stressful events (reported in real time) and day-end reports of perceived stress and hassles utilizing smartphones.

METHODS: Opioid-dependent methadone-maintained individuals in a 12-month natural-history study carried smartphones for up to 36 weeks to provide Ecological

Momentary Assessment (EMA) data. They initiated event-contingent entries whenever they used drugs or experienced a stressful event, and completed a day-end assessment every night, including 5 items from the Perceived Stress Scale (PSS), 32 hassle items from the Hassles and Uplifts (HS) Scale, and a brief mood assessment.

RESULTS: Participants ($n=102$; 76 men, 26 women) reported 1,016 stress events, of which 613 (60 %) had corresponding day-end assessments, and 1,171 drug-use events, of which 832 (71 %) had corresponding day-end assessments. Compared to days on which no stress events were reported, stress-report days had higher day-end PSS scores (mean \pm SD, none 6.2 ± 3.3 vs. stress 6.5 ± 3.7 , $p=0.04$) and higher day-end HS scores (mean \pm SD, none 2.2 ± 3.6 vs. stress 3.6 ± 4.5 , $p<0.005$). Compared to days on which no drug use was reported, drug-use days had higher day-end PSS scores (mean \pm SD, none 6.1 ± 3.4 vs. drug 7.3 ± 3.2 , $p<0.05$) and higher day-end HS scores (mean \pm SD, none 2.2 ± 3.6 vs. drug 2.9 ± 4.4 , $p<0.005$). On days on which a stress event was reported, individuals more often rated their mood at the end of the day as angry/annoyed/afraid ($p<0.005$) and sad ($p=0.006$) and less often as content ($p<0.005$). On days on which drug use was reported, individuals more often rated their mood at the end of the day as sad ($p=0.005$) and less often as happy ($p=0.003$).

CONCLUSIONS: Using smartphones and EMA to collect real-time in-the-field data, we found that both drug and stress events are associated with higher day-end perceived stress, perceived hassles, and negative mood among opioid-dependent individuals in methadone maintenance. In addition to focusing on reducing drug use, addiction treatment should include education on stress, hassles, and mood management.

STANDARDIZING THE DEFINITION OF REDUCED MOBILITY WHEN ASSESSING THE PATIENT'S RISK OF VENOUS THROMBOEMBOLISM

Alexander Weick; David Paje; Bronwyn Small; Muhammad Usman; Jainil Shah. Henry Ford Hospital, Detroit, MI. (Tracking ID #1916252)

BACKGROUND: Immobilization is known to be an important contributing factor to venous thromboembolism (VTE). However, the currently available risk assessment models for VTE in hospitalized medical patients use variable definitions of reduced mobility that are difficult to standardize and to apply prospectively. We sought to evaluate the physician's ability to determine at the time of admission whether a patient will have reduced mobility for at least 3 days.

METHODS: Physicians were asked to complete a standard data collection tool during their initial evaluation of patients admitted to the general medical units of an 805-bed teaching hospital. The tool captured baseline demographic data and clinical variables included in the Padua Risk Assessment Model (PRAM). To assess mobility status, physicians were asked whether they anticipate reduced mobility for at least 3 days that is limited to no more than bed rest with bathroom privileges. This was later compared to the patient's actual ability to ambulate independently on the 3rd hospital day as determined by the patient's nurse.

RESULTS: Of the 351 patients enrolled in the study, 123 (35 %) were expected to have reduced mobility by their admitting physician and 154 (44 %) were considered high-risk for VTE based on a PRAM score of ≥ 4 . Among those high-risk for VTE, 111 (72 %) were expected to have reduced mobility, while only 12 (6 %) of those who were low-risk were anticipated to be immobile ($p<0.0001$). The physician's prediction at the time of admission of the patient's reduced mobility during hospitalization had a sensitivity of 76 % (95 % Confidence Interval [CI], 66 % to 84 %) and a specificity of 81 % (95%CI, 75 % to 86 %). The positive and negative predictive values were 62 % (95%CI, 52 % to 71 %) and 89 % (95%CI, 84 % to 93 %), respectively.

CONCLUSIONS: The physician's anticipation of patient's reduced mobility is fairly reliable in predicting actual mobility during hospitalization. This may be used to standardize the operational definition of reduced mobility when assessing the patient's risk of VTE.

STATE FIREARM LEGISLATION AND NONFATAL FIREARM INJURIES

Joseph Simonetti^{1,2}; Ali Rowhani-Rahbar^{3,5}; Douglas Zatzick^{3,6}; Bessie Young^{7,2}; Frederick Rivara^{3,4}. ¹University of Washington, Seattle, WA; ²School of Public Health, University of Washington, Seattle, WA; ³University of Washington, Seattle, WA; ⁴University of Washington, Seattle, WA; ⁵School of Public Health, University of Washington, Seattle, WA; ⁶University of Washington, Seattle, WA; ⁷Northwest Center of Excellence, VA Puget Sound, Seattle, WA. (Tracking ID #1938977)

BACKGROUND: Stricter state firearm legislation has been shown to be associated with lower rates of fatal firearm injuries. However, less is known regarding nonfatal firearm injuries (NFI), which are more common than fatal injuries, and differ in

several ways, including age of the injured, intent, and type of firearm involved. The aim of this study was to determine whether stricter state firearm legislation is also associated with lower rates of NFI.

METHODS: We performed a cross-sectional, ecological analysis using available retrospective data from 17 states collected through the 2010 Healthcare Cost and Utilization Project (HCUP) State Inpatient Databases, which include information on more than 95 % of all discharges from community hospitals. We defined each case of hospitalized NFI as a patient discharged alive with an External Cause of Injury Code (E-code) for firearm injury (Assault [E965.0–4], intentional self-inflicted [E955.0–4], unintentional [E922.0–3, .8, .9], or undetermined [E985.0–4]). The primary predictor of interest was the Brady Score, a measure of state firearm legislative strength based on 2009 scorecards created by the Brady Campaign to Prevent Gun Violence. Scores are based on laws related to firearm trafficking, background checks, child safety, and restrictions on military-style assault weapons and firearms in public places. The Brady Score ranges from 0 to 28, with higher scores indicating more stringent laws, which we categorized into quartiles. The primary outcome was total hospitalized NFI. Secondary outcomes were assault-related, self-inflicted and unintentional hospitalized NFI. We calculated age-adjusted total hospitalized NFI rates for each participating state and used Poisson regression with clustered robust sandwich standard error estimates to determine if states in the highest quartile of legislative strength had fewer total, assault-related, self-inflicted and unintentional hospitalized NFI than states in the lowest quartile. Using data from the 2010 U.S. Census, we adjusted each model for the following state characteristics: age distribution, gender composition, racial/ethnic composition, population density, percentage with a college degree, percentage living below the federal poverty line, and unemployment rate.

RESULTS: The median Brady Score in 17 HCUP-participating states was 7 (interquartile range 4–16). Rates of total hospitalized NFI ranged from 1.7 (Hawaii) to 12.0 (Maryland) per 100,000 individuals. In unadjusted analyses, compared to states in the lowest quartile of legislative strength, those in the highest quartile of legislative strength had lower rates of self-inflicted (incident rate ratio [IRR] 0.33; 95 % confidence interval [CI] 0.27–0.41) and unintentional (IRR 0.53; 95 % CI 0.43–0.66) hospitalized NFI. In multivariable models, states in the highest quartile of legislative strength had lower rates of total (IRR 0.42; 95 % CI 0.34–0.50), assault-related (IRR 0.44; 95 % CI 0.35–0.57), self-inflicted (IRR 0.26; 95 % CI 0.22–0.31), and unintentional (IRR 0.27; 95 % CI 0.22–0.32) hospitalized NFI.

CONCLUSIONS: Findings of this cross-sectional, ecological study indicate that stricter state firearm legislation is associated with lower rates of all types of hospitalized nonfatal firearm injuries.

STATIN PRESCRIBING FOR PRIMARY PREVENTION: WHAT MIGHT THE 2013 ACC/AHA GUIDELINES ACHIEVE?

Harb Harb¹; Michael B. Rothberg¹; Brian Wells²; Bo Hu². ¹Cleveland Clinic, Cleveland, OH; ²Cleveland Clinic, Cleveland, OH. (Tracking ID #1937737)

BACKGROUND: The Adult Treatment Panel III guidelines for cholesterol testing and treatment in primary prevention were based on cardiovascular risk factors and LDL cholesterol targets. In contrast, the new American College of Cardiology/American Heart Association (ACC/AHA) 2013 guideline focuses exclusively on cardiovascular risk, with statins recommended for all patients with a 10-year risk of >7.5 % using a new population-based risk calculator. One concern is that the ACC/AHA guidelines may lead to initiation of statin therapy for more patients, including many who would have been considered to be lower risk by the earlier criteria. In contrast, the previous focus on LDL may have led to overprescribing for patients with high LDLs and low risk, or underprescribing for those with low LDLs but high risk. The objective of this study is to quantify the potential change in statin prescribing patterns using the ACC/AHA guidelines compared to current practice for patients without CHD equivalents.

METHODS: We conducted a retrospective cross sectional study of patients aged between 30 and 75 years old who received a first outpatient primary care visit at the Cleveland Clinic between January 1, 2005 and December 31, 2012. Patients with incomplete data, contraindications to lipid lowering medications (history of statin induced rhabdomyolysis, myositis or myopathy, transaminitis, statin allergy); lipid-lowering agent(s) prescribed at their first encounter (implying that they were already taking lipid lowering therapy); and patients with CHD or CHD equivalents (CVD, PVD, Diabetes) were excluded. For each patient we collected the following information from the time of their first lipid panel: age, sex, and race; as well as total, HDL and LDL cholesterol, smoking status, systolic blood pressure and whether they were treated with an antihypertensive medication. Patients were then stratified according to 10-year cardiovascular risk into 3 groups—low (<5 %), intermediate (5–

15 %) and high (15 %)—based on the Framingham equation. We then compared the number of patients in each stratum who actually received statins to the number in that same stratum that would be recommended to receive statins based on the ACC/AHA guidelines (i.e. those with a 10-year risk of >7.5 % based on the new risk calculator). We then calculated the number of cardiac events prevented over 10 years under current practice to those that could have been prevented by following the ACC/AHA guidelines using the formula: $E = N * R * RRR$ where E is the number of events prevented, N is the number of patients taking statins, R is the average Framingham risk of the patients taking statins, and RRR is the relative risk reduction related to statin use. We estimated the risk reduction to be 27 %, based on a Cochrane Review of statins for primary prevention.

RESULTS: Of 98,136 patients who had an initial visit (with LDL measured) during the study period, 85,079 (87 %) patients met inclusion criteria. Of these, 41,376 (49 %) were low risk, 30,135 (36 %) intermediate risk, and 12,768 (15 %) high risk based on their Framingham risk scores. Mean patient age was 48 years, 42 % were male, 79 % were white, 37 % were smokers and 27 % were taking medication for hypertension. The comparison of statin use appears in the Table. The total number of patients treated with statins under current practice was 13,896; 31 % of these were high risk and 22 % were low risk. Under the ACC/AHA guidelines, 17,294 patients would qualify for treatment; 70 % would be high risk and 1.4 % low risk. Assuming that statins reduce the risk of a major cardiac event by 27 %, then the total number of events currently being prevented is 510 per 10 years, with NNT=27. Under ACC/AHA criteria the number of events prevented would be 1034, with NNT=17.

CONCLUSIONS: Compared to current practice, following the ACC/AHA guidelines would increase the total number of patients on statins. However, it would decrease use among low and intermediate risk patients, while markedly increasing use among high risk patients, thereby decreasing the total number of major cardiac events as well as number needed to treat.

Statin prescriptions by CHD risk

Framingham 10-year CHD risk	All Patients	Statins Under Current Practice	Statins Under ACC/AHA Guidelines	p-value
	N (%)	N (%)*	N (%)*	
Low (<5 %)	41,376 (49 %)	3000 (7 %)	234 (0.6 %)	<0.001
Medium (5–15 %)	30,135 (36 %)	6441 (21 %)	4973 (17 %)	<0.001
High (>15 %)	12,768 (15 %)	4317 (34 %)	12087 (95 %)	<0.001

STIGMA AND THE UTILIZATION OF SERVICES FOR MENTAL HEALTH ISSUES IN MEDICAL STUDENTS Gwen Thompson¹; Rosanne McBride²; Colin P. West¹; Gwen W. Halaas². ¹Mayo Clinic, Rochester, MN; ²University of North Dakota, Grand Forks, ND. (Tracking ID #1938859)

BACKGROUND: There is a high prevalence of depression and burnout among medical students. While medical students are taught that mental health issues are disease processes with treatment options, there is still an underutilization of services in this population. This study explores the utilization of services for mental health issues and the stigma perceived regarding this health issue among medical students at the University of North Dakota School of Medicine and Health Sciences (UNDSMHS).

METHODS: A cross-sectional study was used to survey 253 students at UNDSMHS with a survey response rate of 63.6 %. The Maslach Burnout Inventory Human Services Survey was used to evaluate burnout. Depression was assessed using the Patient Health Questionnaire. Additional items pertaining to demographic information, the diagnosis and treatment of depression, the cause of depression and 27 stigma statements regarding depression were also included in the survey. These additional items were adopted with permission from the authors of a previous study.

RESULTS: Of the total respondents, 17.0 % (26 of 153, 95 % CI [11.0 %, 23.0 %]) were experiencing moderate to severe depression and 48.5 % (64 of 132, 95 % CI [40.0 %, 57.0 %]) were experiencing burnout. Of the moderately to severely depressed, 80.8 % (21 of 26, 95 % CI [65.7 %, 95.9 %]) were not diagnosed and 84.6 % (22 of 26, 95 % CI [70.7 %, 98.5 %]) were not being treated for depression. When asked why depression develops, 22.6 % (35 of 155, 95 % CI [16.0, 29.2]) responded that it was due to an inability to cope. No students replied that it was solely attributed to a neurotransmitter abnormality. Among the 27 stigma statements, those who had moderate to severe depression differed in their responses compared to those

who had no or mild depression on 12 statements. For example, students with moderate to severe depression were more likely to agree that seeking help for depression would make them feel less intelligent as a medical student ($p<0.01$, OR 7.9, 95 % CI [2.8, 22.1]), telling a counselor would be risky ($p=0.04$, OR 3.5, 95 % CI [1.2, 10.3]) and depression is a sign of personal weakness ($p=0.03$, OR 5.9, 95 % CI [1.3, 25.8]).

CONCLUSIONS: Students at the UNDSMHS have rates of depression and burnout similar to those of medical students across the nation. The majority of students at the UNDSMHS were not diagnosed and underutilized treatment services. Despite medical training that mental health is a disease process, more than one fourth of medical students stated that depression develops due to an inability to cope. Medical students also still endorse statements of stigma regarding mental health issues. This is particularly true for students who are categorized as moderately to severely depressed. It is unknown if the stigma perceived by those suffering from mental health issues is amplified by their disease process or if those who are suffering from mental health issues have experienced the negative effects of this stigma first-hand and are therefore able to better comment on it. Investigating the etiology of this perceived or real stigma and addressing the source is an important next step in successfully helping medical students help themselves.

STRONG MEDICAL SCHOOL INDUSTRY INTERACTION POLICIES HAVE NO PROTECTIVE EFFECT ON STUDENTS' BEHAVIOR AS RESIDENTS: RESULTS OF A NATIONAL SURVEY James Yeh¹; Kirsten Austad¹; Jessica M. Franklin¹; Susan Chimonas²; Eric Campbell²; Jerry Avorn¹; Aaron Kesselheim¹. ¹Brigham and Women's Hospital and Harvard Medical School, Boston, MA; ²Columbia University College of Physicians and Surgeons, New York, NY; ³Massachusetts General Hospital and Harvard Medical School, Boston, MA. (Tracking ID #1923322)

BACKGROUND: Medical students at schools with strong industry interaction policies are less likely to receive gifts and meet with sales representatives, and are more likely to have increased perception of adequacy of separation between faculties of their medical school and the industry when compared to students from schools with weak policies. However, it is unknown whether these behaviors and attitudes persist after graduation to residency training. We sought to determine whether there was an association between third-year residents' openness to meeting with and accepting gifts from pharmaceutical sales representatives and the strength of the industry interaction policies in place at the medical school they had attended. We also considered whether certain demographic or professional characteristics were associated with their behavior.

METHODS: We administered a mailed survey to 1714 third-year residents randomly identified from U.S.-based medical schools (15 graduates from each school). Survey asked about interactions with and acceptance of gifts from pharmaceutical sales representatives, as well as attendance of industry-sponsored educational events, that had occurred in the past 6 months of their residency training. We used hierarchical logistic regression models to determine the association between these outcomes and the strength of their medical schools' industry interaction policies measured by the Institute on Medicine as a Profession 3 years prior to the administration of the survey. In the final model, we adjusted for medical school class size, decision to enter primary care, plan to conduct translational research, and residents' concern about their medical school loan debt level.

RESULTS: Among 739 respondents (43.1 %), residents who graduated from medical schools with the strongest industry interaction policies had no statistically significant differences in the main outcomes when compared to graduates of medical schools with the weakest policies: there was no difference in the odds of receiving gifts (unadjusted odds ratio [OR] 0.77; 95 % Confidence Interval [CI] 0.31–1.96; $p=0.59$), accepting meals paid for by the industry (unadjusted OR 0.81; 95 % CI 0.28–2.29; $p=0.69$), interacting with sales representatives (unadjusted OR 1.11; 95 % CI 0.44–2.80; $p=0.82$), or attending educational events sponsored by the industry (OR 1.81; 95 % CI 0.69–4.76; $p=0.23$). These statistically non-significant results did not change substantially in the fully-adjusted model.

CONCLUSIONS: Residents' behavior toward industry sales representatives was not associated with the strength of the industry interaction policies at the medical school they previously attended. These results suggest that residents adapt to the marketing interaction norms at their training hospitals. Any "protective effect" from strong industry interaction policies in insulating students from pharmaceutical marketing during medical school did not carry over to the next stage of their clinical training. Industry interaction policies may be less common, or less stringently enforced, in the hospitals and outpatient clinics in which medical trainees work during their residency.

Increased attention should be paid to managing industry interactions throughout medical training.

STUDENT GOALS FOR SUB-INTERNSHIPS; A STUDY OF TWO INSTITUTIONS Beth Liston¹; Deepthi Rao². ¹The Ohio State University, Columbus, OH; ²University of New Mexico, Albuquerque, NM. (*Tracking ID #1938454*)

BACKGROUND: As residency programs adapt curricula to the ACGME milestones, the fourth year of medical school will play an important role in preparing students to meet the minimum competencies for entering interns. Organizations are trying to define learning outcomes for these students. However, there is little written on what knowledge and skills students themselves hope to gain in their sub-internship rotations. Clearly this is important data as incongruous institutional and student goals will lead to failed programming efforts.

METHODS: Students doing a sub-internship between April 2010 and April 2012 at University of New Mexico and between July 2012 and July 2013 at Ohio State University wrote their own rotation objectives. The students at the University of New Mexico completed an internal medicine sub-internship whereas at the Ohio State University students completed either an internal medicine, family medicine, pediatrics, general surgery, neurology, urologic surgery or neurosurgery rotation with the majority choosing internal medicine, family medicine or pediatrics. At both institutions, no didactic examination contributed to the student's grade. The objectives were grouped into themes and coded by the authors. The numbers of students giving each goal were tabulated.

RESULTS: There were 40 students at the University of New Mexico. Each student was allowed to write unlimited goals. There were 175 students at Ohio State University. Each student was asked to write three goals. The goals most often written at the University of New Mexico were increasing skills in patient management (29), efficiency (18), note writing (17) and dictation (15) and least often written were knowledge of pain management (1), wanting experience with being on call (1), using the lab (1) and gaining skill in listening to heart murmurs (1). The goals most often written at the Ohio State University were increasing skills with patient management (71), increasing medical knowledge of pulmonary problems (67), increasing medical knowledge of renal problems (44), and procedures and least often written were increasing skills with cardiac exam/heart murmurs and assessing residency program

CONCLUSIONS: This two-institution study suggests that (1) learning clinical care (ACGME competency Patient Care) during the sub-internship was perceived as an important goal by students at both medical schools, but the importance of acquiring of medical knowledge (ACGME competency Medical Knowledge) varied considerably among medical students at the two schools; and (2) improving physical examination skills and learning procedures (ACGME competency Patient Care) was not an objective for the vast majority of students at both schools. Students individual objectives for their learning may inform institutional curricula. National efforts to standardize sub-internship experiences should take this into account.

STUDENTS LEAD THE WAY FOR LIFESTYLE MEDICINE INTEGRATION INTO MEDICAL EDUCATION Camille Clarke^{1,5}; Ingrid Edshteyn^{2,3}; Colin Zhu⁴.

¹Cambridge Health Alliance, Cambridge, MA; ²Columbia University, New York, NY; ³Griffin Hospital, Derby, CT; ⁴Robert Wood Johnson Medical School, Freehold, NJ; ⁵Harvard Medical School, Boston, MA. (*Tracking ID #1939725*)

BACKGROUND: Lifestyle practices profoundly influence short-term and long-term health along with overall quality of life. The majority of chronic diseases are preventable and significantly influenced by poor lifestyle choices. Practice guidelines for chronic disease prevention and management recommend that treatment begin with evidence-based lifestyle medicine interventions as the primary modality. Physicians, however, cite inadequate confidence and lack of knowledge and skill as the major barriers to counseling patients about lifestyle interventions. A change is imminent in addressing this gap and health professional trainees have begun to proactively implement lifestyle medicine initiatives. The past 3 years has seen a rise in student-led interest groups for lifestyle medicine, however the motivation, goals, facilitators, and impediments for these developments remain largely unknown. The purpose of this study was to evaluate the perceptions of lifestyle medicine student interest group leaders on the importance and inclusion of lifestyle medicine in their medical school curricula, their motivation for starting the group, the major lifestyle medicine topics of interest as well as barriers in starting and maintain the groups on their campuses.

METHODS: A 10 question online survey was distributed to eight student leaders of six medical school lifestyle interest groups. Their participation was voluntary, stating

the intent of developing standardized lifestyle medicine resources for student groups. Results were reported anonymously and grouped for the final analysis.

RESULTS: Seven medical student leaders responded to the survey. While all stated that it is either important (57 %) or very important (43 %) to include training in Lifestyle Medicine within medical education, the majority (85 %) stated that their medical school equipped students to provide only some (43 %) or very little (29 %) lifestyle recommendations for patients. All cited personal interest as motivation for starting their interest groups along with lack of content in medical curriculum (57 %) and lack of content in other interest groups (71 %). All respondents stated that lack of educational or supportive resources as the primary barrier in starting the medical school group, and it remained the greatest barrier (83 %) in maintaining the interest group. Nutrition, physical activity, stress management, and clinical lifestyle medicine practice models were ranked as the four most important lifestyle medicine topics in their interest groups.

CONCLUSIONS: National guidelines assert the importance of lifestyle counseling by physicians in addressing the preventable chronic disease epidemic. Our results show a growing number of medical student leaders have taken the initiative with a proactive approach in establishing lifestyle medicine interest groups to address the current gap in medical school curricula. Personal interest, lack of content in curricula and lack of content in other interest groups are cited as the main reasons for beginning these groups. The major initial and continuing impediment is a lack of educational or supportive resources. It will be our nation's imperative to strengthen and enable these lifestyle medicine student interest groups and medical school curricula for treating the cause of both preventable and chronic disease.

SUBCLINICAL THYROID DYSFUNCTION AND FRACTURE RISK: AN INDIVIDUAL PARTICIPANT DATA ANALYSIS OF PROSPECTIVE COHORTS Manuel R. Blum¹; Douglas Bauer²; Bruno R. da Costa³; Christina D. Wirth¹; Anne R. (*Tracking ID #1930001*)

BACKGROUND: Subclinical thyroid dysfunction is common, particularly with increasing age. Controversy persists as to whether screening and treatment of subclinical thyroid dysfunction are warranted, as current evidence about the risks and effects of treatment is limited. Data from several prospective cohorts on the association between subclinical thyroid dysfunction and fracture events are conflicting. These conflicting results might be attributed to differences in age, gender, thyrotropin (TSH) levels, power and varying cut-offs of the studies.

METHODS: After a systematic literature review, we performed an individual participant pooled data analysis from all available prospective cohorts of adults with measurement of baseline thyroid function and fracture outcomes. We examined hip, non-spine, clinical spine and any fractures. We defined euthyroidism as TSH 0.45–4.49 mIU/L, subclinical hyperthyroidism as TSH<0.45 mIU/L with normal free thyroxine (FT4) levels and subclinical hypothyroidism as TSH≥4.50–19.99 mIU/L with normal FT4 levels.

RESULTS: Among 13 prospective cohort studies with 69,795 participants during 757,219 person-years of follow-up, 4044 (5.8 %) participants had subclinical hypothyroidism and 2091 (3.0 %) had subclinical hyperthyroidism. During follow-up, 2901 participants (among 12 studies) had a hip fracture, 2018

(8 studies) had non-spine fractures, 320 (7 studies) had spine-fractures, and 2600 (9 studies) had any fracture. In age and gender-adjusted analyses, the overall hazard ratio (HR) for individuals with subclinical hyperthyroidism of any cause compared to euthyroidism was 1.39 (95 % confidence interval, 1.10–1.76) for hip fracture, 1.16 (0.95–1.41) for non-spine fracture, 1.54 (0.96–2.47) for spine fracture, and 1.28 (1.07–1.54) for any fracture. The risk of fracture increased with lower TSH levels for every fracture outcome (all p for trend ≤ 0.02). Compared to euthyroid participants, HRs for those with TSH < 0.10 mIU/L were 1.67 (1.21–2.30) for hip fracture, 1.72 (1.11–2.68) for non-spine fracture, 3.57 (1.88–6.78) for spine fracture, and 2.01 (1.49–2.71) for any fracture. Risks were similar after further adjustment for known osteoporotic fracture risk factors such as BMI and smoking. The attributable risk for subclinical hyperthyroidism was 28 % for hip fracture and 22 % for any fracture. Endogenous subclinical hyperthyroidism (no use of thyroid hormone) was associated with increased fracture risk for all fracture outcomes, with HR of 1.56 (1.20–2.02) for hip, 1.27 (1.02–1.59) for non-spine, 1.74 (1.01–2.99) for spine and 1.42 (1.16–

1.74) for any fracture. Subclinical hypothyroidism was not associated with fracture risk. HRs for participants on thyroid medication ($N=2737$) vs. untreated euthyroid participants were 1.36 (1.15–1.61) for hip, 1.31 (1.08–1.59) non-spine, 1.34 (0.87–2.07) for spine and 1.24 (1.04–1.47) for any fracture.

CONCLUSIONS: Pooled individual data from 13 prospective cohorts confirm that subclinical hyperthyroidism is associated with an increased risk of hip and other fractures, particularly in those with a TSH concentration < 0.10 mIU/L. Subclinical hypothyroidism is not associated with fracture risk, but treatment with thyroxine is associated with increased fracture risk. Our study cannot address whether treatment of subclinical hyperthyroidism reduces fracture risk, but our results indicate that trials of subclinical hyperthyroidism treatment are needed to identify optimal management strategies in these individuals.

Age and gender-adjusted risks associated with subclinical hyperthyroidism (vs. euthyroidism)

	No. outcomes / participants	TSH <0.45 mIU/L vs. euthyroidism: HR (95 % CI)	TSH 0.10–0.44 vs. euthyroidism: HR (95 % CI)	TSH <0.10 vs. euthyroidism: HR (95 % CI)	P for trend *
Hip fracture	2'616 / 58'106	1.39 (1.10–1.76)	1.37 (0.99–1.90)	1.67 (1.21–2.30)	0.002
Non-spine fracture	1'846 / 22'651	1.16 (0.95–1.41)	1.03 (0.81–1.30)	1.72 (1.11–2.68)	0.02
Clinical spine fracture	292 / 21'312	1.54 (0.96–2.47)	1.19 (0.65–2.20)	3.57 (1.88–6.78)	< 0.001
Any fracture	2'378 / 27'041	1.28 (1.07–1.54)	1.11 (0.89–1.39)	2.01 (1.49–2.71)	< 0.001

CI, confidence interval; HR, hazard ratio; TSH, thyroideal-stimulating hormone * P for trend across TSH categories (euthyroidism 0.45–4.49 mIU/L, TSH 0.10–0.44 mIU/L, and TSH < 0.10 mIU/L)

SUBCLINICAL THYROID DYSFUNCTION AND THE RISK OF FRACTURES: A META-ANALYSIS Christina D. Wirth¹; Manuel R. Blum¹; Bruno R. da Costa^{2,3}; Tinh-Hai Collet⁴; Marco Medici⁵; Robin P. Peeters⁵; Drahomir Aujesky¹; Douglas Bauer⁶; Nicolas Rodondi¹; ¹Inselspital, Bern University Hospital, Bern, Switzerland; ²University of Bern, Bern, Switzerland; ³University of Bern, Bern, Switzerland; ⁴University Hospital of Lausanne, Lausanne, Switzerland; ⁵Erasmus Medical Center, Rotterdam, Netherlands; ⁶University of California, San Francisco, CA. (Tracking ID #1920246)

BACKGROUND: The prevalence of subclinical thyroid dysfunction is high and increases with age. Data on the association between subclinical thyroid dysfunction and fractures are conflicting. We aimed to assess the risk of hip and non-spine fractures associated with subclinical thyroid dysfunction among prospective cohort studies.

METHODS: Medline and Embase (1946 to May 2013) and reference lists of retrieved articles were searched without language restriction. Two reviewers screened articles and selected prospective cohort studies that measured thyroid function and followed participants to assess hip and non-spine fracture outcomes. Data were extracted using a standardized abstraction form. Adjusted estimates for hip and non-spine fractures from each study were pooled using a random effects model. For heterogeneity between studies, we assessed the Q statistic with a conservative p-value of 0.1 and the I² statistic ($I^2 > 50\%$ indicating at least moderate statistical heterogeneity).

RESULTS: Among 1052 screened articles, we identified eight studies that met eligibility criteria. All eight were population-based cohorts and included a total of 53,181 participants with 2278 hip fractures and 6085 non-spine fractures. In random-effects models, the pooled adjusted hazard ratios (HRs) of participants with subclinical hyperthyroidism vs. euthyroidism were 1.27 (95 % confidence interval, 0.99–1.62) for hip fractures and 1.16 (1.00–1.34) for non-spine fractures. Pooled estimates for a TSH cutoff ≤ 0.1 mIU/L increased the HR for hip fractures to 2.04 (1.50–2.79) and the HR for non-spine fractures to 1.99 (1.54–2.57). After excluding one study that only included participants taking thyroid hormone and did not measure free thyroxine level, the HRs for subclinical hyperthyroidism were 1.43 (1.03–1.97) for hip fractures and 1.20 (0.98–1.49) for non-spine fractures. For participants with subclinical hypothyroidism, pooled HRs were 1.22 (0.93–1.60) for hip fractures and 1.21 (0.85–1.71) for non-spine fractures, both with heterogeneity across studies ($p < 0.10$ and $I^2 > 50\%$). In two studies of subclinical hypothyroidism with only thyroxine users, the HRs were 1.69 (1.24–2.29) and 1.77 (1.36–2.30), respectively.

CONCLUSIONS: Our systematic review indicates that subclinical hyperthyroidism may be associated with an increased risk of hip and non-spine fractures, particularly

in those with a TSH concentration of 0.1 mIU/L or less. Oversubstitution may explain the observed increased fracture risk for subclinical hypothyroidism among thyroxine users. Given the high prevalence of both osteoporosis and subclinical thyroid dysfunction in our aging populations, our findings have public health implications.

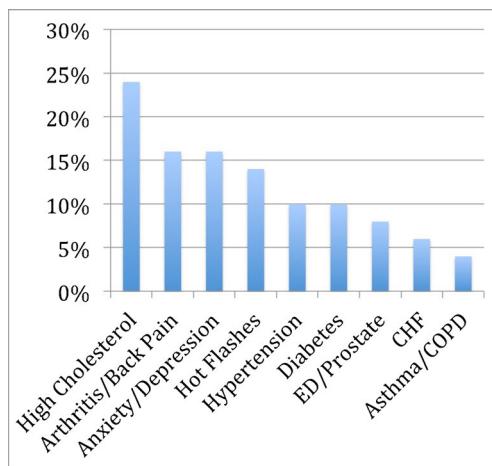

SUBSTITUTION OF VITAMINS AND SUPPLEMENTS FOR PRESCRIPTION MEDICINE AMONG VETERANS Jennifer N. Goldstein¹; Doris Arevalo²; Judith A. Long¹; Jun Mao¹. ¹University of Pennsylvania, Philadelphia, PA; ²University of Illinois, Urbana-Champaign, IL. (Tracking ID #1936713)

BACKGROUND: Previous research suggests that patients may substitute vitamins and supplements for their prescriptions when medications are unaffordable. Since recent evidence has questioned the efficacy and safety of nutritional supplements, it is important to understand whether patients are using ineffective and potentially harmful products because conventional care is unaffordable. This study sought to determine the prevalence of substitution of vitamins and supplements for prescription medications among veterans and whether substitution is associated with prescription rationing due to cost.

METHODS: We conducted a cross sectional survey study among veterans at primary care clinics at the Philadelphia VA Medical Center. Substitution was measured by asking “in the past 3 months have you taken a dietary supplement to treat or prevent a health problem or condition instead of taking a prescription drug?” Prescription rationing was measured by asking “in the past 3 months have you ever taken less of any medication than prescribed by your doctor because of cost?” Both questions were obtained from the National Health Interview Survey from the CDC. We performed bivariate and multivariate analyses with substitution as the dependent variable to determine the relationship between substitution and prescription rationing. Other variables included in the multivariate model were age, sex, race, educational level, and copay-exempt status at the VA.

RESULTS: Among the 275 veterans who completed surveys, 206 (75 %) used vitamins, supplements and herbs, and of those, 46 (22 %) substituted. Hyperlipidemia, back pain/arthritis and anxiety/depression were the most common conditions for which substitution was performed (See Figure). In the multivariate logistic regression, veterans who rationed their prescriptions due to cost were more likely to substitute (AOR 3.57, 95 % CI 1.38–9.25).

CONCLUSIONS: Veterans who ration prescriptions due to cost are more likely to substitute vitamins and supplements for prescription medications. This raises concerns that in spite of the low cost or free prescriptions provided by the VA, veterans may still experience financial strain and make treatment choices that could negatively impact their health. Since most Americans do not receive highly subsidized health care, our findings likely underestimate the magnitude of substitution due to cost within the general population.

Conditions for which Veterans use Vitamins and Supplements Instead of Prescription Medication

SUCCESS OF A FACULTY DEVELOPMENT PROGRAM FOR REMEDIATING CLINICAL TEACHERS Thomas J. Beckman; Staci Lee; Mark Lee; Darcy Reed; Andrew J. Halvorsen; Elie Berbari; Furman S. McDonald. Mayo Clinic, Rochester, MN. (*Tracking ID #1935708*)

BACKGROUND: The remediation of medical learners has been widely studied, but there has been limited research on the remediation of clinical teachers. The objective of this study was to determine whether a faculty development program could improve the evaluations of underperforming clinical teachers in an internal medicine residency program.

METHODS: 123 teachers completed faculty development at the Mayo Clinic from 2009 to 2012. The faculty enhancement and education development program (FEED) consists of six one-hour sessions that are taught by experienced Mayo Clinic faculty. These sessions address the following competencies: asking questions, diagnosing learners, giving feedback, utilizing teaching frameworks, recognizing learning styles, and providing clinical supervision. Resident-of-faculty Mayo teaching effectiveness (MTE) scores have previously demonstrated content, internal structure and criterion validity. Teachers were grouped into the top 80 % or the bottom 20 %, according to baseline MTE scores. Scores from all the MTE items were combined to form an overall score ranging from 1 to 5. Mixed linear models were used to compare these groups regarding changes in MTE scores after completion of FEED. Results were adjusted for teacher age, gender, medical specialty, academic rank, and teaching awards.

RESULTS: Of the 123 faculty members in this study, most (N,%) were males (82, 67) in non-procedural specialties (88, 72), and they averaged 9 years on faculty and 45.4 years of age. A small proportion of faculty members had received major teaching awards (12, 10), and only a minority held advanced ranks of associate professor or professor (29, 24). For all faculty combined, the adjusted MTE scores (mean; standard error) improved from baseline (3.80; 0.04) to completion of the FEED intervention (3.93; 0.04; $p < 0.0001$). However, the bottom 20 % of teachers had a significantly greater improvement in scores than the top 80 % (score-change difference = 0.166; $p < 0.0001$). In multivariate models, there were significant associations (β ; p-value) between changes in scores after exposure to FEED and the following variables: bottom 20 % versus top 80 % of teachers (0.166; $p < 0.0001$), age (-0.007 ; $p < 0.0001$), procedural versus non-procedural specialty (-0.119 ; $p < 0.0001$), academic rank (β range: -0.166 – 0.263 ; $p < 0.0001$), and receiving a teaching award (0.074; $p < 0.0001$). There were no significant associations for years on faculty (tenure) or gender.

CONCLUSIONS: We describe a faculty development initiative that was effective at remediating underperforming clinical teachers in internal medicine. These findings have implications for improving the quality of graduate medical education programs.

SUFFERING BURNOUT: THE INTERNAL MEDICINE RESIDENT'S QUALITATIVE EXPERIENCE Kate Jennings^{1,2}; Chad Stickrath^{1,2}; Ravi K. Gopal^{1,2}.

¹Veterans Affairs Administration, Denver, CO; ²University of Colorado Denver School of Medicine, Aurora, CO. (*Tracking ID #1939433*)

BACKGROUND: Burnout is a response to work related stress characterized by depersonalization, emotional exhaustion and a sense of loss of personal efficacy. Burnout affects approximately 67 % of internal medicine residents. Prior studies have detailed the impact of burnout on the professional, personal and social lives of physicians. The literature has not provided examples of how residents experience burnout in their daily lives. We sought to describe how burnout influences the experience of Internal Medicine (IM) residents and how it impacts their view of themselves, their relationships and their patient care.

METHODS: As a part of an end-of-year survey, IM residents were asked to free list the most common behaviors that occur when they or one of their fellow residents are burned out. Residents were allowed to list up to three behaviors and were not limited by space or characters. Through a qualitative content analysis of responses, we derived a codebook using both deductive and inductive code development. Deductive codes were derived using two systematic reviews of burnout in medical residents. To capture the nuances within the codes, we used inductive code development to expand the original deductive codes. The final definitions of the deductive and inductive codes and subcodes were tested using portions of the dataset. A second researcher (KJ) read through the responses and further revised the codebook. The final codebook was applied to the entire qualitative dataset and major themes were derived.

RESULTS: Among the 166 residents that were invited to participate, 108 (65.1 %) subjects completed the survey. Of the respondents, 86 % listed at least one behavior and 49 % listed 3 behaviors. Two hundred sixty-five individual responses were collected. "Attitudes and behaviors" was the most common theme, with the subcode of "negative state of being" as the most frequent (13.2 %) with responses such as "negative, bitter, angry, bad attitude and irritable". The "interactions with colleagues" theme with the subcodes of "negative behavior" (12.8 %) was frequent, and responses detailed "arguing with other residents, talking negatively about other residents, becoming 'mean' towards peers, and aggressive pimping". A theme of "patient care" (9.8 %) emerged with residents stating that burnout causes "neglectful care, negative attitudes towards patients and insufficient time spent with patients." The idea of poor patient care was followed by themes of "cutting corners" (9.4 %) with behaviors including "shoddy work, missing details, not prepared for rounds, mistakes in orders, and poor medical decision making." Additional themes of the resident responses detailed the impact of burnout on "teaching and learning", "self-evaluation" and "career satisfaction".

CONCLUSIONS: Burnout is very common among IM residents and influences their experiences during residency. Burnout negatively impacts a resident's sense of well-being, their relationships with other residents and the perception of the care they provide. Further, residents correlate burnout with cutting corners in patient care, demonstrating specific ways that patient safety and outcomes may be adversely affected by the internal medicine resident's experience of burnout.

SUPPORT FOR A SINGLE PAYER NATIONAL HEALTH INSURANCE PROGRAM SIX YEARS AFTER MASSACHUSETTS HEALTH CARE REFORM: VIEWS OF SAFETY NET PATIENTS Sonali Saluja^{1,2}; Leah Zallman^{4,1}; Rachel Nardin²; David Bor^{2,1}; David Himmelstein³; Steffie Woolhandler³; Danny McCormick^{2,1}. ¹Harvard Medical School, Boston, MA; ²Cambridge Health Alliance, Cambridge, MA; ³City University of New York School of Public Health, New York, NY; ⁴Institute of Community Health - Cambridge Health Alliance, Cambridge, MA. (*Tracking ID #1936229*)

BACKGROUND: Prior to health care reform, polls showed broad support for a universal, government-run national health insurance program (NHI), sometimes called a "single payer" system. In 2006, the state of Massachusetts implemented health insurance reform that became the model for the Affordable Care Act (ACA). It included a Medicaid expansion, an insurance exchange offering subsidized and unsubsidized private health insurance and individual and employer mandates for coverage. The MA reform was fully implemented by 2008. Little is known, however, about which financing system is preferred by Massachusetts residents after 6 years of experience with the reform.

METHODS: Between August 5, 2013 and December 19, 2013, we conducted face-to-face structured interviews with a sample of 867 patients presenting to three emergency departments at safety net health providers in the greater Boston, Massachusetts area. We included patients aged 18–64 who had only one insurance type and spoke any of the four major local languages—English, Portuguese, Spanish or Haitian Creole. We excluded the most severely ill patients—those with an Emergency Severity Index of 1 (1 to 5 point scale). The overall survey response rate was 82.4 %. We asked respondents whether they

supported the current insurance system in Massachusetts or an alternative NHI system run by the government and paid for by taxes. In addition to collecting demographic information, we asked respondents about their knowledge, satisfaction and concerns about affordability with their current health plan. We calculated the overall proportion of respondents supporting NHI, and evaluated predictors of such support using chi square tests.

RESULTS: Overall, 73.0 % (548/751) of survey participants preferred NHI to the reformed MA health system ($p<0.0001$). Preference for NHI did not vary significantly by age, race, education or income group, although women (76.1 % [328/431]) were more likely to support it than men (68.6 % [218/318]; $p=0.02$). Uninsured respondents were the most supportive of single payer NHI (84.0 %), followed by the privately insured (71.7 %) and the publically insured (70.7 %; group p-value=0.02). Among insured respondents, 87.8 % of those who were dissatisfied overall with their plan supported NHI compared to 70.1 % of those who were somewhat or very satisfied ($p=0.009$). Similarly, 82.5 % of respondents who were dissatisfied with their plan's affordability supported NHI, compared with 69.8 % of those who were satisfied ($p=0.03$). Patients who experienced a delay in any medical care due to cost were more likely to favor NHI (81.0 % versus 70.8 %; $p=0.01$).

CONCLUSIONS: A majority of Massachusetts safety-net hospital patients, a group encompassing key populations targeted by the reform, favor NHI over the existing system. Current national health care financing debates among politicians and health policy experts focus almost exclusively on the ACA. Our findings from Massachusetts suggest there is a potential disconnect between the preferences of individuals who have experienced health reform and the narrow debate focused on the ACA - implying a broader discourse that includes a single payer health system is warranted.

SUPPORTING COORDINATION OF MEDICAID HOME- AND COMMUNITY-BASED SERVICES: A DEFINITIONAL FRAMEWORK FOR INDIVIDUAL ASSESSMENTS FOR SENIORS AND PERSONS WITH DISABLING CONDITIONS USING NON-INSTITUTIONAL LONG-TERM CARE Lhasa Ray¹; Kathleen H. Wilber⁴; Robert Newcomer⁵; Debra Saliba^{2,3}. ¹University of California, Los Angeles, Los Angeles, CA; ²University of California, Los Angeles, Los Angeles, CA; ³Greater Los Angeles Veterans Affairs, Los Angeles, CA; ⁴University of Southern California, Los Angeles, CA; ⁵University of California, San Francisco, San Francisco, CA. (Tracking ID #1938056)

BACKGROUND: For low-income seniors and people with disabling conditions, Medicaid-funded home and community-based services (HCBS) ideally function in tandem with medical services to support independent living, enhance quality of life and reduce institutionalization. Too often, however, HCBS are provided through a disjointed array of programs that require multiple, redundant eligibility determination and service allocation processes. This lack of coordination is burdensome for recipients and inefficient for payers and service providers. For this reason, a number of states across the U.S. have initiated efforts to implement eligibility and care plan assessment processes that are integrated across Medicaid and state-funded HCBS programs. Despite increased recognition of the importance of creating standardized assessment systems for HCBS, no formal definitional framework for the components of assessment has been proposed. This project aimed to support the state of California's efforts to develop uniform assessment processes for its Medi-Cal HCBS programs by developing a definitional framework based on literature review and input from experts in the field.

METHODS: To develop a definitional framework that codifies the essential components of standardized assessment for Medicaid HCBS, the project team reviewed the peer-reviewed and grey literature. We also examined Medicaid waiver and state-plan documents for 5 states with developed standardized assessment systems identified by California program leads as potential learning models for California. From this initial work we constructed a preliminary framework that we further refined using a group process with 8 departmental leaders within California's Department of Health Care Services, Department of Social Services and Department of Aging who are familiar with existing Medicaid and state-funded HCBS systems in the state. Next, we used the framework to gather information about the components of evaluation and enrollment currently in use through key informant interviews with departmental leaders in the 5 comparator states (Michigan, New York, Pennsylvania, Texas, and Washington). Based on these interviews and feedback, we refined the framework further so that it provided clear and consistent nomenclature to describe practices in use by states.

RESULTS: Review of the peer and grey literature failed to identify an existing recognized framework. The subsequent framework development process resulted in

the identification of a series of relatively sequential stages of comprehensive assessment for program eligibility, service needs, and implementation of the plan of care. The final framework we developed is provided in the table.

CONCLUSIONS: This framework provides stages and definitions that can assist state leaders, policymakers, and others involved in designing, refining, or evaluating standardized assessment systems for Medicaid HCBS. This common framework can also improve communication among stakeholder groups and facilitate program or state comparisons by defining a nomenclature that can be applied across settings. Standardized assessment of an individual's program eligibility, need for services, and care plan adequacy is a fundamental tool for bringing coherence and efficiency to an often fragmented system for long term services and supports. Standardized assessment is compelling for several reasons. Coordinated assessment systems can facilitate consistent and reliable identification of an individual's met and unmet need for HCBS. At the program and provider level, uniformity could enhance information exchange across providers and programs, improving efficiency and promoting partnership between multidisciplinary teams. At the state level, a common set of assessment stages across departments and programs offers the potential to better understand the populations requesting services, to ensure resources are equitably distributed, and to improve planning across programs. Finally, standardized systems could contribute to better monitoring of quality and health outcomes. Standardizing HCBS delivery systems requires that fundamental definitions for system components are formalized. This framework provides the basis for designing and evaluating service delivery systems that maximize efficiency, communication, and coordination for Medicaid and state-funded HCBS.

< Components of Comprehensive Assessment/b>

Stage	Definition
Preliminary screen	Initial contact with applicant seeking to gain entry into an eligibility process or waiting list. Identifies who will go on to a more in-depth assessment.
Eligibility Determination	Determination that eligibility criteria for a specific program(s) are met. A needs assessment is typically accomplished as part of this stage in assessment. Results may also determine prioritization of care or position on program waiting lists.
» Functional Eligibility	For HCBS 1915(c) waiver programs, establishes that nursing home level of care criteria are met. Sometimes referred to as the 'level of care' determination.
» Financial Eligibility	Establishes that financial criteria are met. Identification of specific service needs.
Needs Determination	Development of a plan of service delivery that takes into account an individual's needs and goals of care, existing sources of care and support, and resources available through a range of formal programs and informal supports.
Care Planning	Establishing a budget or allocating service hours. May be generated by algorithms that rely upon information gathered during needs assessment or through the development of the care plan, or may be accomplished through a separate process.
Service Authorization	Establishing a budget or allocating service hours. May be generated by algorithms that rely upon information gathered during needs assessment or through the development of the care plan, or may be accomplished through a separate process.
Service Coordination, Case Management	Determination that services prescribed by the care plan match identified needs and services delivered, and that service delivery is timely.
Quality Monitoring	Includes reviews of completed assessments or aggregated data, as well as practices that ensure that data collection is consistent across assessors.
Reassessment	Repeated assessments accomplish one or more functions: (1) To verify continued eligibility (functional and/or financial), (2) To verify effectiveness of the care plan, and (3) To assess changing needs. Reassessments are typically conducted quarterly to annually or when there is a change in status.

SURGICAL AND MEDICAL HOSPITALIZATIONS: CAN THE SAME STRATEGIES BE USED TO DETECT THEIR PHYSIOLOGICAL DETERIORATION? Santiago Romero Brufau; Matthew G. Johnson; James M. Naessens; Bruce W. Morlan; Joel A. Hickman; Jeanne M. Huddleston. Mayo Clinic Rochester, Rochester, MN. (Tracking ID #1940758)

BACKGROUND: It is estimated that about 150,000 cardiorespiratory arrests (CRA) occur in US hospitals every year, with a survival to discharge less than 20 %. But

patients usually show signs and symptoms of deterioration hours or days before. Rapid Response Systems (RRS) were designed to improve the detection and intervention upon a deteriorating patient, and their acceptance and use has increased in recent years. They rely on accurate detection of acute physiological deterioration (APD). Published Early Warning Scores (EWS) have been proposed to help in the detection of APDs and have been evaluated in heterogeneous populations, but the same score is calculated for all patients irrespective of their frailty or whether they are surgical or medical. Predictive capacity of EWS may be different in medical vs surgical, or in frail vs non-frail patients.

METHODS: We created a time-stamped database including all discharges from January 2010 to December 2011 from two tertiary hospitals in Minnesota totaling approximately 1,500 general care (non-ICU) beds. Patients were categorized as surgical or medical based on whether they had been to the operating room during their hospitalization, and as frail or non-frail based on their Braden score. Outcomes were unscheduled transfers to the intensive care unit (ICU), activation of the RRS, and calls for cardiorespiratory resuscitation (code). Alerts that would have been issued using the published early warning scores were considered accurate if they predicted an outcome in the following 12 h. Predictive capacity of the most widely used Early Warning Scores (NEWS, ViEWS, MEWS, GMEWS, SEWS, Worthing and Kirkland) was calculated this way and compared between different groups of patients according to their Braden score and whether they were considered medical or surgical.

RESULTS: Our final dataset included more than 6,000,000 data points from 34,898 unique patients. There were 57 % surgical hospitalizations, and a total of 3,328 patients had a Braden score of 12 or less. There were 3,517 outcome events: 1,865 RRS activations, 203 codes and 1,449 unscheduled transfers to the ICU. All evaluated scores performed better (higher positive predictive value and sensitivity) on medical than on surgical patients. All scores had a positive predictive value below 25 %. Grouping the patients by Braden score had a heterogeneous effect on the predictive performance of the evaluated EWS.

CONCLUSIONS: Evaluated EWS show a higher predictive performance in medical than in surgical patients. Having different scores for medical and for surgical patients may allow for the improvement of their predictive performance. This suggests that different strategies should be used for the detection of acute physiological deterioration in surgical and medical patients.

SURROGATE MARKERS, COMPOSITE END-POINTS, DISEASE-SPECIFIC MORTALITY, OR ALL-CAUSE MORTALITY? A SURVEY TO UNDERSTAND THE RELATIVE VALUE CLINICIANS PLACE ON DIFFERENT OUTCOMES Tanner Caverly¹; Allan V. Prochazka²; Rodney A. Hayward¹; Daniel Matlock². ¹University of Michigan Medical School, Ann Arbor, MI; ²University of Colorado, Aurora, CO. (Tracking ID #1939177)

BACKGROUND: When weighing the importance of a risk reduction found in a clinical trial, clinicians and patients need to consider the clinical significance of what

was reduced. Improvements in surrogate and composite outcomes, for example, do not necessarily imply meaningful improvement in patient-oriented outcomes. Improvement in all-cause mortality is ideal, since it reflects the overall effect of therapies on mortality, but most trials are not large enough to assess this outcome. We conducted a survey that varied the type of benefit observed in hypothetical drug trials to evaluate the extent to which clinician perceptions changed based on the outcome evaluated. We hypothesized that perceptions would be relatively insensitive to the type of outcome reported in the hypothetical trials.

METHODS: Our survey consisted of 4 scenarios that were identical except for differences in the type of outcome: surrogate, composite, disease-specific mortality, or all-cause mortality (Table 1). Each participant received all 4 scenarios which were separated by unrelated questions in order to minimize direct comparisons. They were asked to rate the extent to which each scenario provided proof that the new drug might help people. Answers were on a 1–10 risk perception scale (ranging from 1 = no proof to 10 = good proof). Surveys were distributed during educational conferences to 3rd and 4th year medical students at a single academic institution, to internal medicine residents at two institutions, and to faculty in the division of general internal medicine at one institution. In addition, a national group of clinician-researchers with evidence based medicine expertise took an online version of the survey. We analyzed the distribution of responses for the 4 scenarios in two ways: 1) using analysis of variance to identify differences in the mean response between scenarios and 2) using simple descriptive statistics to evaluate how participants rated each question relative to their responses on the other 3 questions. We also used analysis of variance to examine how differences between mean responses on the all-cause mortality question and the disease-specific mortality question varied by level of training.

RESULTS: We received 546 completed surveys for analysis (response rate: 87 % for medical students [273/313]; 80 % for internal medicine residents [148/185]; 67 % for general medicine faculty [118/175]; and 41 % for the group of experts [7/17]). On average, participants rated the composite outcome as more valuable than the other types of outcomes (Table 1). Overall, 51 % rated improvement in a surrogate marker as equal to or more valuable than an improvement in all-cause mortality, and 79 % rated improvement in a composite outcome containing a surrogate marker as equal to or more valuable than improvement in all-cause mortality. Eighty percent rated improvement in stroke-related mortality as equal to or more valuable than an improvement in all-cause mortality. Mean differences in responses on the all-cause mortality question and the disease-specific mortality question varied by level of training (medical students rated improvement in stroke mortality an average of 1.5 points higher than improvement in all-cause mortality; residents 1.2 points higher; general medicine faculty 0.6 points higher; and experts 1.7 points lower).

CONCLUSIONS: Many clinicians in our sample over-value improvement in surrogate and composite outcomes and under-value improvement in all-cause mortality. This raises concerns that clinical decisions may not reflect the actual value of the intervention, especially if clinicians are exposed to information that emphasizes clinically less important outcomes.

Table 1. Mean response on a 1–10 scale when 546 medical trainees and physicians asked to "Rate the extent to which this provides proof that the new drug *might* help people." (1 = "no proof" and 10 = "good proof")¹

Category	Question	N	Mean ² (s.d.)
Surrogate outcome	<i>A large randomized trial shows that a new drug lowers serum levels of a risk factor known to be associated with an increased risk of death from stroke.</i>	545	4.5 (2.2)
Composite outcome (containing surrogate outcome and patient-oriented outcomes)	<i>In a large randomized trial, people in the new drug group experienced decreased rates of the combined primary end-point (non-fatal stroke, death, or elevated levels of a risk factor into the high risk category for stroke).</i>	545	6.6 (2.1)
Disease-specific mortality	<i>In a large randomized controlled trial, fewer people died from stroke in the new drug group than in the placebo group.</i>	546	6.4 (2.1)
All-cause mortality	<i>In a large randomized trial, fewer people died for any reason in the new drug group than in the placebo group.</i>	542	5.2 (2.3)

¹Participants were told that all of the results were statistically significant from large randomized trials with excellent validity and generalizability.

²Differences between group means are statistically significant at $P < 0.001$ on ANOVA.

SUSTAINABLE PATIENT-CENTERED MEDICAL HOME TRANSFORMATION IN SAFETY-NET CLINICS: LESSONS LEARNED FROM THREE CASE STUDIES Reshma Gupta¹; Edward Wagner²; Katie Coleman². ¹University of Seattle, Washington, Seattle, WA; ²McColl Center of Health Care Innovation, Group Health, Seattle, WA. (*Tracking ID #1933680*)

BACKGROUND: Although only 6 years have passed since the Patient-centered Medical Home (PCMH) was first proposed to reinvigorate primary care, thousands of practices have engaged in transformation activities. However, practice transformation has proven to be difficult and requires wholesale changes to the practice. The Commonwealth Fund sponsored a 5 year demonstration project, the Safety Net Medical Home Initiative (SNMHI), to help clinics become PCMHs. Despite the high level of support made available to each practice, practices varied widely in their transformation success. More intensive study of three successful SNMHI practices confirmed lessons learned in the larger project about: what motivates practices to demolish old ways of organizing and delivering care; what changes enable practices to see a better future and sustain the effort; and how do successful practices go about making changes?

METHODS: The goal of the SNMHI was to develop and test a replicable model for supporting PCMH transformation among 65 safety net practices in five states. Participating practices in each state were supported by a Regional Coordinating Center (RCC) that employed medical home facilitators (MHFs) who worked closely with individual clinics. Transformation was guided by an explicit PCMH model that consisted of eight high level areas for change process (Wagner). Measurement of the transformation process involved multiple instruments including the Patient-centered Medical Home Assessment (PCMH-A), a 33 item self-assessment (Daniels). To study the transformation process more intensively, we selected three practices of different sizes, geographic locations, and organizational structures among those that had made major progress in becoming PCMHs as measured by change in PCMH-A scores. The sites selected included clinic A (an urban FQHC in Oregon), clinic B (a small single-site rural clinic in Colorado), and clinic C (multi-site urban and rural FQHC in Idaho). Data collected included bi-annual PCMH-A and Key Activity Checklists, MHF bi-annual evaluation, PCC narrative reports about each practice, and clinical data from each site. To gain a deeper understanding of the transformation process, we identified individuals at each practice who played key roles in practice transformation. We then conducted semi-structured one hour long qualitative interviews either in person or by phone during February and March, 2013 with these practice leaders. We addressed domains including motivation to change, initial approach to change, role of leadership, key beneficial approaches to change, key barriers to change, and reflection on change process. Data analysis involved coding transcriptions of interviews and identifying themes within and across cases.

RESULTS: The mean overall PCMH-A score across the 65 sites rose from 7 to 9 (out of 12) over 3 years. The scores for clinics A, B, and C rose from 7.0 to 9.0, 5.3 to 10.0, and 6.9 to 9.3, respectively. Prior to the SNMHI, Clinic A had a long history of practice transformation initiatives, but progress had stalled. Clinics B and C had not previously been engaged in practice transformation. Following involvement in the SNMHI all three clinics generated the will or motivation to change, found attractive ideas to guide change, and developed a strategy and infrastructure that facilitated the execution of system changes. Medical and administrative leaders made transformation an organizational priority and visibly drove change. Intrinsic motivators such as concerns about quality of care or community reputation had greater impact on these clinics than extrinsic motivators such as external payments and meeting recognition standards. Ideas for change came primarily from exposure to faculty and other sites in SNMHI learning sessions, or visiting other clinics farther along in the transformation process. We found that practices were able to execute sustained transformation once their leaders were committed to the transformation process, and a trusted performance measurement system and an explicit approach to studying and testing changes in work processes were in place. The sequence with which clinics made the changes to become a PCMH was important. Clinics that hadn't formally linked patients with specific providers or established well-functioning practice teams found it difficult to provide optimal coordinated care.

CONCLUSIONS: Practice transformation is challenging; however, we hope that it will help to describe how high-performing clinics developed and used will, ideas, and execution to transform themselves. The will for becoming a PCMH must be felt among staff at all levels, and the ideas motivating change were expedited by involvement with transformation initiatives and exposure to more advanced practices. The execution of successful practice transformation built upon a foundation of engaged leaders, available performance measures, and an explicit strategy for testing and implementing changes.

SYMPTOM BURDEN IN PATIENTS HOSPITALIZED FOR DECOMPENSATED HEART FAILURE Rabeea Khan¹; Shelli L. Feder³; Nathan Goldstein²; Sarwat Chaudhry¹. ¹Yale School of Medicine, New Haven, CT; ²Mount Sinai School of Medicine, New York City, NY; ³Yale University School of Nursing, New Haven, CT. (*Tracking ID #1930389*)

BACKGROUND: Heart failure is one of the most common reasons for hospitalization among older adults, and is the leading cause of readmissions within 30 days after hospital discharge. Consequently, there is great interest in developing strategies to reduce hospital utilization in this large and growing patient population. Aside from the classic heart failure symptoms of dyspnea and fatigue, other symptoms that have been reported in patients with heart failure include pain, decreased appetite, anxiety, as well as difficulty sleeping. These symptoms may be amenable to treatment, and as such, patients hospitalized with heart failure may benefit from intensive symptom management in the form of palliative care. However, there is limited data in the heart failure population about symptom burden both during hospitalization and shortly after hospital discharge, as well as patients' perceptions of palliative care.

METHODS: Patients hospitalized with a primary diagnosis of decompensated heart failure at Yale-New Haven Hospital were enrolled in this prospective cohort study. Exclusion criteria included non-English speaking, severe cognitive impairment, and ongoing hemodialysis. Patients were interviewed about their symptom burden using the Edmonton Symptom Assessment System (ESAS) and the Patient Health Questionnaire (PHQ-8) during their hospital admission ("baseline interview"). A follow-up telephone interview was conducted seven to days after hospital discharge, assessing symptom burden using the same standardized instruments. Patients were also questioned about their existing knowledge of palliative care, and then—after a brief, standardized explanation of the goals of palliative care—patients were queried about their interest in receiving palliative care services.

RESULTS: Thirty-five patients were enrolled in the study from September–December 2013. Their mean age was 71.3 years (SD 13.5 years) 54 % were female, and 71.4 % had NYHA class III or IV heart failure. The most frequent symptoms reported during the baseline interview were tiredness (82.9 %), drowsiness (82.9 %), shortness of breath (62.9 %), anxiety (57.1 %) and pain (45.7 %). The most frequent symptoms reported in the follow-up interview were tiredness (93.9 %), drowsiness (81.8 %) shortness of breath (81.8 %), anxiety (57.6 %) and pain (57.6 %). While only 14.3 % of patients had heard of the term "palliative care," after a brief, standardized explanation of what palliative services are designed to do, 45.7 % were interested in receiving palliative care services while in the hospital.

CONCLUSIONS: Patients hospitalized for heart failure experience a high burden of symptoms, including not just dyspnea and fatigue but also anxiety and pain. These symptoms are common during hospitalization, but the majority of patients experience troublesome symptoms shortly after discharge as well. Given that symptoms frequently drive health care utilization, integration of palliative care into routine heart failure management is a promising strategy to reduce hospital utilization.

TACKLING HEALTH EQUITY: LEADERSHIP'S PERCEPTIONS OF HEALTH CARE PERSONNEL AND ORGANIZATIONS Brooke A. Cunningham¹; Pamela J. Johnson^{1,2}; Todd Rockwood³. ¹Medica Research Institute, Minnetonka, MN; ²University of Minnesota School of Public Health, Minneapolis, MN; ³University of Minnesota School of Public Health, Minneapolis, MN. (*Tracking ID #1938695*)

BACKGROUND: Demographic shifts, health care reform, value-based reimbursement, and increased interest in population health are encouraging health systems to act on equity. Although Minnesota ranks high nationally for overall health care quality, it also has high levels of health disparities. This study uses survey methods to examine the perceptions of health care leaders regarding the engagement of health care personnel and delivery systems with health equity.

METHODS: Six health systems in Minnesota invited their senior leaders to a health equity forum in the summer of 2013. As part of the program evaluation, invitations to complete a web-based survey were sent to those who registered for the conference. Respondents were asked to rate senior leaders, mid-level managers, and front-line providers' and staff's awareness of health inequities, engagement in addressing health disparities, and sense of "safety" discussing racial and ethnic disparities. They were also asked to rate the factors that contribute to health disparities and the effectiveness of their organizations in addressing those factors. Paired t-tests were used to compare

respondents' perceptions of the engagement of employee groups and health care organizations respectively with health disparities.

RESULTS: The response rate was 41 % ($n=37$). Most respondents were white (89 %), female (59 %), had graduate training (86 %), and attended the health equity forum (95 %). Respondents perceived senior leaders to be significantly more informed about health equity, more engaged with addressing disparities, and to feel safer discussing racial/ethnic disparities than mid-level managers and front-line providers and staff respectively. Regarding health system priorities, addressing disparities ranked last, behind 1) reducing medical error; 2) reducing costs/improving customer service; and 3) improving performance measures. Respondents perceived social determinants to be a significantly larger contributor to disparities than any other factor (i.e., individual behavior, health care systems, health insurance, and access barriers). However, compared to these other factors, they reported health systems to be least effective at addressing social determinants of health.

CONCLUSIONS: Leaders from six health systems in Minnesota perceived organizational engagement with health equity to vary by occupational tier. They perceived social determinants of health to be the greatest contributor to disparities but reported that health systems were least effective at addressing them. This data suggests that health system leaders may need to further promote health equity goals with their mid-level managers and front-line providers and staff. This will require identifying and reducing barriers to the uptake of health equity as an organizational priority. If health care leaders highlight how health equity intersects with other organizational goals, promoting health equity may be seen as facilitating the achievement of, rather than competing with, other priorities.

TARGETED IMPROVEMENTS IN HIV COUNSELING AND TESTING SERVICES ON A LARGE UNIVERSITY CAMPUS IN DURBAN, SOUTH AFRICA

Benjamin I. Bearnott^{1,2}; Nomonde Magantolo³; Ayesha B. Kharsany².
¹Massachusetts General Hospital, Boston, MA; ²University of KwaZulu Natal, Durban, South Africa; ³University of KwaZulu Natal, Durban, South Africa. (Tracking ID #1923142)

BACKGROUND: HIV counseling and testing (HCT) is a requisite gateway to evidence-based prevention and treatment strategies. Despite high levels of knowledge about HIV and modes of transmission, many individuals in South Africa remain untested. In a 2009 report from the South African Higher Education HIV & AIDS Programme, 58 % of higher education students in the South African province of KwaZulu Natal (KZN) have never been tested for HIV. On one flagship university campus, HCT had fallen to just a 312 students at the campus clinic in 2011, approximately 1 % of the student body. With the high prevalence of HIV in the overall KZN community and low levels of HIV status knowledge by university students in KZN, this implementation science project was designed to increase the number of individuals accessing HCT in a tertiary education setting, and to help identify subsequent health services they require.

METHODS: The University of KwaZulu Natal HIV/AIDS Programme provides an integrated package of counseling, testing, and treatment services for university students and staff on all UKZN campuses. In 2012, we designed and implemented a multi-faceted improvement project to encourage students and their networks of friends to get tested for HIV on the Howard College UKZN campus. This included implementation of drop-in testing not requiring an appointment, peer educator sessions led by university students on student requested topics, and a Value in Prevention (VIP) communications campaign organized around weekly HIV testing events in the centrally-located campus center. The study protocol was approved by the Biomedical Research Ethics Committee of the Nelson R. Mandela School of Medicine, Faculty of Health Sciences, UKZN.

RESULTS: In the first 14 weeks of this program, 1,279 students and faculty received HCT services at 3 separate locations on campus. This represents a 4-fold increase in the number of individuals tested on the university campus in the whole of 2011. Twenty-seven individuals were newly diagnosed with HIV (seroprevalence 2.1 %). Of a sample of 298 students surveyed, 252 (85 %) were seen by a counselor in less than 15 min after arriving, and 298 (100 %) received HIV testing after pre-test counseling. Ninety-five individuals (31.8 %) were referred to HCT by a friend. The most common requests for further services were for contraception/pregnancy testing, further STI testing and treatment, and medical male circumcision.

CONCLUSIONS: HIV testing uptake spiked dramatically when HCT services were implemented in a manner that was driven by student preferences. HIV prevalence was found to be low in this community, representing an important site for scaling up of HIV prevention interventions. As a result of this preliminary work, the university has committed to employ counselors to provide drop-in HCT at the campus clinics and

HIV Support Units at each of the university's undergraduate and graduate campuses. Further work is needed to harness peer-recruitment strategies and social networks to bring higher risk students and their sexual partners for HIV prevention and testing.

TC/HDL AND LDL/HDL RATIOS ARE BETTER MEASURES FOR CHOLESTEROL MONITORING ASSESSMENT

Osamu Takahashi^{1,2}; Sachiko Ohde¹; Gautam A. Deshpande¹. ¹St. Luke's Life Science Institute, Tokyo, Japan; ²St. Luke's International Hospital, Tokyo, Japan. (Tracking ID #1940025)

BACKGROUND: Cholesterol screening is important to identify those at risk of cardiovascular disease. Little information is available on subsequent monitoring including frequency and timing of re-screening and optimal measure to use. We aimed to estimate the long-term between-person variation ("signal") and short-term within-person variation ("noise") of the different lipids measures and evaluate the best measure and the optimal interval for lipid re-screening.

METHODS: We conducted a retrospective cohort study from 2005 to 2008. We enrolled all people consecutively admitted to our Centre for Preventive Medicine for the health checkup program at St. Luke's International Hospital in Tokyo, Japan. Annual measurement of the serum total cholesterol (TC), low-density lipoprotein (LDL) cholesterol, high-density lipoprotein (HDL) cholesterol, non-high-density lipoprotein (non-HDL) were measured, calculating TC/HDL and LDL/HDL ratios. We estimated the ratio of "signal" to "noise" for each measure adjusting for age, gender, and body mass index (BMI) using random-effect model.

RESULTS: 15,810 apparently healthy Japanese adults not taking cholesterol-lowering medications at baseline had annual check-ups over 4 years. The mean age of participants was 49.3 years old (SD: 12.2, range: 21 to 92) and 53 % of patients were male; mean BMI was 22.5 kg/m² (SD: 3.2). Average TC level at baseline was 204 mg/dl (SD, 34 mg/dl). Short-term within-person variations of TC, LDL, non-HDL, HDL, TC/HDL, and LDL/HDL were 186 (coefficient of variation (CV), 6.7 %), 137 (CV: 10 %), 154 (CV: 8.8 %), 27 (CV: 8.3 %), 0.09 (CV: 8.5 %) and 0.06 (CV: 12 %), respectively. The ratio of signal to noise at 3 years was largest for TC/HDL (1.1), followed by LDL/HDL (1.1), non-HDL (0.86), LDL (0.70), TC (0.65), and HDL (0.53), suggesting that cholesterol ratios are more sensitive for re-screening than single measures.

CONCLUSIONS: The signal-to-noise ratios of standard single lipid measures (TC, LDL, non-HDL and HDL) are weak over 3 years and decisions based on these measures are potentially misleading. The ratios, TC/HDL and LDL/HDL, appear to be better measure for monitoring assessments. The lipid re-screening interval should be greater than 3 years for those not on cholesterol-lowering drugs.

TEAM HUDDLES AS WORKPLACE LEARNING OPPORTUNITIES: AN OBSERVATIONAL STUDY

Bridget OBrien¹; Terry Keene²; Rebecca L. Shunk^{1,3}.
¹Univ of California, San Francisco, San Francisco, CA; ²San Francisco VA Medical Center, San Francisco, CA; ³San Francisco VA Medical Center, San Francisco, CA. (Tracking ID #1939002)

BACKGROUND: Team huddles, or brief meetings at the beginning of clinic among team members, are recommended as a key element of high functioning primary care teams. Huddles seem like a straightforward communication process to coordinate patient care, but as a hub for teamwork they require many of the same complex interpersonal and communication skills associated with teamwork in other contexts. In an era when much emphasis is placed on training for interprofessional collaboration and team-based care, we identified team huddles as a potential site for workplace learning related to teamwork. In this study, we identify and describe learning opportunities afforded by team huddles.

METHODS: We conducted an observational study of five academic primary care teams in a San Francisco VA primary care clinic from July to December, 2013. Team huddles include an internal medicine resident, nurse practitioner student, registered nurse (RN), licensed vocational nurse (LVN), clerk, and, on some teams, a psychologist, pharmacist, or social worker. A huddle coach (an MD or NP preceptor) also attends the huddle on a regular basis. Huddles are scheduled for 15 min once or twice per week. One investigator conducted all 52 observations and documented verbal and non-verbal communication in each huddle. The study team analyzed the data using a grounded theory approach. During the open coding phase, we independently identified examples of learning opportunities (content and who initiated the opportunity) and then discussed these to achieve consensus understanding. After reviewing and discussing 5 notes, we reviewed a consolidated list of all learning opportunities and developed a set of categories which we then used to code

all notes. In the axial coding phase we looked for patterns within and across teams as well as over time.

RESULTS: We found learning opportunities in six content areas: people (learning about colleagues and patients), clinical (disease and diagnostic processes, medications), relationships (skills such as support, negotiation), team process (schedules, how to communicate, leadership), systems (how things get done), and the organization (how things work in the VA). Most of these opportunities occurred unintentionally and spontaneously, through routine huddle dialogue initiated by various team members such as raising questions, explaining a process or situation, and problem solving. The main exception was coaches. Coaches tended to create intentional, explicit learning opportunities by providing feedback to the team, modeling communication strategies, and raising questions that prompted discussion / clarification among the team. The majority of the content focused on systems issues. Earlier in the year, when residents and NP students were newer to clinic, this content prompted explanations by the coach or RN. As the year progressed, some teams shifted toward problem-solving discussions of systems issues that afforded more collaboration among the team.

CONCLUSIONS: Team huddles offer a rich array of learning opportunities related to systems issues and teamwork. While much may be learned implicitly, simply by participating in a huddle, coaches can enhance the learning opportunities by providing feedback and suggestions on team communication and team process.

TEAM INTERACTIONS DURING COACHING SESSIONS: A WINDOW INTO TRANSFORMATION TO A PCMH TEAM-BASED CARE MODEL

Molly Harrod¹; Jane Forman¹; Claire Robinson¹; Adam Tremblay^{2,3}; Leo Greenstone^{2,3}. ¹VA Ann Arbor Health Care System, Ann Arbor, MI; ²VA Ann Arbor Health Care System, Ann Arbor, MI; ³University of Michigan, Ann Arbor, MI. (*Tracking ID #1938830*)

BACKGROUND: The Patient Centered Medical Home (PCMH) model of care delivery requires transformation from physician-centric to team-based care. This transformation requires fundamental changes in staff roles and relationships. Although prior research has looked extensively at team functioning and effectiveness, little has been done to understand the process of becoming a team. This study looks at a training approach (i.e. coaching sessions) that is being used in a large Veterans' Health Administration primary care clinic to educate and support teams in the redesign of their work in order to meet PCMH goals (e.g., open access, continuity, and care coordination). We documented changes in how team members interacted and related to one another during coaching sessions in order to gain insight into the process of these transformations.

METHODS: Coaching sessions were conducted with individual teams, which consisted of a physician(s), a nurse case manager, a licensed practical nurse and a medical clerk, and was led by an assigned primary care provider who was not the provider on the team being coached. Each team was required to meet 1–2 times a month for a total of two hours per month. Nine out of 20 health care teams were longitudinally observed during their coaching sessions (25+ hours) from May 2013 to December 2013. Conversations and interactions (including nonverbal body language) were recorded via hand-written field notes. A grounded approach was used to analyze the data focusing on the interactions between team members. Codes were then categorized into themes.

RESULTS: Over the period of observation, team members began to relate to one another in new ways that included understanding one another's developing role within the team, advocating for one another, and affirming to one another that they were doing a good job in the midst of complex primary care redesign. In addition, non-physician team members taught physicians about organizational processes that affected PACT implementation, and physicians openly admitted that they needed help from other team members to figure out how to improve team processes and functioning. These elements of relationship-building indicated a flattening of the existing physician-centric hierarchy. As a result, team members gradually shifted to a more team-based identity in the midst of building new work processes and identifying their roles within these processes.

CONCLUSIONS: We observed that teams engaged in relationship-building during coaching sessions while participating in practice redesign to meet PCMH goals such as open access and increased continuity. Understanding how team members interact and construct these relationships is important so that this aspect of PCMH transformation can be facilitated and supported. Teams need the time to interact in order to create the shared meanings that will define them as a team, and to facilitate their ability to redesign work processes to improve provision of patient-centered care

TELEPHONE MEDICINE IN AN URBAN AMBULATORY INTERNAL MEDICINE RESIDENT CLINIC: A NEEDS ASSESSMENT Katherine A. Wang¹; Andrew Coyle¹; Linda DeCherrie^{1,2}. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Icahn School of Medicine at Mount Sinai, New York, NY. (*Tracking ID #1930440*)

BACKGROUND: In the age of the patient-centered medical home, triage and management of urgent and chronic conditions by telephone are essential components of comprehensive care that limits unnecessary ED visits and hospitalizations. For both primary care physicians and specialists, the ability to evaluate a patient without the benefit of face-to-face interaction is an essential skill. At Mount Sinai Hospital, Internal Medicine (IM) residents on ambulatory rotations respond to patient phone calls. Common calls include urgent overnight complaints, lab alert values, medication refills and visiting nurse reports. While many of these complaints can be managed safely over the phone, residents receive minimal training in telephone medicine. The objective of this study was to assess perceived gaps in resident training and attitudes about telephone medicine.

METHODS: A 16-question online survey to assess resident comfort level and attitudes toward telephone medicine was offered to 139 Internal Medicine residents (PGY1–3), all of whom respond to patient telephone calls while on ambulatory rotations. A parallel 11-question survey was offered to 21 ambulatory IM attending physicians who supervise resident telephone calls. Both surveys included Likert-scale and open-ended questions addressing themes of 1) confidence, 2) quality, 3) attitudes, and 4) communication with faculty and patients (via MyChart, an online communication portal for patients). Participation was voluntary and no compensation was offered to respondents. Results are reported as descriptive data.

RESULTS: 50 residents (19 PGY1, 17 PGY2, and 14 PGY3, with a 36 % response rate) and 6 attending physicians (29 % response rate) completed the survey online. Reported urgent patient calls included abnormal lab values, elevated blood pressure, and symptoms such as chest pain, bleeding, and diarrhea. Fifty-eight percent of residents stated they had never received any telephone medicine training. The majority of residents (68 %) endorsed feeling confident managing patient care over the phone and most (62 %) felt they have adequate resources and support for handling patient calls. Despite this, 50 % of residents disagreed or strongly disagreed with the statement "I feel I am able to provide good care over the phone." All faculty respondents felt that residents provide high quality care over the telephone and agreed with resident management "most of the time." Residents reported conflicting attitudes about telephone medicine; the majority (76 %) note that being available by telephone at night is important for patient care, yet only 34 % feel that providing telephone care is rewarding. Regarding communication, 52 % of residents who cover overnight calls did not feel comfortable contacting faculty overnight. However, 83 % of attendings reported that residents do not contact them enough and no attendings reported being contacted too frequently. All faculty reported providing feedback to a resident; however, only 18 % of residents reported ever receiving feedback. Although 74 % of residents feel that MyChart is a good way to communicate with some patients, only 8 % use it. The most commonly cited reasons for not using it were 1) lack of training, 2) concerns about patient interest and access, and 3) barriers with resident schedules. Areas identified by both residents and faculty for improvement include clarification about resident responsibilities, training about responses to common calls, basic telephone communication and triage skills, improved resident-faculty communication, and MyChart training.

CONCLUSIONS: This study assessed resident and faculty attitudes toward and training gaps in IM resident telephone medicine training. While most residents feel that telephone medicine is an important facet of patient care and feel confident about managing telephone complaints, there are gaps in training and weaknesses in the current system. Both residents and faculty identified a desire for increased communication overnight, more feedback, and strict criteria prompting an attending call or ED referral. Limitations of this study are the fairly low response rate and that many of the expressed attitudes may be specific to this resident clinic. The lack of training and perceived inability to deliver high quality care reveal the need for a revised, standardized approach to telephone medicine training in an IM resident ambulatory clinic.

TEXT MESSAGING HOTLINE: AN INNOVATIVE AND EFFECTIVE WAY TO COMMUNICATE SEXUAL HEALTH INFORMATION TO TEENAGERS Molly A. Fisher¹; Kate E. Lucey²; Steven Federico³; E. Bimla Schwarz¹. ¹University of Pittsburgh Medical Center, Pittsburgh, PA; ²Northwestern University, Chicago, IL; ³University of Colorado, Aurora, CO. (*Tracking ID #1936897*)

BACKGROUND: Many teens lack access to reliable information about sexual health. As text messaging is the most utilized form of communication among teens,

we examined Colorado teenagers' use of a texting hotline, In Case You're Curious (ICYC), which provides evidence-based responses to sexual health questions.

METHODS: ICYC was created as an anonymous sexual health texting hotline, and marketed to adolescents in Denver, Colorado. Local health education organizations distributed business cards and other marketing tools to teens who participated in after school programming and attended community clinics. Text messages sent to the hotline were received by a third party website, which assigned an identification number to each phone number so that the users would remain anonymous. The questions were then answered by a college-educated health educator, using a database of thousands of medically-accurate 160 character responses. The questions in the database were developed from teen question and answer websites and refined by focus groups. The responses were developed by medical students and reviewed by a physician. The hotline was available 24 h per day, 7 days per week. We used a web-based tool to collect data regarding text questions and responses sent between September 2010 and October 2012. Descriptive statistics were used to assess the number of text messages received per month, the types of questions users submitted, the number of users who submitted questions, and the average number of text questions per user.

RESULTS: During the study period, ICYC received 3,777 text messages from 1,121 users. Between the program's first and second year, the number of text messages increased from 1,092 to 2,656. During the first year, an average of 2.76 text messages were sent per day, compared to 6.69 text messages per day the second year. More text messages were sent during the school year (317/month) than during the summer months (208/month), and more were sent during weekdays (594/day) than weekends (403/day). Almost half (48 %) of users texted more than one question to the hotline. The most frequent texted questions were about definitions, risk, and consequences of sexual acts (21 %), pregnancy (15 %), sexually transmitted infections (STIs) (11 %), Birth control (10 %), female body/puberty (9 %), male body/puberty (9 %), sexual orientation (6 %), masturbation (5 %), relationships (2), and safety (1 %). The remaining 25 % were about clinic referrals among other topics. ICYC's response time improved over time; responses were generally provided in less than 4 h, and always within 24 h.

CONCLUSIONS: Texting hotlines offer an innovative and actionable way to provide teens with timely access to evidence-based sexual health information on an as needed basis.

THE ASSOCIATION OF FOOD INSECURITY AND DIABETES CONTROL AMONG LOW-INCOME INDIVIDUALS Julie B. Silverman^{1,2}; Jim Krieger^{3,4}; Meghan M. Kiefer^{2,1}; Paul Hebert^{1,2}; Nathan Drain³; June Robinson³; Leslie Taylor³; Janet Kapp³; Karin M. Nelson^{1,2}. ¹VA Puget Sound Healthcare System, Seattle, WA; ²University of Washington, Seattle, WA; ³Seattle King County Public Health, Seattle, WA; ⁴University of Washington, Seattle, WA. (*Tracking ID #1937147*)

BACKGROUND: Food insecurity is defined as the lack of dependable access to adequate, safe and nutritious foods necessary for a healthy and active life. Although there is an abundance of literature examining the relationship between diet and health, research on the health consequences of food insecurity is surprisingly limited. Only a few studies have demonstrated an association between food insecurity and glycemic control. The objective of this study was to evaluate the relationship between food insecurity and glycemic control among individuals with diabetes and to explore potential mediators of this association.

METHODS: We conducted a secondary analysis of baseline data from 287 low-income patients with poorly controlled type 2 diabetes (HbA1c >=8 %) who were enrolled in the Peer Support for Achieving Independence in Diabetes (Peer-AID) trial, a randomized controlled study evaluating a diabetes self-management intervention delivered by community health workers. We evaluated the differences in socio-demographic and clinical characteristics, including glycemic control, between food-secure individuals and those struggling with food insecurity (based on the USDA's 6-item Food Security Survey Module). We used multivariable linear regression to model the relationship between glycemic control and food insecurity, adjusting for age, gender, race, language, education, marital status and BMI. Diabetes-related distress (moderate distress defined by a score of 2 or more on Polonsky's Diabetes Distress Scale), depression (depression defined by a score of 5 or more on the PHQ-8) and medication adherence (low medication adherence defined by a score of less than 6 on the Morisky Scale) were evaluated as potential mediators.

RESULTS: The prevalence of food insecurity was 47.4 %. Compared to food-secure participants, participants with food insecurity were more likely to be female (59.6 % vs. 39.1 %, *p*=0.001), non-white (66.9 % vs. 44.4 %, *p*<0.001), speak only English at home (59.6 % vs. 46.4 %, *p*=0.025), be unmarried or single (68.4 % vs. 45.7 %, *p*<0.001) and be obese (68.4 % vs. 50 %, *p*=0.001). Food-insecure participants utilized

the health care system more frequently in the past year, with increased physician visits (10.7 vs. 7.3, *p*<0.001) and a higher percentage using the emergency department (42.7 % vs. 31.1 %, *p*=0.04). Although all subjects had poor glycemic control, food-insecure individuals had significantly higher hemoglobin A1c levels (9.4 vs. 8.8, *p*=0.003 unadjusted; 9.4 vs. 8.8, *p*=0.002 adjusted). They also had a higher incidence of hypoglycemic episodes in the past year (57.7 % vs. 45.2 %, *p*=0.04). Forty percent of the food-insecure individuals who experienced hypoglycemia attributed it to not being able to afford food, compared to none of the food-secure individuals. Food-insecure participants had increased distress regarding their diabetes care (55.1 % vs. 33.7 %, *p*<0.001), a greater prevalence of depression (74.1 % vs. 35.6 %, *p*<0.001) and lower medication adherence (52.9 % vs. 37.2 %, *p*=0.02). After adjusting for these potential mediators, the A1c levels of food-insecure individuals remained significantly higher than those of food-secure individuals (9.4 vs. 8.7, *p*=0.002).

CONCLUSIONS: Food insecurity is associated with poorer glycemic control among low-income individuals with diabetes. Given that 1 in 6 households was food insecure during 2012, food insecurity is not an inconsequential concern. Assessing food security status and addressing patients' food needs may be an effective, non-pharmacological intervention to improve glycemic control in low-income individuals with poor diabetes control.

THE BURDEN OF PRE-DIABETES AMONG OBESE VETERANS: UNDERSTANDING THE PREVALENCE OF DISEASE AND MERITS OF ROUTINE SCREENING PROGRAMS Tannaz Moin^{1,2}; Fatima Makki³; Jane E. Weinreb²; Nanette Steinle^{4,5}; Charles J. Billington^{6,7}; Kathryn Havens⁸; William Yancy^{9,10}; Mathew L. Maciejewski^{9,10}; Laura Damschroder³; Caroline R. Richardson^{11,12}. ¹VA Greater Los Angeles HS&D Center for Healthcare Innovation, Los Angeles, CA; ²VA Greater Los Angeles Healthcare System, Los Angeles, CA; ³Ann Arbor VA Center for Clinical Management Research, Ann Arbor, MI; ⁴VA Baltimore Healthcare System, Baltimore, MD; ⁵University of Maryland, Baltimore, MD; ⁶Minneapolis VA Healthcare System, Minneapolis, MN; ⁷University of Minnesota, Milwaukee, MN; ⁸Zablocki VA, Milwaukee, WI; ⁹Duke University Medical Center, Durham, NC; ¹⁰Durham VA, Durham, NC; ¹¹VA Diabetes QUERI, Ann Arbor, MI; ¹²University of Michigan, Ann Arbor, MI. (*Tracking ID #1939081*)

BACKGROUND: Type 2 Diabetes is a preventable disease. Individuals with pre-diabetes can reduce their risk of developing diabetes substantially by improving their diet, increasing their daily physical activity and losing a modest amount of weight. VA/DoD Clinical Practice Guideline (CPG), Centers for Disease Control (CDC), and American Diabetes Association (ADA) all recommend screening for diabetes in high risk patients, and the same tests used to screen for diabetes can also be used to detect pre-diabetes. Veterans with a BMI>30 or >25 with other cardiovascular risk factors, many of whom have already been diagnosed with diabetes, are eligible to participate in a group lifestyle program called MOVE! The MOVE! program does not directly address diabetes prevention. While not all veterans who may have pre-diabetes are eligible for MOVE!, those who are referred to MOVE! represent a high risk group. Targeting these veterans for screening may be an efficient way to identify a significant number of veterans with pre-diabetes. Because of the lack of systematic screening, the incidence of pre-diabetes among veterans referred to the MOVE! program is not known. In an effort to decrease incident diabetes among veterans, the Diabetes Quality Enhancement Research Initiative (QUERI) partnered with the VHA National Center for Health Promotion and Disease Prevention (NCP) and clinical investigators from 3 VA sites to implement systematic screening for pre-diabetes, to estimate the prevalence of pre-diabetes among veterans referred to MOVE!, and to test the feasibility of delivering diabetes prevention focused lifestyle change programs to veterans with pre-diabetes.

METHODS: The VA Diabetes Prevention Clinical Demonstration Project (VA DPP) was implemented at three geographically dispersed medical centers beginning in January 2012. All veterans referred to MOVE! or presenting for a MOVE! orientation session who did not already have a diagnosis of diabetes were encouraged to complete a screening hemoglobin A1c (HbA1c) test. Patients were classified as pre-diabetic if their HbA1c value was between 5.7 and 6.4 % with no known history of diabetes and no use of anti-glycemic medications including metformin. All patients were informed of their HbA1c test results and pre-diabetic patients were systematically assigned to either a MOVE! group class or to a diabetes prevention group class.

RESULTS: Prior to the demonstration, diabetes screening was inconsistent across the 3 clinical sites. None of the sites were routinely conducting diabetes screening for obese Veterans referred to MOVE!. Automated screening programs were subsequently implemented to ensure screening tests were conducted consistently across the sites in accordance with national recommendations. A total of 1528 obese Veterans were referred to MOVE! between August 2012-November 2013 across the sites. Among

these, 23 % ($n=358$) had a HbA1c value that was consistent with pre-diabetes. Veterans with pre-diabetes had a mean age of 58.6 years (SD 10.2) and BMI of 34.1 (SD 5.7).

CONCLUSIONS: Almost one quarter of veterans referred to the VA MOVE! program have pre-diabetes and are at high risk for developing diabetes. To our knowledge this is the first study to examine screening practices and the prevalence of pre-diabetes among Veterans in multiple VA sites. Screening veterans referred to MOVE! can efficiently identify a significant number of veterans with pre-diabetes. However, the high prevalence of diabetes among MOVE! patients suggests that by waiting until veterans have been referred to MOVE! to screen for pre-diabetes, we may be missing the opportunity to intervene early enough to prevent diabetes in many veterans. While these veterans already have access to a lifestyle change program, it is not a program that specifically addresses diabetes prevention. Optimizing MOVE! for veterans with pre-diabetes or alternatively providing diabetes prevention specific interventions for these veterans may significantly reduce incident diabetes among veterans.

THE CARE TRANSITIONS INNOVATION (C-TRAIN) FOR SOCIOECONOMICALLY DISADVANTAGED ADULTS, RESULTS OF A CLUSTERED RANDOMIZED CONTROLLED TRIAL Honora Englander¹; LeAnn Michaels³; Benjamin Chan²; Devan Kansagara^{4,1}. ¹Oregon Health & Science University, Portland, OR; ²Oregon Health & Science University, Portland, OR; ³Oregon Health & Science University, Portland, OR; ⁴Portland VA Medical Center, Portland, OR. (Tracking ID #1935654)

BACKGROUND: Despite growing emphasis on transitional care to reduce costs and improve quality, few studies have examined transitional care improvements in socioeconomically disadvantaged adults. It is important to consider these patients separately as many are high-utilizers, have different needs, and may have different responses to interventions. We performed the Care Transitions Innovation (C-TraIn) study to evaluate the impact of a multi-component transitional care improvement program on 30-day readmissions, emergency department (ED) use, transitional care quality, and mortality.

METHODS: We performed a clustered randomized controlled trial conducted at a single urban academic medical center in Portland, Oregon. We enrolled 382 hospitalized low-income adults admitted to general medicine or cardiology who were uninsured or had public insurance. Participants resided in one of three Portland metro area counties, had to have access to a working phone (friend or shelter phone was okay), spoke English, and had no disabling mental illness (defined as active psychosis or active suicidal ideation). Control patients received usual care, which consisted of: (1) a routine inpatient nurse intake; discharge patient education was performed by inpatient nurses and physicians. (2) medication reconciliation performed by treating physicians. Uninsured patients were financially responsible for post-discharge medications. (3) There was no systematic approach to securing post-discharge follow-up. Patients without a usual source of care were often given a list of 14 area safety-net clinics, which have limited capacity for uncompensated care. Prior work showed that uninsured—and to a lesser degree Medicaid—patients have difficulty establishing primary care and frequently cannot access appointments or navigate the complex system. Any coordination of post-discharge services was performed by inpatient care managers, social workers and treating physicians with no formal community linkages. C-TraIn patients received a multi-component intervention which was delivered in addition to usual care, and included (1) transitional nurse coaching and education that started early in hospitalization and lasted for 30 days post discharge, often including home visits for highest risk patients; (2) pharmacy care, including medication reconciliation, low health literacy education, and provision of 30 days of medications after discharge for those without prescription drug coverage; (3) post-hospital primary care linkages, including establishing new outpatient linkages for those without a usual source of care; and (4) systems integration and continuous quality improvement that convened a multidisciplinary team across in- and outpatient care. Primary outcomes included 30-day inpatient readmission and ED use. Readmission data for all participants, including the uninsured, were obtained using a hospital administrative database that includes admissions from all Oregon and southwest Washington hospitals. Secondary outcomes included quality (3-item Care Transitions Measure) and mortality. Research staff administering questionnaires and assessing outcomes were blinded.

RESULTS: Of the 2290 patients screened, 522 were eligible and 382 enrolled (209 to intervention, 173 control). Of those enrolled, 293 (76.7 %) completed a follow-up phone survey 30 days after index discharge. Intervention and control groups were

well matched and there were no significant differences between the groups. Among intervention patients, 49.7 % (104/209) received a home visit and 92.8 % (194/209) received an inpatient pharmacy consultation. New primary care linkages were established in 42.1 % of patients (88/209), including 68.7 % (68/100) uninsured and 16.8 % (20/119) publicly uninsured patients. There was no significant difference in 30-day readmission between C-TraIn (30/209, 14.4 %) and control patients (27/173, 16.1 %); $p=0.644$ or in ED visits between C-TraIn (51/209, 24.4 %) and control (33/173, 19.6 %); $p=0.271$. C-TraIn was associated with improved transitional care quality and mortality. 47.3 % (71/150) of C-TraIn patients reported a high quality transition compared to 30.3 % (36/119) control patients; odds ratio 2.17 (95 % CI 1.30–3.64). Zero C-TraIn patients died in the 30-day post-discharge period compared with 5 in the control group ($p=0.019$).

CONCLUSIONS: C-TraIn did not reduce 30-day inpatient readmissions or repeat ED use; however, it improved quality and was associated with improved mortality. Our findings raise questions as to the preventability of readmissions through traditional bridging transitional care improvements among socioeconomically vulnerable adults, many of whom had limited access to care prior to hospitalization. Most health systems interested in transitions of care are seeking a business case. While reducing readmissions is often the centerpiece, care quality and patient experience are important to consider.

THE CHAOTIC PRACTICE ENVIRONMENT IN VA PRIMARY CARE CLINICS: NATIONAL SURVEY Mark D. Schwartz^{1,2}; Danielle Rose³; Katelyn Bennett^{1,2}; Elizabeth M. Yano^{3,4}. ¹VA New York Harbor Healthcare System, New York, NY; ²NYU School of Medicine, New York, NY; ³VA Greater Los Angeles Healthcare Center, Sepulveda Campus, Los Angeles, CA; ⁴UCLA, Los Angeles, CA. (Tracking ID #1938465)

BACKGROUND: A chaotic practice environment may adversely impact physicians and diminish the quality of care they provide. As part of the VA Clinical Practice Organizational Survey (CPOS), designed to assess organizational traits of VA facilities, we sought to determine the pace of work at VA primary care (PC) clinics and compare the characteristics of clinics perceived as chaotic versus non-chaotic.

METHODS: The 2007 CPOS surveyed the PC Directors at all VA PC clinics with 4,000 or more patients and 20,000 or more annual outpatient visits. The questionnaire asked practice leaders to describe the pace of their PC practice environment on a 5-point scale where 1 = calm; 3 = busy but reasonable; and 5 = hectic or chaotic. We defined clinics rated as 4 or 5 as “chaotic.” In addition to practice pace, the CPOS also assessed organizational practice characteristics including resources, staff, and performance barriers. Data on clinic-level characteristics were collected from CPOS 2007: e.g., VA Medical Centers (VAMC) or community-based outpatient clinics (CBOC), and % minority patient population; and area-level characteristics were collected from the Area Resource File (2008): i.e., urban vs. rural location, and % in poverty. In bi-variate logistic regressions, we tested for associations between chaotic clinics with organizational characteristics of practice stress level, patient flow bottlenecks (7-item scale); use of computerized reminders in the medical record (15-item scale); perceived barriers to improving facility performance (12-item scale); sufficient PC staff (10-item scale); sufficient PC resources and space (9-item scale); and unfilled vacancies (4-item scale). We also tested for associations between chaotic clinics with clinic and area level characteristics.

RESULTS: 225 (90 %) of 250 VA PC clinics surveyed responded. 130 (57.8 %) reported their practice environment as chaotic. Sixty percent of chaotic clinics were described as having high overall stress vs. 9 % of calm or busy clinics ($p<0.001$). The associations of chaotic clinics with practice characteristics are summarized in Table 1.

CONCLUSIONS: Most VA PC Directors describe their practice environment as chaotic and under high stress. Chaotic clinics are more likely to have high stress levels, patient flow bottlenecks, barriers to improving performance, fewer computerized reminders, insufficient staff and resources, and more unfilled vacancies. Clinic chaos was not linked to facility type, patient demographics or clinic location. Clinic chaos may serve as a simple measure of the health of a practice, a measure of distress among clinic staff, and a marker for a vulnerable practice. Future studies should evaluate how chaotic clinics effect patient experience and outcomes as well as staff outcomes. Since this study, VA has transformed PC clinics into medical homes (Patient Aligned Care Teams, PACT), which has the potential to reduce chaos and stress. Further research is needed to understand how the implementation of the VA PACT model has impacted chaos in PC clinics and how chaos has influenced PACT implementation.

Table 1: Characteristics of Chaotic VA PC Clinics

Practice Characteristics	Odds Ratio	95 % Confidence Interval	P Value
Organizational Characteristics			
Practice stress level	2.05	1.31, 2.78	<0.0001
Bottlenecks to patient flow	1.21	1.11, 1.34	<0.0001
Computerized clinical reminders	0.92	0.84, 0.99	0.05
Barriers to improving performance	1.12	1.06, 1.17	<0.0001
Sufficient staff	0.92	0.88, 0.96	<0.0001
Sufficient resources	0.92	0.89, 0.95	<0.0001
Unfilled vacancies	1.10	1.03, 1.18	0.006
Clinic-level characteristics			
153 VAMC (vs. 97 CBOC)	1.15	0.67, 1.98	0.61
Minority patients	20.28	0.85, 481.31	0.06
Area-level characteristics			
Metropolitan location (urban)	0.91	0.61, 1.36	0.65
Percent in poverty	1.02	0.95, 1.08	0.64

THE COLOR PURPLE: MAINTAINING PATIENTS' WISHES Adam Lammly; Vishal Patel; Nicholas Merritt. Christiana Care Health System, Newark, DE. (Tracking ID #1934758)

BACKGROUND: In 2007, the Society of Hospital Medicine published a study on the lack of standardization of DNR (do not resuscitate) practices across the country. Of the 127 nursing executives, 75 of the respondents recalled situations of confusion pertaining to patient care when "do not resuscitate" (DNR) orders were involved. At our institution, during a 6 month period there were two code blues called and performed on hospital inpatients with a DNR order on their charts in the hemodialysis unit and Gastroenterology (GI) lab. This highlights that miscommunication when patients are transferred or handed off can lead to serious medical errors, poor patient outcomes, and increased unnecessary costs—all deviating from patient-centered care.

METHODS: A multidisciplinary task force was created to standardize the system to identify DNR status for inpatients when transferred to other units. Initially begun in the hemodialysis unit, the task force first met with nursing supervisors and also surveyed all the hemodialysis staff to determine how they determined patients' DNR status. Concurrently, an educational seminar was provided to all staff members about DNR status/implications. The primary intervention proposed was placing a purple sticker on the top of the hemodialysis flow sheet upon initiation of the dialysis for that day if the patient had a DNR order listed in the electronic medical record. This flow sheet/purple sticker is visible by all staff especially if standing in the middle of the unit. Once implemented, there was a 2 week chart audit period to ensure the validity of this process.

RESULTS: During the initial study of 31 dialysis sessions over 2 weeks, 380 charts were reviewed and the staff correctly identified all 10 patients with DNR status. This program has continued for the past 9 months, with an average of 20 patients with DNR status receiving inpatient hemodialysis each month. This program has now been adopted by the GI lab and another hemodialysis unit at another hospital in the health care system. Since implementing this program, there have been zero code blues on patients with DNR status in these units. In addition, the flow sheet has been redesigned to include a specific area for this sticker, providing another reminder to verify patients' code status.

CONCLUSIONS: This study showed that a small, inexpensive intervention can reduce inappropriate care and unnecessary health care costs, and more importantly, increase adherence to patients' end of life decisions. Collaborating with multiple disciplines within the institution provided the foundation to enact change. A simple process of correctly identifying patients' end of life wishes with a purple sticker on the patients' bedside paperwork is now being tested in all other ancillary services (imaging departments, rehabilitation services) in hopes of having ZERO inappropriate codes for all patients with DNR orders.

THE DIFFERENCE OF THE CHARACTERISTICS OF NEW PATIENTS VISITING A JAPANESE EMERGENCY HOSPITAL BETWEEN AT NIGHT AND DAYTIME: A CROSS-SECTIONAL STUDY Norio Fukumori¹; Hitoshi Eguchi^{2,3}; Jun Tokutomi³; Yuka Naito³; Yuta Sakanishi¹; Shu-ichi Yamashita³; Takashi Sugioka¹. ¹Community Medical Support Institute, Faculty of Medicine, Saga University, Saga, Japan; ²Saga Memorial Hospital, Saga, Japan; ³Saga University Hospital, Saga, Japan. (Tracking ID #1942113)

BACKGROUND: Medical services have been changed to accommodate the needs of patients with increased diversity of life styles by changing the system such as prolongation of office hours. Although prolongation of office hours may facilitate the visit of younger patients, the actual influence of it remains to be investigated. In this study we investigate the difference of the characteristics of new patients visiting a Japanese emergency hospital between at night (N) and daytime (D).

METHODS: 3,341 of new patients visited the department of internal medicine of Saga memorial hospital, an emergency hospital in Japan on 2010. Five hundred patients were randomly selected from all new patients. The characteristics of the patients including sex, age, the date of the visit, specialties of the doctors, with/without of referral from other medical clinics, to be taken by ambulance car or not, the chief complaint and main diagnosis were reviewed from the medical charts. The chief complaint and main diagnosis of the patient were classified by the ICD-10 code. The difference of characteristics of patients were examined by t-test for continuous variables and chi-square test for dichotomous variables. All statistical analyses were performed using Stata SE version 12.0.

RESULTS: The mean age (SD) of the group D and N were 49.3 (), 33.9 (), respectively ($p<0.001$). The patients D were referred by other clinics more often and visited to the secondary examination of their health check-up. The number of disease associated with pediatrics and orthopedics were larger in the group N. Infectious diseases were most popular in both groups, 56.5 % of which were in the group N.

CONCLUSIONS: The new patients who visited an emergency hospital at night, were younger and tended to have infectious, pediatrics, and orthopedics disease more often. Physician of internal and emergency medicine need versatile ability of medical care not only internal medicine but also pediatrics or orthopedics to care new patients who visit emergency hospital at night.

THE EFFECTIVENESS OF A CASE-BASED CURRICULUM ON INTERNAL MEDICINE RESIDENTS' PERCEPTIONS REGARDING APOLOGY FOR MEDICAL ERRORS Stephen A. McCullough; Meridale Baggett; Victor Chiappa; Hasan Bazari; Paul F. Currier. Massachusetts General Hospital, Boston, MA. (Tracking ID #1930628)

BACKGROUND: The 1999 Institute of Medicine report To Err Is Human focused attention on the importance of medical error disclosure and apologies. Current data support that though medical errors are common, trainees frequently do not disclose or apologize for mistakes. To date, no curriculum to teach internal medicine (IM) residents how to apologize for medical errors has been reported in the literature. A teaching program on apology for medical errors was developed and instituted. A study was undertaken to determine the effect of the curriculum on the perceptions of IM residents.

METHODS: A 3 h curriculum consisting of an introductory lecture and three simulated case scenarios on apology for medical errors was administered to PGY-2 IM residents. A 14-question survey was administered directly pre and post-session to assess (1) resident comfort in apologizing to patients and (2) specific behaviors addressed during the curriculum that residents believe may warrant an apology. The post-session survey contained 8 additional questions regarding the effectiveness of the curriculum. Data were compared using students' two-tailed t test.

RESULTS: 21 PGY-2 internal medicine residents (52 % female) completed the curriculum and 20 (95.2 %) completed both surveys. On a 5-point Likert scale, residents rated agree to strongly agree that the curriculum was relevant (4.6 ± 0.26), helpful (4.35 ± 0.35), informative (4.35 ± 0.35), and that the cases were realistic (4.45 ± 0.32). Residents rated agree that the curriculum helped them analyze situations in which an apology may be necessary (4.4 ± 0.26), determine the appropriate setting to apologize (4 ± 0.5), obtain patients' perceptions regarding their illness (4 ± 0.42), apologize to patients (4.35 ± 0.29), and navigate difficult emotional situations (4.2 ± 0.26). Before and after the curriculum residents rated neutral to agree they were comfortable apologizing (3.76 vs 3.95), and they rated agree to strongly agree that there is value in apologizing (4.6 vs 4.7) and that apologizing strengthened the doctor-patient relationship (4.14 vs 4.25). Residents rated disagree that they feared apologizing (2.85 vs 2.6), and they rated disagree to strongly disagree that apologizing was beyond the scope of their responsibility (1.33 vs 1.45.) Lastly, the curriculum increased the number of residents who would apologize for not maintaining sterile technique during a procedure (19 % vs 65 %, $p=0.002$) and for administering the wrong dose of a medication (80.9 % vs 100 %, $p=0.04$), though there were no differences in other specific behaviors.

CONCLUSIONS: (1) IM residents believe apologizing to patients is largely beneficial, though our curriculum did not change those beliefs. (2) IM residents believe a case-based curriculum on apology is relevant, helpful, and valuable. (3) A curriculum on apology can modify specific resident behaviors.

THE EFFECTS OF A MULTI-FACETED MEDICATION RECONCILIATION QUALITY IMPROVEMENT INTERVENTION ON PATIENT SAFETY: PRELIMINARY RESULTS OF THE MARQUIS STUDY Jeffrey L. Schnipper^{1,2}; Sunil Kripalani⁴; Jason Stein⁵; Tosha B. Wetterneck⁶; Peter Kaboli³; Stephanie Mueller^{1,2}; Amanda Salanitro⁷; Jacquelyn A. Minahan¹; Nyryan V. Nolido¹; Elisabeth Burdick¹. ¹Brigham and Women's Hospital, Boston, MA; ²Harvard Medical School, Boston, MA; ³Iowa City VA Medical Center, Iowa City, IA; ⁴Vanderbilt University Medical Center, Nashville, TN; ⁵Emory University, Atlanta, GA; ⁶University of Wisconsin, Madison, WI; ⁷Vanderbilt University, Nashville, TN. (*Tracking ID #1938437*)

BACKGROUND: Unintentional medication discrepancies during hospitalization can contribute to adverse drug events, resulting in patient harm. Discrepancies can be reduced by performing medication reconciliation; however, effective implementation of medication reconciliation has proven to be challenging. The goals of the Multi-Center Medication Reconciliation Quality Improvement Study (MARQUIS) are to operationalize best practices for inpatient medication reconciliation, test their effect on potentially harmful unintentional medication discrepancies, and understand barriers and facilitators of successful implementation. This analysis focuses on the quantitative results of the two sites that have completed the intervention to date.

METHODS: Five U.S. hospitals are participating in this quality improvement mentored implementation study. Each hospital collected at least 6 months of baseline data ($N=488$ patients) on the primary outcome: the number of potentially harmful unintentional medication discrepancies per patient. This was determined by a trained on-site pharmacist taking a "gold standard" medication history on a random sample of approximately 25 medical-surgical inpatients per month and then comparing this history to their admission and discharge medication orders. Discrepancies were categorized as intentional (based on documentation and by questioning the medical team as needed), those due to errors in the medical team's preadmission medication history, and those due to reconciliation errors (i.e., incorrect orders despite correct medication histories). Trained physician adjudicators at each site then determined the potential for harm of all unintentional discrepancies. With the guidance of trained mentors and using standard quality improvement principles, each site then began to implement one or more of 11 best practices to improve medication reconciliation. Sites were provided with an implementation manual describing these interventions in detail as well as supplementary materials such as instructional videos and slide presentations. Mentors conducted monthly phone calls with local site leaders and made two site visits during the two-year intervention period. Analyses were then conducted to compare discrepancies per patient in patients exposed to any interventions with both pre-intervention controls and concurrent controls using Wilcoxon rank sum test.

RESULTS: The first site to complete the intervention initially chose several interventions to implement, including provider training in taking a "best possible medication history," assessment of patient risk for medication errors, and provision of intensive discharge counseling in high-risk patients. This site also expanded the use of pharmacy technician "medication reconciliation assistants" (MRAs) to take medication histories on admitted patients while still in the emergency department. Towards the end of the study, this site adopted "measure-vention" techniques (where defects in care are identified and corrected in real time) to ensure that patients who hadn't received appropriate interventions subsequently received them while still hospitalized. The rate of discrepancies per patient was 4.49 during the pre-intervention period ($N=126$), 5.24 among 119 concurrent controls, and 3.44 among 127 intervention patients ($p<0.001$ for comparison with both control groups combined). Similarly, rates of potentially harmful discrepancies were 0.25 per patient pre-intervention, 0.32 for concurrent controls, and 0.09 for intervention patients ($p=0.003$ for comparison with both controls). The second site to complete the study chose a similar initial set of interventions to adopt. They did not have an MRA program but obtained institutional support to start one in the future with guidance from the first site. Discrepancy rates were 2.04 during the pre-intervention period ($N=119$) and 2.37 among 93 intervention patients during the first 6 months of the intervention ($p=0.11$). However, discrepancies then rose to 3.81 among 166 patients after adoption of a commonly used electronic medical record (EMR) that actually made it more difficult to document preadmission medications, diffused provider accountability, and made discharge medication instructions less clear ($p<0.001$ for comparison with pre-EMR groups). Similarly, rates of potentially harmful discrepancies per patient rose from 0.35 before to 1.10 after EMR implementation ($p<0.001$).

CONCLUSIONS: Adoption of a multi-faceted medication reconciliation quality improvement initiative using a mentored implementation model has the potential to reduce potentially harmful medication discrepancies. However, external factors, such as EMRs that are not designed and/or implemented optimally, can have adverse effects on these types of patient safety initiatives.

THE EFFECTS OF AGING ON SICKLE CELL DISEASE AND IDENTIFICATION OF POSSIBLE MARKERS FOR INCREASED SURVIVORSHIP Susanna Curtis¹; Zipora Etzion²; Neeraja Danda²; Henny H. Billett². ¹Montefiore Medical Center, Bronx, NY; ²Montefiore Medical Center, Bronx, NY. (*Tracking ID #1938717*)

BACKGROUND: As our understanding of the pathophysiology of sickle cell disease (SCD) has improved, so has our ability to prevent early mortality. Because elderly SCD patients are a relatively new population, little is known about how SCD affects the normal aging process or how aging affects SCD. This study seeks to examine changes in laboratory and clinical parameters associated with aging in SCD and to identify markers of longevity.

METHODS: We used our electronic medical record (EMR) to identify all patients with SCD seen at our facilities in 2012. Patients were identified as having SCD if hemoglobin (Hb) electrophoresis demonstrated sickle hemoglobin (HbS), fetal hemoglobin (HbF) and Hb A2 but no HbA. Patients were divided into two groups, ages 18–39 and 40–89 and demographics noted. The earliest results starting from 1/1/2012 for each of the laboratory and weight parameters were used for assessment. Health care utilization over the entire year was calculated. Life-time prevalence of end organ damage was evaluated. Since our EMR has >10 years data, additional analyses were performed using patients' own matched laboratory values from 9 to 11 years previously. Two-tailed t-tests with unequal variances were used to compare different aged cohorts and two-tailed paired t-tests compared patients to their approximately 10-year younger selves.

RESULTS: In the year 2012, 439 patients with SCD were seen at our institution ranging in ages from 18 to 87; of those, 129 (29 %) were over the age of 40. The older group was more anemic (Hb 8.0 g/dl vs 8.5 g/dl, $p<.005$), had lower absolute reticulocyte counts ($228.5 \times 10^9/L$ vs $289.2 \times 10^9/L$, $p<.00005$) and had less 'dense' cells as demonstrated by MCHC (33.9 g/dl vs 34.4 g/dl, $p<.001$). In agreement with the decreased red cell density, indirect bilirubin levels in the over 40 year cohort were significantly lower (2.0 mg/dl vs 3.1 mg/dl, $p<2.4 \times 10^{-6}$). ALT and AST tests were not significantly different. Neither absolute nor % HbF were significantly different (8.7 % vs 7.3 %, $p=.21$), though the older cohort was less likely to be on hydroxyurea (29 % vs 42 %, $p<.008$). Platelet counts and white blood cell counts were lower in the older cohort (platelet count: $318.9 \times 10^9/L$ in the older vs $375.9 \times 10^9/L$ in the younger group, $p<.00003$, and WBC: $11.0 \times 10^9/L$ vs $12.5 \times 10^9/L$, $p<.02$ respectively). Serum Cr levels were higher (Cr 1.17 mg/dl vs 0.79 mg/dl, $p<.00001$) while weight was not statistically different. Older patients had, as expected, a higher prevalence of end organ damage with more leg ulcers (22 % vs 8 %, $p<.001$) and more documented renal failure (15 % vs 4 %, $p<.002$) though they had a lower prevalence of acute chest syndrome (35 % vs 51 %, $p<.001$). When health care utilization in 2012 was examined, older patients were more likely to go to clinic, (8.6 vs 5.7 visits, $p<.02$) and less likely to go to the emergency room (3.6 vs 5.8 visits, $p<.02$) or be admitted (1.7 vs 2.4 admissions, $p<.02$). Of the 439 patients in the 2012 cohorts, 223 (51 %) of them also had laboratory data in the years 2001–2003. Over the decade, patients significantly lowered their Hb levels (Hb delta: -2.6 , $p<2.4 \times 10^{-13}$), and lowered their MCHC (MCHC delta: -4.7 , $p<3.8 \times 10^{-7}$). Their %HbF decreased (HbF delta: -10.0 %, $p<.0003$). As patients aged, hemolytic parameters increased as evidence by increases in absolute reticulocyte count (delta: $+15.5$, $p<3.8 \times 10^{-7}$) and indirect bilirubin levels (delta: $+0.13$, $p<.05$) with no significant change in direct bilirubin. They were also shown to increase Cr levels (delta: $+0.13$, $p<.01$). A significant change in WBC or platelets was not seen. To assess whether the older group had a survival advantage because they resist the 'natural decline', we examined the degree of change in the older vs the younger cohorts. No significant differences were seen.

CONCLUSIONS: Older SCD patients demonstrate significant differences in laboratory and clinical parameters from both younger sickle cell patients and from themselves approximately 10 years earlier. They are more anemic and have fewer dense cells. They also appear to be accumulating end organ damage, with increasing Cr levels, more renal failure and an increased prevalence of leg ulcers. They have fewer ER visits and fewer admissions and they utilize the clinic more. However, while our entire cohort increased their indirect bilirubin levels and reticulocyte counts over 10 years, the older group in 2012 still had lower indirect bilirubin and reticulocyte counts. In agreement with this is our data demonstrating that, while the entire cohort decreased their HbF levels over a decade, the older group in 2012 had HbF levels equal to the younger group despite being less likely to be on hydroxyurea. We conclude that even minor changes in HbF levels, coupled with less dense cells and what appear to be lower markers of hemolysis, may confer mortality benefit and might be used to predict late mortality in SCD patients.

THE EFFECTS OF FATIGUE ON DRIVING SAFETY: A COMPARISON OF BRAKE REACTION TIMES IN NIGHT-FLOAT AND POST-CALL PHYSICIANS IN TRAINING Theodore Long¹; Paul G. Talusan²; Andrea Halim²; Laura Guliani³; Nicole Carroll³; John Reach². Yale School of Medicine, New Haven, CT; ²Yale School of Medicine, New Haven, CT; ³Boston College, Boston, CT. (*Tracking ID #1931264*)

BACKGROUND: Duty hour changes for resident physicians have fostered a great deal of discussion about post-shift fatigue and driving impairment. Other studies have found a high incidence of motor vehicle collisions among post-call trainees. Using a driving simulator, trainees on heavy call rotations have also been found to have similar impairment to trainees on light-call rotations with a blood alcohol concentration of 0.04 to 0.05 g%. Under current duty hour regulations, moving to night-float systems instead of traditional 28-hour call has been implemented in an effort to improve safety among intern and resident trainees. However, it remains unknown whether night-float systems improve the driving safety of trainees.

METHODS: Internal medicine and orthopaedic surgery trainees were enrolled during a traditional 28-hour call shift or at the beginning of a night-float shift. We defined night-float trainees as those that had worked at least one consecutive night prior to the current night shift, in an effort to study the effects of contiguous night shifts in a row. Brake reaction times were tested using a Vericom driving simulator at the time of enrollment and following their shifts. We calculated average reaction times for each participant, and conducted matched pair t-tests of the pre- and post-shift averages. We also had participants complete the Epworth Sleepiness Scale, and we performed the Wilcoxon Signed Rank test to detect differences pre- and post-shift.

RESULTS: From June 2013 to July 2013, 61 pre-shift simulations were conducted, and 58 post-shift simulations were conducted (28 orthopaedic surgery, 30 internal medicine). Three simulations were excluded from the analysis because no post-shift responses were recorded. We included 24 trainees on night-float rotations (41 %) and 34 trainees on traditional 28-hour call shifts (59 %). The average reaction times for internal medicine trainees were not significantly changed pre- and post-shift ($p=0.763$). There was an increase in reaction times for orthopaedic trainees ($p=0.007$). For trainees on night-float rotations, there was no significant difference pre- and post-shift ($p=0.65$). However, there was an increase in reaction times among trainees on traditional 28-hour call rotations ($p=0.011$).

CONCLUSIONS: In our study of internal medicine and orthopaedic surgery interns and residents, trainees on traditional 28-hour call rotations had worse brake reaction times post-shift, and trainees on night-float rotations had no difference in reaction times post-shift. While the results of our study suggest that driving safety may be improved through the use of a night-float system, this conclusion should not be taken in isolation of other considerations such as educational tradeoffs and increased hand-offs.

THE FINANCIAL COSTS OF IMPLEMENTING ELECTRONIC HEALTH RECORDS IN HOSPITALS Sarah P. Slight^{1,2}; Casey Quinn³; Anthony J. Avery⁴; David W. Bates^{2,5}; Aziz Sheikh^{2,6}. ¹Durham University, Stockton on Tees, United Kingdom; ²Brigham and Women's Hospital, Boston, MA; ³PRMA Consulting Ltd., Hampshire, United Kingdom; ⁴The University of Nottingham, Nottingham, United Kingdom; ⁵Harvard Medical School, Boston, MA; ⁶The University of Edinburgh, Edinburgh, United Kingdom. (*Tracking ID #1932616*)

BACKGROUND: Electronic health record (EHR) systems hold the promise of improving the safety, quality and efficiency of health care.(1) Despite this promise, U.K. hospitals have been slow to implement and adopt such systems.(2) This is due, in part, to the inhibitory cost of EHRs and the uncertainty in relation to whether they can achieve a return on investment. With more and more health care institutions considering implementation of EHR systems worldwide, this study aimed to categorize the costs associated with implementation and the factors that can influence these costs.

METHODS: We conducted a qualitative study to explore the views and perspectives of a diverse range of relevant staff and members of the implementation team at 12 hospitals planning to implement three centrally procured applications i.e., iSOFT's Lorenzo Regional Care, Cerner's Millennium, and CSE's RiO. After obtaining ethical approval, we conducted 41 semi-structured interviews between February 2009 and January 2011. A workable list of main- and sub-themes was developed inductively and applied systematically to these data with the aid of the computerized qualitative data analysis software QSR N-Vivo.

RESULTS: We identified four overarching cost categories associated with implementing EHR systems, namely: infrastructure (e.g., hardware and software), personnel (e.g., project management and training teams), estates or facilities (e.g., furniture and fittings), and other (e.g., consumables and training materials). Many factors were felt to impact on these costs, with different hospitals choosing varying amounts and types of infrastructure. This infrastructure was dependent on the stage of hardware maturity within the hospital; the requirements of the software application being implemented; the products currently available on the market; the budget (if predetermined); and the physical requirements of the wards or office rooms. The amount of resource spent on training clinicians and administrative staff to use the new EHR system depended on the number of users at each site; the training methods employed; the decision to backfill staff; and the level of support provided to clinical users.

CONCLUSIONS: We found that organizations faced hard compromises relating to cost, e.g., the infrastructure implemented may not satisfy the demands of ward staff at peak times, and should therefore consider devoting specific attention to these areas in the planning phase. With cost considered one of the most significant barriers to EHR adoption, it is important for hospitals and governments to be clear from the outset as to the categories of costs involved and the factors that may impact on these costs. THE FREQUENCY OF PHLEBOTOMY AND THE INCIDENCE OF HOSPITAL-ACQUIRED ANEMIA AND WORSENING ANEMIA DURING HOSPITALIZATION Daniel A. Kim; Somali Palchaudhuri; Anthony Accurso. Johns Hopkins Bayview Medical Center, Baltimore, MD. (*Tracking ID #1931990*)

BACKGROUND: Hospital-acquired anemia (HAA) is associated with worse health status, higher hospitalization rates, increased length of stay, need for blood transfusions, greater medical costs, lower quality of life, and higher mortality. Amount and frequency of phlebotomy has been shown to be associated with HAA. Therefore, there has been a strong focus on HAA as it can potentially be prevented. HAA is defined as patients who present without anemia, and subsequently developing anemia by hospital discharge. Studies in patients who present with anemia have not been studied. It is hypothesized that if phlebotomy can cause HAA, then it should also affect patients who present to the hospital with anemia, which is a significant portion of hospitalized patients according to our prior awareness study. This study was conducted to find the incidence of worsening anemia, and to assess if it associated with phlebotomy as HAA has been shown in the past.

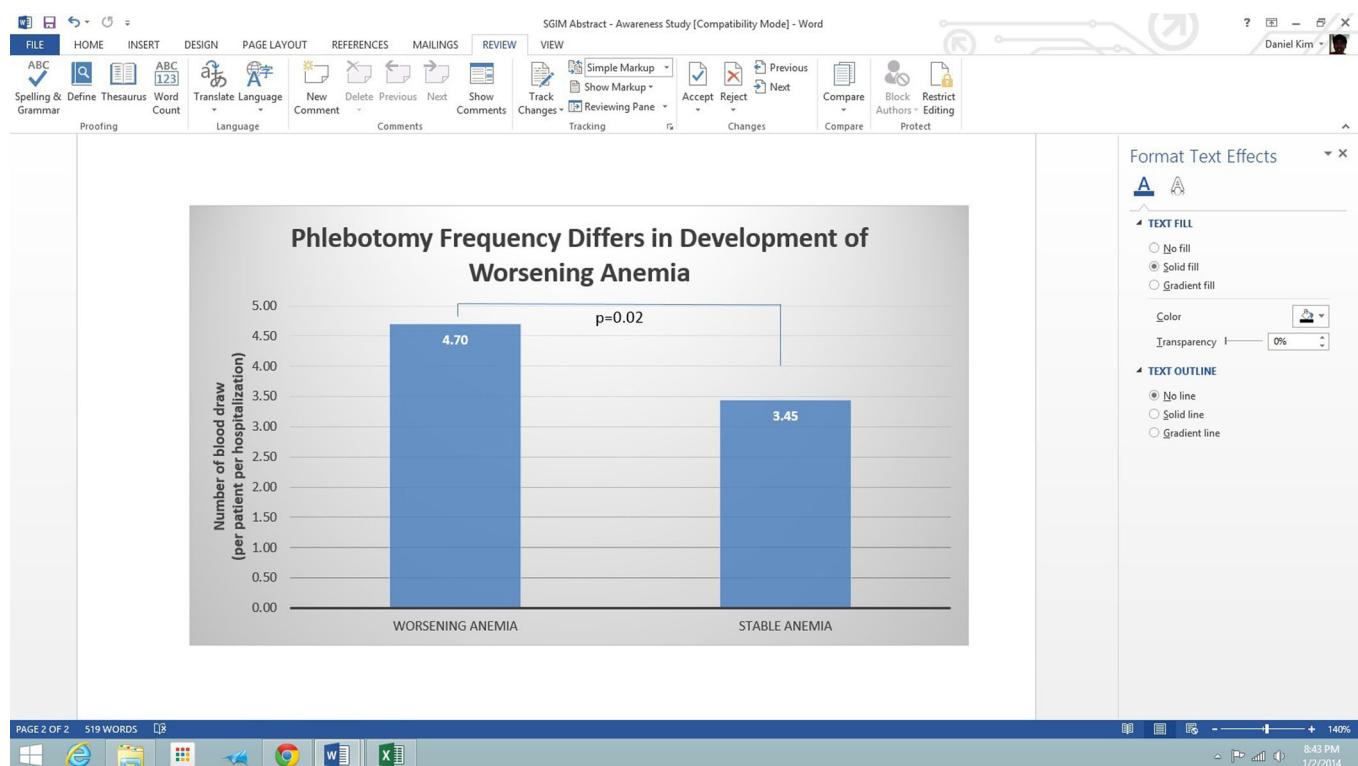

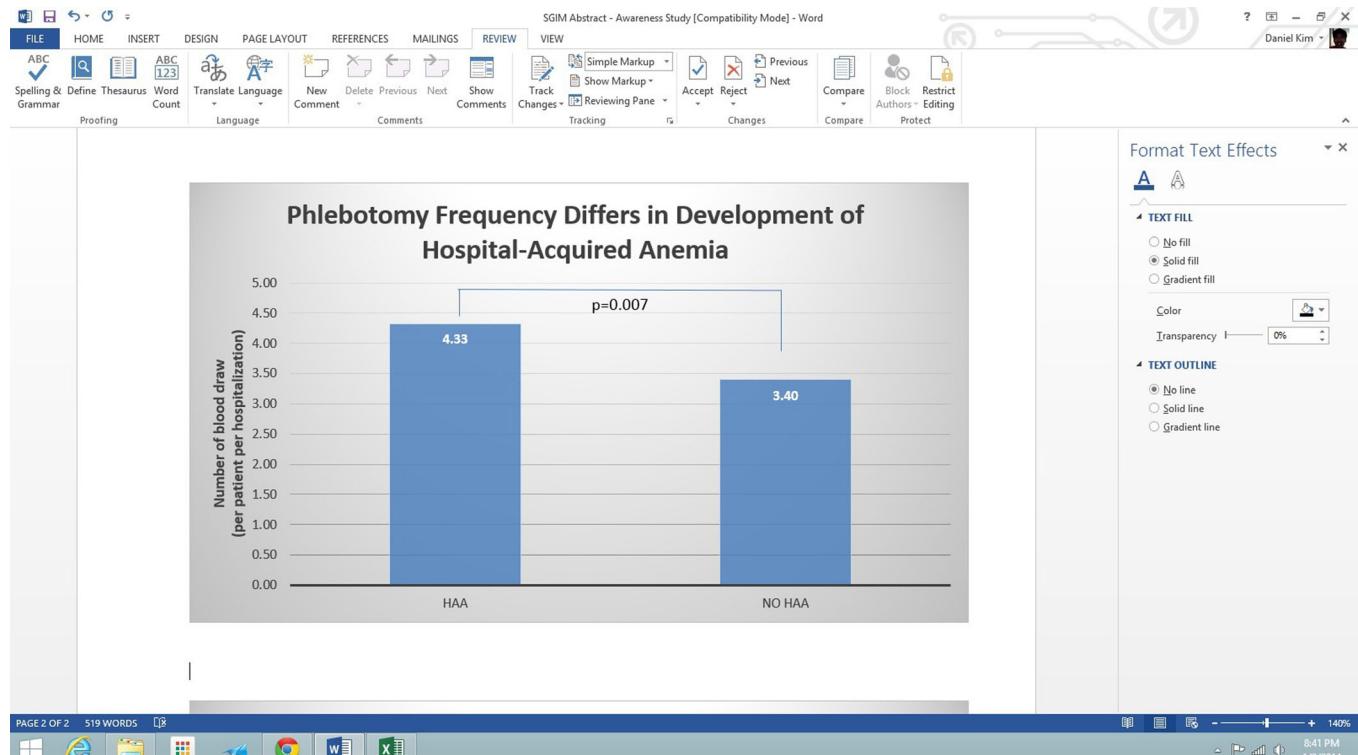

METHODS: A retrospective study of 762 adult hospitalizations in March of 2013 in a single academic medical center was conducted. Demographics, hospital information (location, length of stay, transfusion requirements), and laboratory data, including daily hematocrit levels, hemoccult (fecal occult blood) results if obtained, initial and discharge creatinine, were analyzed using administrative data. Patients with positive hemoccults, acute kidney injury (indicating hypovolemia and possible hemoconcentration), and who received blood transfusions were excluded from the study. HAA was defined as absence of anemia on admission, but development of anemia at discharge, and further categorized as severe (Hct $\leq 27.0\%$), moderate (Hct 27.1 to 33.0 %), or mild (Hct 33.0 to 36.0 %). Worsening anemia was defined by a transition to a higher severity category of anemia, ie mild to moderate, or moderate to severe anemia by discharge.

RESULTS: In patients who presented with normal Hct, there was a 31.4 % and 12.3 % incidence of overall HAA and mod-severe HAA, respectively. For HAA, there was a statistically significant difference between subjects who developed HAA and those who did not develop HAA for initial hematocrit (38.0 vs 40.7, $p<0.0001$), hospital length of stay (4.05 vs 3.34, $p=0.03$), and total phlebotomy frequency (4.33 vs 3.40, $p=0.007$). In patients presenting with mild to moderate anemia, almost half (49.0 %) had worsening anemia from admission to discharge. A statistically significant difference in the total number of blood draws was seen between those that developed worsening anemia and those that did not (4.70 vs 3.45 blood tests per hospitalization, $p=0.02$). Unlike HAA, patients with worsening anemia did not have significant difference in creatinine, length of stay, initial hematocrit than those that did not have worsening anemia.

CONCLUSIONS: Our findings suggest that hospital-acquired anemia as well as patients whose anemia worsens during hospitalization occurs frequently in our hospital. As seen in prior studies, HAA is associated with phlebotomy

frequency and hospital length of stay. Similar to HAA, worsening anemia during hospitalization is significantly associated with higher frequency of phlebotomy. Although HAA has been well studied, to our knowledge, worsening anemia during hospitalization has not been examined. Further studies are needed to determine the clinical significance of worsening anemia; however,

it is likely to be significant considering that HAA has been shown to be associated with worse health outcomes, increased hospitalization, and higher mortality to name a few. This study also implicates the possibility of targeting phlebotomy frequency to reduce the incidence of worsening anemia in the hospital, and not only for HAA.

THE HUNT FOR DIABETES: CHARACTERISTICS AND RISK FACTORS ASSOCIATED WITH UNDIAGNOSED DIABETES AND PREDIABETES IN NHANES Michael E. Bowen^{1,2}; Lei Xuan²; Ethan Halm^{1,2}. ¹UT Southwestern Medical Center, Dallas, TX; ²UT Southwestern Medical Center, Dallas, TX. (Tracking ID #1937085)

BACKGROUND: Over 7 million people with diabetes (DM) and 73 million people with prediabetes (preDM) in the US are undiagnosed. Although characteristics of individuals with diagnosed DM and preDM are well described, those with undiagnosed disease are less well characterized. Understanding risk factors and characteristics of individuals with undiagnosed DM and preDM are essential to successful case-identification strategies.

METHODS: Non-pregnant adults without self-reported DM and preDM in the 2005–2009 NHANES survey were analyzed. Using A1C and fasting glucose, participants were classified as normal (A1C<5.7 % and fasting glucose<126 mg/dL), undiagnosed preDM (A1C 5.7–6.5 % or fasting glucose 100–125 mg/dL), or undiagnosed DM (A1C≥6.5 % or fasting glucose≥126 mg/dL). Patient characteristics and risk factors were obtained from interview and exam survey components. Associations between risk factors and undiagnosed preDM and DM were examined using logistic regression with the normal glucose group as a reference. We present results weighted to national estimates.

RESULTS: Of the 13,792 participants without diagnosed DM, 65 % had normal glucose, 32 % had undiagnosed preDM, and 3 % had undiagnosed DM. Forty-four percent of individuals with undiagnosed DM and 54 % of those with undiagnosed preDM reported not being screened for DM in the past 3 years—potential screening or diagnostic failures. In univariate analyses, undiagnosed DM and preDM were associated with: older age, BMI≥25, non-white race, hypertension, hyperlipidemia, and a family history of DM ($p<0.001$; Table 1). Having less than a high school education (DM OR=2.0, $p<0.001$; preDM OR=1.6, $p<0.001$) and Medicare insurance (DM OR=5.3, $p<0.05$; preDM OR=2.3, $p<0.001$) were also associated with undiagnosed disease. Those with undiagnosed disease were more likely to have ≥2 MD visits in the past year (undiagnosed DM OR=1.4, $p=0.02$; undiagnosed preDM OR 1.3, $p<0.001$). Individuals satisfying ADA and USPSTF screening criteria were more likely to have undiagnosed DM (ADA OR=15.6; USPSTF OR=4.8, $P<0.001$ for both) and preDM (ADA OR=5.2; USPSTF OR=2.5, $p<0.001$ for both) than those with normal glucose. The strongest single predictor of undiagnosed DM was a single random glucose≥100 mg/dL (OR=74.1, $p<0.001$). A single random glucose≥100 mg/dL (OR=4.5, $p<0.001$) was a better predictor of undiagnosed preDM than USPSTF (OR=2.5, $p<0.001$) but inferior to ADA guidelines (OR=5.2, $p<0.001$). After multivariate adjustment for age, gender, race, BMI, hypertension, hyperlipidemia, cardiovascular disease, and family history of DM, random glucose≥100 mg/dL remained a robust predictor of undiagnosed DM (OR 51.3, $p<0.001$).

CONCLUSIONS: Risk factors included in ADA and USPSTF guidelines are associated with undiagnosed DM and preDM. However, a single RBG≥100 mg/dL is the best single predictor of undiagnosed DM and superior to either national guideline. Those with undiagnosed disease are routinely engaged with the healthcare system and greater attention to abnormal RBG values may improve identification of undiagnosed DM and preDM.

Table 1. Patient Characteristics Associated with Undiagnosed Prediabetes and Diabetes

Characteristic	Undiagnosed Prediabetes	Undiagnosed Diabetes
Age ≥45	3.5 (3.1, 3.9)	6.8 (5.3, 8.8)
BMI≥25 kg/m ² , (SE)	2.3 (2.1, 2.6)	6.5 (4.5, 9.4)
Non-white Race, % (SE)	1.2 (1.1, 1.4)	1.5 (1.2, 2.0)
Family History Diabetes	1.4 (1.2, 1.5)	1.9 (1.5, 2.4)
Hypertension	2.5 (2.2, 2.7)	4.8 (3.8, 6.0)
Hyperlipidemia	2.0 (1.8, 2.2)	2.4 (2.0, 3.0)
Cardiovascular Disease	2.5 (2.1, 3.1)	4.7 (3.5, 6.3)
ADA guidelines	5.2 (4.5, 5.9)	15.6 (8.1, 29.8)
USPSTF Guidelines	2.5 (2.2, 2.7)	4.8 (3.8, 6.0)
Random glucose ≥100 mg/dL	4.5 (3.9, 5.1)	74.1 (53.1, 103.4)

Data presented as weighted Odds Ratio (95 % CI); $p<0.001$ for all values BMI: Body mass index ADA: American Diabetes Association USPSTF: US Preventative Services Task Force

THE IMPACT OF A COMMUNITY HEALTH CENTER PATIENT NAVIGATION PROGRAM ON ABNORMAL MAMMOGRAPHY FOLLOW-UP Sanja Percac-Lima^{1,2}; Jeffrey M. Ashburner²; Sorbarikor Piawah³; Anne Marie McCarthy^{1,2}; Steven J. Atlas². ¹Massachusetts General Hospital, Chelsea, MA; ²Massachusetts General Hospital, Boston, MA; ³Harvard Medical School, Boston, MA. (Tracking ID #1939688)

BACKGROUND: Despite advances in screening, diagnosis and treatment of breast cancer, patients continue to present with advanced disease. This is especially true for racial and ethnic minorities, underinsured, low income, and limited English proficiency patients. Patient navigation has been shown to improve screening and follow-up after abnormal results, particularly among disadvantaged women. We evaluated the impact of a patient navigation (PN) program as part of usual care at a community health center (CHC) on follow-up of abnormal mammograms.

METHODS: At a CHC serving predominately disadvantaged patients, all women with an abnormal mammogram were referred to PN to help them obtain appropriate follow-up care. In this retrospective study, we compared women from the CHC who had an abnormal screening mammogram (Breast Imaging-Reporting and Data System (BI-RADS 0,3,4,5) referred for PN between 2007 and 2010 with disadvantaged women (non-White, non-English speakers, or with Medicaid/Free care or no insurance) who had an abnormal screening mammogram during the same time period and received care in other practices within the same primary care network that did not have PN. The primary outcome was time to follow-up and the proportion of women who received appropriate follow-up between the two groups. Appropriate follow-up was defined: BI-RADS 0: follow-up within 3-months, BI-RADS 3: follow-up within 9-months and BI-RADS 4/5: biopsy within 3-months. Women with BI-RADS 0 who received a follow-up mammogram with BI-RADS 3, 4, or 5 were reclassified into the higher BI-RADS category. Patient characteristics between groups were compared using t-tests or chi-squared tests. We used logistic regression and Cox proportional hazards modeling to compare the receipt of and time to appropriate follow-up care between groups adjusting for patient age, race, primary language, number of clinic visits, and whether or not the patient was linked with a specific primary care physician (PCP).

RESULTS: Over the four-year period, there were 146 women with total 168 abnormal mammograms in the CHC with PN and 223 women with 239 abnormal mammograms in the practices without PN. Women from the CHC with PN were more likely to be Latina, linked to a specific PCP, less likely to speak English, and had more clinic visits over the prior 3-years. There were no significant differences by age or insurance status between groups. In the CHC with PN, 151 of 168 (89.9 %) abnormal mammograms received appropriate and timely follow-up compared to 182 of 239 (76.2 %) in the other practices (adjusted $p=0.006$). Most women with BI-RADS 0 received appropriate follow-up in both groups (90.0 % vs. 86.7 % in control, $p=0.55$). In women with BI-RADS 3, more navigated women (85.4 %) received appropriate follow up than women from practices without PN (52.3 %, $p=0.003$). Among women with BI-RADS 4/5, 92.9 % of women from the CHC with PN received appropriate follow-up compared with 82.0 % of women in control practices ($p=0.19$). Time to follow-up was similar between groups following BI-RADS 0 (adjusted hazard ratio (HR), 95 % CI: 1.16 [0.88–1.53]). Women from the CHC with PN received follow-up care sooner than patients from other practices following BI-RADS 3 (HR [95 % CI]: 2.34 [1.37–4.02]) and BI-RADS 4/5 (HR [95 % CI]: 1.46 [0.93–2.30]).

CONCLUSIONS: Disadvantaged women receiving care in a CHC with PN were more likely to receive appropriate follow-up after an abnormal mammogram than disadvantaged women seen in practices without PN. Expanding PN to include all disadvantaged women within primary care networks should be further evaluated as a way to improve equity in cancer care.

THE IMPACT OF A DIABETES-SPECIFIC HEALTH PLAN ON ED AND INPATIENT HOSPITAL USE Tannaz Moin^{1,2}; Neil Steers²; Susan Ettner²; O. Kenrik Duru²; Norman Turk²; Charles Chan³; Robert H. Luchs³; Anya Kirvan³; Sam Ho³; Carol Mangione². ¹VA Greater Los Angeles Healthcare System and HSR&D Center for Healthcare Innovation, Los Angeles, CA; ²David Geffen School of Medicine at UCLA, Los Angeles, CA; ³UnitedHealth Group, Minneapolis, MN. (Tracking ID #1938946)

BACKGROUND: In the U.S., diabetes-related care accounts for approximately 1 in every 5 health care dollars. Timely and appropriate ambulatory care can help prevent diabetes-related complications that often lead to costly ED visits and/or hospital admissions. The Diabetes Health Plan (DHP) is the first disease-specific health plan for patients with diabetes and pre-diabetes. The DHP provides pharmacy and office visit financial incentives to enhance access to routine care, as well as additional resources for chronic disease management. This study examined changes in annual adjusted rates of ED and inpatient hospital utilization associated with employers' purchase of the DHP, using employers who did not purchase the DHP as concurrent control groups.

METHODS: We conducted a retrospective, employer-level, intent-to-treat analysis, which included aggregate insurance claim and laboratory data from all employees and dependents with diabetes and pre-diabetes between 19 and 63 years of age, whether or not they were enrolled in the DHP. The 3-year consecutive study window included an initial 12 months of pre-period data (to conduct a baseline assessment and define the study sample) and 24 months of follow-up data (at 1 and 2 years post-DHP implementation). Inverse propensity score weighting was used to adjust for differences in employer level variables including mean age, education level, income, number of chronic medical conditions, proportion of female employees, proportion of employees from different demographic groups, proportion of employees with diabetes and pre-diabetes, and baseline rates of ED and inpatient hospital use between the DHP and control employers. Estimates were used to calculate the average treatment effect on the treated (ATET), or the difference between predicted rate of ED and inpatient hospital use among employer groups offering the DHP and their predicted rates if they had not offered the DHP.

RESULTS: Our results included 3 years of data from 9 employer groups who offered the DHP and 185 control employer groups who did not offer the DHP. Unadjusted rates of ED use were similar at baseline (DHP 7.64 %, control 8.60 %) but ED use decreased at 2 years in DHP groups (DHP 4.50 %, control 9.43 %). Our ATET analysis showed no evidence of significant reduction in ED use at 1 year post DHP but did show a 3.8 percentage point predicted reduction ($p=0.015$) in the mean rates of ED use at 2 years post-DHP implementation, representing a 46 % decrease relative to the predicted baseline rate of 8.3 % ED use. No evidence was found of any significant association with predicted inpatient hospital use at 1 and 2 years post-DHP implementation.

CONCLUSIONS: We found that employers who offered the DHP had a 46 % reduction in the adjusted mean rates of ED use at 2 years post-implementation compared to the predicted mean rates of ED use had they not offered the DHP. Longer-term studies may be needed to observe any significant impact on inpatient hospital use. These findings suggest that health insurance benefit designs that decrease out of pocket costs for medications and preventive care can play an important role in decreasing the cost for more resource intensive services such as ED use for persons with diabetes and pre-diabetes.

THE IMPACT OF A PATIENT-CENTERED MEDICAL HOME ON VETERANS WITH DIABETES MELLITUS Sivasubramanium Bhavani^{1,2}; Andrew Spiegelman²; Utpal Ghosh^{1,2}; Madhuri M. Vasudevan^{1,2}. ¹Baylor College of Medicine, Houston, TX; ²Michael E. DeBakey Veterans Affairs Medical Center, Houston, TX. (Tracking ID #1938167)

BACKGROUND: Over five million veterans receive primary care from the Veteran Health Administration (VHA), making it the nation's largest integrated health care delivery system. The VHA has launched the Patient Aligned Care Team (PACT) initiative to provide a patient-centered medical home for this sizable population. This paper examines the effect of the PACT in the management of diabetes mellitus in veterans receiving care at the Houston Michael E. DeBakey VA Medical Center (MEDVAMC).

METHODS: All subjects with diabetes mellitus enrolled in primary care clinics at the MEDVAMC were included in this retrospective pretest/posttest design study. Data was collected over a 2 year period consisting of a 1 year pre-PACT period and a 1 year post-PACT period. For each subject, the most recent HbA1c, LDL-C, blood pressure, and BMI were collected from the pre-PACT and post-PACT period. If any of these values were absent, the subject was excluded from the study. A paired student's t-test was used to compare the subjects' mean HbA1c, LDL-C, blood pressure, and BMI in the pre-PACT and post-PACT periods, with each subject serving as his/her own control. Sub-group analysis was performed with subjects divided into the following groups based on the subjects' pre-PACT HbA1c: < 7 %, 7.0–9.0 %, and > 9 %. In addition to the pretest/posttest design, an interrupted time series design was used: all available HbA1cs in the pre-PACT and post-PACT periods were collected and grouped together by month relative to PACT implementation. A linear regression trend line was used to plot the trend of average HbA1c in the pre-PACT and post-PACT periods.

RESULTS: 7,105 subjects in 23 primary clinic clinics were identified. The mean HbA1c was 7.6 % in the pre-PACT period and 7.5 % in the post-PACT period ($p<0.001$). The mean LDL-C was 87.6 in the pre-PACT period and 84.4 in the post-PACT period ($p<0.001$). The mean blood pressure in the pre-PACT and post-PACT period was 130/73 ($p=0.398$ for systolic, $p=0.124$ for diastolic). The mean BMI in the pre-PACT and post-PACT period was 32.5 ($p=0.839$). The linear regression trend line of the pre-PACT HbA1c revealed an average increase of 0.01 % every month ($p=0.009$). The linear regression trend line of the post-PACT HbA1c revealed an average

decrease of 0.01 % every month ($p=0.023$). For patients designated to the pre-PACT HbA1c >9 % group, the mean HbA1c was 10.6 % in the pre-PACT period and 9.1 % in the post-PACT period ($p<0.001$).

CONCLUSIONS: The PACT focuses on employing a team-based approach to providing care, improving access to care, providing coordinated care, and forming partnerships with veterans. In the first year of PACT implementation, there has been a favorable change in HbA1c and LDL-C in the veteran population. This study confirms earlier studies demonstrating that a PCMH provides a viable system for management of chronic conditions; furthermore, this study demonstrates the viability of a medical home in the nation's largest health care delivery system.

THE IMPACT OF AN ACTIVE PERSONAL HEALTH RECORD IN PATIENTS WITH HIGH CARDIOVASCULAR RISK: A PRAGMATIC RANDOMIZED CONTROLLED TRIAL Rachel Hess¹; Sunday Clark²; Gary Fischer¹; Melissa Weimer¹; Sarah M. Sullivan¹; Mark S. Roberts¹. ¹University of Pittsburgh, Pittsburgh, PA; ²Weill Cornell Medical College, New York City, PA. (Tracking ID #1940097)

BACKGROUND: Chronic diseases that contribute to the development of cardiovascular disease are common. Efforts to improve disease management by increasing rates of guideline-recommended care delivery have focused on clinician-centered solutions and modifying systems of care. Personal health records (PHRs) provide patients with a secure view into their electronic health records (EHRs). We examined the impact of an active PHR, compared to a standard PHR, on patients' receipt of recommended care related to cardiovascular risk and 10-year cardiovascular risk.

METHODS: We recruited participants from 73 Western Pennsylvania primary care practices between June 2010 and September 2011 to participate in this pragmatic randomized controlled trial. Individuals were eligible to participate if they had (1) coronary artery disease, (2) congestive heart failure, (3) diabetes mellitus, or (4) hypertension or hyperlipidemia and were taking a medication that required routine laboratory monitoring. In addition individuals had to be willing to use the PHR. Participants in the intervention group received an active PHR that was designed in conjunction with standard PHR users. It allowed participants to view Health Maintenance topics, as in the standard PHR, and also included active reminders that notified participants when they had prevention gaps. The reminders included all services due within the next 3 months and were delivered in cycles of up to three weekly messages, with the final message accompanied by a post letter. Participants in the control group received the standard PHR. Participants completed questionnaires at baseline, 6-, and 12-months. Outcome data were abstracted from the EHR. Practices were ranked based on percent of patients receiving recommended care related to cardiovascular risk. We used Chi-square and Fischer's exact tests, as appropriate, to compare 1-year change in receipt of recommended care (low-density lipoprotein, creatinine, A1C, and potassium testing) and t-tests to compare change in 10-year cardiovascular risk (based on Framingham risk score) from baseline in the active versus standard PHR. In secondary analyses, we examined the outcomes based on the quartile rank of the participant's primary care practice for delivery of recommended care.

RESULTS: Of the 1,169 enrolled participants, 1,112 (95 %) had complete EHR data and are included in these analyses. Participants were 58.3 years old, 47 % were male, 15 % were non-white race, 38 % had diabetes, and 9 % were current smokers. At baseline 74 % of participants received A1C, 81 % low-density lipoprotein, 87 % creatinine, and 88 % potassium testing. Baseline 10-year cardiovascular risk was 11 %. At 1-year, we found no difference between the active and standard PHR groups in receipt of recommended care or 10-year cardiovascular risk. In the practices in the lowest quartile for delivery of recommended care, participants in the active PHR arm had higher rates of receipt of low-density lipoprotein (57 % vs. 43 %, $p=0.01$), creatinine (56 % vs. 44 %, $p=0.02$), and A1C (61 % vs. 39 %, $p=0.047$) testing versus standard PHR. There was no difference in potassium testing.

CONCLUSIONS: In this 1-year study of an active versus passive PHR, we found no difference in the receipt of recommended care or change in 10-year cardiovascular risk overall. While we estimated that 60 % of patients would already be receiving recommended care at baseline, we found that over 80 % received recommended care. Amongst participants seen in the practices in the lowest quartile for delivery of recommended care, we found an improvement in three of four recommended tests. Future work should explore the potential of this low-intensity intervention to improve care for patients in lower-performing practice settings.

THE IMPACT OF JOB BURNOUT ON MEASURES OF PROFESSIONALISM IN FIRST-YEAR INTERNAL MEDICINE RESIDENTS AT A LARGE URBAN ACADEMIC MEDICAL CENTER Jason Kwah; Robert Fallar; Jennifer P. Weintraub; Jonathan Ripp. Mount Sinai School of Medicine, New York, NY. (*Tracking ID #1937527*)

BACKGROUND: Internal Medicine (IM) residents commonly develop job burnout, which may lead to self-perceived sub-optimal patient care, depression, needle stick injuries and motor vehicle accidents. It remains uncertain what impact burnout has on professional behavior in this population. We hypothesize that first-year IM residents with burnout are more likely to demonstrate decreased levels of professionalism as compared with their burnout-free counterparts.

METHODS: We administered surveys to first-year IM residents at the Icahn School of Medicine at Mount Sinai twice between June 2011 and July 2012. Our survey, which has been previously reported, measured job burnout, sleepiness and other characteristics. Burnout was measured using the Maslach Burnout Inventory and defined by a high score on either the depersonalization or emotional exhaustion domain, in keeping with the most widely used convention. We subsequently gathered data on the following 3 measures of professional behavior for the same residents during the same time period: 1) Percentage of inpatient discharge summaries completed within 48 h of patient discharge, 2) Percentage of outpatient clinic charts completed within 3 days of patient encounter, and 3) Average time to review of outpatient test results ordered during patient encounters, specifically laboratory and imaging reports. The data were analyzed using SAS statistical software to identify relationships between job burnout and these measures of professionalism.

RESULTS: Of 54 eligible first-year IM residents, 53 (98 %) completed the initial survey and 32 (59 %) completed the year-end survey. Nineteen (36 %) of the 53 residents who completed the survey prior to the start of residency met criteria for job burnout. When comparing burn out residents at the start of training with their burnout-free colleagues, there were no significant differences in timely discharge summary completion (84.5 % vs. 83.5 %; $P=0.64$), timely outpatient clinic chart completion (91.4 % v. 96.1 %; $P=0.11$), and average time to review of test results. (53.9 min. vs. 393.4 min; $P=0.23$). Of the 32 residents who completed the year-end surveys, 24 (75 %) met criteria for burnout. When comparing burnt out residents with their burnout-free colleagues at year end, there were no significant differences in timely discharge summary completion (84.2 % vs. 84.1 %; $P=0.98$), timely outpatient clinic chart completion (93.6 % vs. 93.7 %; $P>0.99$), and average time to review of test results. (72.3 min vs. 26.89 min; $P=0.28$).

CONCLUSIONS: Our study found that job burnout did not correlate with certain measures of professional behavior in a single group of first-year IM residents. Furthermore, residents maintained high levels of professionalism, by our measurement, despite burnout being quite common in their cohort. These findings could be explained by a number of reasons, including the possibility that burnout has no impact on professional behavior or that the measures we chose did not adequately assess the impact of burnout on professionalism. Given that interpersonal relations are central to the professional role of the physician and depersonalization is a domain of burnout, future study should perhaps be directed at measuring the influence of burnout on other aspects of professional behavior.

THE IMPACT OF JOB BURNOUT ON MEDICATION PRESCRIPTION ERRORS IN FIRST-YEAR INTERNAL MEDICINE RESIDENTS Jennifer P. Weintraub; Robert Fallar; Jason Kwah; Jonathan Ripp. Mount Sinai School of Medicine, New York, NY. (*Tracking ID #1937580*)

BACKGROUND: Job Burnout has been increasingly recognized as common among internal medicine (IM) residents. Several studies have found that residents with burnout are more likely to self-report suboptimal patient care than those who are burnout free. Few studies have objectively measured the correlation between resident burnout and medical errors. We hypothesize that residents with burnout are more likely to commit medication prescription errors than their burnout-free counterparts.

METHODS: We administered a survey containing the Maslach Burnout Inventory to first-year IM residents at the Icahn School of Medicine at Mount Sinai twice between June 2011 and June 2012. Burnout was defined by a high score on either the depersonalization or emotional exhaustion domain, in keeping with the most widely used convention. Subsequently, data on all medication orders placed by these residents during the same 1 year period were collected. Based on pharmacy annotations, prescriber orders with the potential to cause adverse drug events (e.g. drug interactions, incorrect dosing) were identified and measured as a rate of errors per 100 prescriptions. Individual burnout scores and prescription error rates were

linked using anonymous identifiers and analyzed for correlations using SAS statistical software.

RESULTS: Of the 54 eligible first-year residents, 53 (98 %) completed an initial survey and 32 (59 %) completed a follow-up survey. Burnout prevalence was 36 % (19/53) at the beginning of intern year and 75 % (24/32) at year's end. Burnt-out residents had a significantly lower rate of pharmacy interventions compared with their burnout-free counterparts in both the initial survey (0.558/100 vs. 0.752/100; $p=0.005$) and the year-end survey. (0.553/100 vs. 0.780/100; $p=0.007$)

CONCLUSIONS: Burnt-out residents committed fewer prescription errors when compared with their burnout-free colleagues. This finding was contrary to our initial hypothesis and inconsistent with previously published findings based on self-report. Given the low error rate and the uncertain clinical significance of a correlation between burnout and decreased prescriber errors, further research is necessary to evaluate the link between job burnout and patient care in IM residents.

THE IMPACT OF PATIENT-CENTERED MEDICAL HOME TRANSFORMATION WITHIN VETERANS HEALTH ADMINISTRATION ON PATIENT EXPERIENCE OF CARE Ashok Reddy^{1,4}; Anne Canamucio²; Rachel M. Werner^{2,3}. ¹University of Pennsylvania, Philadelphia, PA; ²VISN 4 Center for Evaluation of PACT, Philadelphia, PA; ³Leonard Davis Institute of Health Economics, University of Pennsylvania, Philadelphia, PA; ⁴Robert Wood Johnson Clinical Scholar Program, University of Pennsylvania, Philadelphia, PA. (*Tracking ID #1938552*)

BACKGROUND: The patient-centered medical home (PCMH) is an innovative primary care health delivery model that places an emphasis on delivering 'patient-centered' healthcare. However, there is little known regarding whether medical home transformation improves patients' experience of care. In 2010, the Veterans Health Administration (VHA) began implementing its own medical home model, termed Patient Aligned Care Teams (PACT), across all primary care clinics nationwide. Our study takes place in one mid-Atlantic region of the Veterans Health Administration (VISN 4), which includes 56 primary care sites providing care for over 300,000 veterans. We evaluate the impact of adoption of the medical home model on patient experience of care.

METHODS: Patients were selected from the VHA quality improvement assessment program, the Survey of Healthcare Experiences of Patients (SHEP). For our study cohort, we identify patient survey respondents between July 2010 and October 2012. Our primary outcomes include 5 composite measures of patient care experience: how well doctors/nurses communicate, rating of personal doctor/nurse, getting needed care, overall rating of VA healthcare, and getting care quickly. We examine the effect of PACT implementation on these outcomes using two sources of variation—the timing and the effectiveness of PACT implementation across study sites. To do so, we first obtained the date when each primary care provider (PCP) became a PACT provider. Second, based on qualitative site-level interviews, we developed two types of site-level measures of PACT effectiveness: 1) nine indicators for structural changes supporting the PACT model and 2) a scale variable measuring the quality of PACT implementation. For our analysis we use a repeated cross-sectional design to evaluate the impact of the medical home transformation on patient experience of care. We conduct patient-level analyses, with patients clustered within PCPs and sites of care to test whether changes in health care delivery in the VHA under the PACT transformation led to changes in patient experience of care. Our linear probability models are adjusted for age, sex, race, income, and risk-based DCG scores and include PCP-level fixed effects.

RESULTS: Our analyses include SHEP responses from 28,041 patients who were associated with 568 physicians. The median age of respondents was 68 and most were male (96 %) who self-identified as white (91 %). A majority of respondents had a positive experience of care in 3 domains: how well doctor/nurse communicate (59 %), rating of personal doctor/nurse (77 %), and overall rating of the VHA (65 %). Over the study period the percentage of PCPs who were part of the PACT increased from 8.2 % in the first time period to 81.1 % in the last time period. Similarly, we observe an increase the implementation of PACT structural changes and the quality of that implementation. For example, the use of high-risk registries increased from 6.9 % in the first time period to 64.2 % in the last. In our primary analysis, we found no association between medical home transformation and patient experience of care using any of the three measures of PACT implementation. For example, patients assigned to a PACT provider had a 0.51 % ($p=0.66$) higher response in how well they communicate with their provider compared to patients not assigned to a PACT provider and to patients in the pre-PACT period.

CONCLUSIONS: While the medical home model is increasingly adopted, in part to improve patient experience of care, we did not see an improvement in patient care experience in the VHA.

THE IMPORTANCE OF TRAINING IN THE IMPLEMENTATION OF AN OUTPATIENT DEPRESSION SCREENING AND TREATMENT PROTOCOL

BACKGROUND: Patients in primary care settings have a high prevalence of depression and these patients often have worse outcomes for chronic medical conditions. Systematic approaches to the identification and management of depression, such as the stepped care approach, improve the management of depression within the primary care setting. These team-based models of care have gained broad acceptance as the preferred approach to caring for patients with chronic disease. However, implementing these new approaches to care in "real world" settings presents both new opportunities and challenges.

METHODS: From 2012 to 2013 we implemented the Depression Protocol at two academic internal medicine primary care clinics associated with one academic medical center. Providers were offered a one-hour training in the rationale for the protocol and in the care processes associated with the protocol. The Depression Protocol utilizes a stepped-care treatment algorithm based on Patient Health Questionnaire (PHQ) 9 scores. The primary protocol procedures are: 1) The Medical Assistant (MA) administers the PHQ-2 on all patients at new patient or annual visits. 2) The MA gives a paper PHQ-9 to patients with a positive PHQ-2. 3) The provider documents the PHQ-9 into the Electronic Medical Record (EMR). 4) The provider treats the patient based on the PHQ-9 score and their clinical judgment. 5) Patients with positive PHQ-9 scores are reassessed in person in 1–3 months depending on score and treatment strategy. 6) The PHQ-9 is administered at the follow-up visit. 7) When a psychotropic medication is started or changed, the provider initiates a 1–2 week follow-up call by a member of the provider's team (MA or nurse). We performed a retrospective analysis of provider documentation of protocol processes: 1) documentation of PHQ-9 at visits for patients with positive PHQ-2 s and 2) PHQ-9 monitoring at subsequent visits for patients with positive PHQ-9 s. We utilized both descriptive and logistic regression analysis to assess the association between in-person training attendance and provider performance of the protocol. We employed a generalized estimating equation to control for correlation between documentation within the same provider. We also administered a survey to assess provider comfort with protocol procedures (Procedures), provider perception of impact of training on their competency in managing depression (Competency). Two scales were developed corresponding to the Procedures and Competency questions. We calculated a Cohen's d effect size for the effect of training on the outcomes.

RESULTS: Clinic 1 (C1) had 32 resident and 26 faculty providers; Clinic 2 (C2) had 21 and 18, respectively. Average documented PHQ-9 s for positive PHQ-2 s for C1 residents, C1 faculty, C2 residents, and C2 faculty was 70.6 %, 66.6 %, 48.8 % and 60.9 %, respectively; and average patients with a repeated PHQ-9 were 27.4 %, 31.4 %, 20.0 %, and 37.0 %, respectively. Logistic regression analysis (see table) showed training attendance was positively associated with documentation of PHQ-9 after a positive PHQ-2 [OR=2.4 (1.3–4.3)] and repeated documentation of a PHQ-9 after a positive PHQ-9 [OR=2.5 (1.1–5.3)]. In the provider survey, there was a moderate effect size ($d=0.4$) of training attendance on the Procedures outcome. There was no significant effect on provider Competence outcome ($d=0.04$).

CONCLUSIONS: That training was associated with increased odds of compliance with protocol procedures, and a moderate effect size for comfort with protocol procedures, points to the importance of practical training in the implementation of practice change in the primary care setting. The movement toward team-based care has been adopted on a national policy level through incentives in the Affordable Care Act for primary care practices to adopt the Patient-Centered Medical Home (PCMH) model. Healthcare administrators and researchers need to consider multifaceted approaches, which incorporate practical training, as they implement these new models of care in the primary care setting. In order to improve provider compliance with the Depression Protocol, an online training module was developed in October 2013, making training accessible to all resident and attending providers in the two clinics.

Multiple Logistic Regression for PHQ-9 documented for Positive PHQ-2 and Repeated PHQ-9 for Positive PHQ-9

Characteristic	* Adjusted OR	Confidence Interval
Documented PHQ-9 for Positive PHQ-2		
Provider (Attending)	0.8	0.5–1.5
Clinic (Lowry)	0.6	0.3–1.2
Training (Attended)	2.4	1.3–4.4
Repeated PHQ-9 for Positive PHQ-9		
Provider (Attending)	1.2	0.6–2.3
Clinic (Lowry)	1.2	0.7–2.1
Training (Attended)	2.5	1.1–5.3

*Repeated documentation by providers have been accounted for using the GEE model. All the variables (provider type, clinic type, and training attendance) were added simultaneously as covariates.
