CASE: A 47-year-old male presented with 2 months of abdominal pain, constipation, fatigue, and 20-lbs. weight loss. He described "something pushing" on his colon and the urge to defecate. He had also noted a change in his stool caliber and described straining 4–6 times daily and difficulty passing "ribbon shaped" stools. Past medical history was remarkable for migraine headaches and use of ergot-based medications 10 years prior to presentation. Physical exam, including vital signs, was normal. Labs, including CBC and renal function, were also normal. Abdominal and pelvic CT scan showed periaortic soft tissue thickening surrounding the infrarenal abdominal aorta and proximal common iliac arteries, suggestive of retroperitoneal fibrosis (RF). Peripheral blood flow cytometry did not show atypical findings. Colonoscopy and EGD were normal. Patient was started on high dose steroids (1 mg/kg), reported complete symptom resolution within days, and had marked radiographic improvement in the extent of disease. After a month, daily prednisone dose was decreased to 10 mg. After remaining symptom-free and having stable imaging for 8 months, patient presented to an outside facility with recurrent symptoms, including "flat stools." Outside CT reported aortitis. Addition of cellcept has resulted in improvement of his symptoms to date.

DISCUSSION: RF encompasses a range of diseases characterized by presence of fibro-inflammatory tissue in the retroperitoneum. Presenting signs and symptoms are non-specific and include fever, pain in abdomen/flank/back, anorexia, weight loss, renal failure, hypertension, and deep venous thrombosis. While the majority of RF cases are idiopathic, others are associated with recognized etiologies, such as malignancy, certain infections, drugs (e.g. ergotamines, hydralazine and beta blockers), abdominal aortic aneurysm, radiation therapy, surgery, or trauma. It has also been suggested that RF is mediated by the immune system. In fact, idiopathic RF may be part of a systemic fibrosing disease, such as immunoglobulin G4 (IgG4)-related disease. We believe our patient's RF is either IgG-related or associated with his previous use of Ergot compounds. Laboratory findings are also nonspecific and consist of anemia and elevated erythrocyte sedimentation rate and serum creatinine. CT and MRI are the best diagnostic modalities for RF. As illustrated by our case, classical radiographic findings include a confluent mass surrounding the infrarenal aorta and other retroperitoneal structures. Biopsy is not necessary for the diagnosis, but is appropriate if malignancy or infection is suspected, location of fibrosis is atypical, or there is inadequate response to initial treatment. Careful history and physical exam would reveal causes of secondary RF, such as malignancy or drugs. Suspected drugs should be discontinued. If appropriate, patients should undergo age-appropriate malignancy screening. Surgical treatment might be required for obstructive complications. Successful nonsurgical management of idiopathic RF with various immunosuppressive agents (e.g. corticosteroids, azathioprine) and hormonal medications (e.g. tamoxifen) have been reported. This case highlights the importance of maintaining a high index of suspicion for RF, even in patients without classical urinary symptoms. Prompt diagnosis and treatment not only provide symptom-relief, but can also preserve renal function, prevent other organ involvement, and reduce need for surgical intervention.

RIZATRIPTAN INDUCED RENAL INFARCT IN A MIDDLE AGED MALE WITH MIGRAINES Saurabh K. Bansal; Emani Vamsi. University of Illinois College of Medicine at Peoria, Peoria, IL. (*Tracking ID #1938756*)

LEARNING OBJECTIVE 1: With this case we would like to emphasize to practicing physicians to be able to recognize renal infarction as one of the potential side effects of the Rizatriptan.

LEARNING OBJECTIVE 2: With this case we would like to emphasize to practicing physicians about the vaso-occlusive and ischemic side effects of Triptan class of medications.

CASE: 44 year old male presented with 1 week history of nausea, vomiting and vague diffuse abdominal pain. He denied fever, chills, dyspnea, diarrhea and abnormal weight gain/loss. He had history of migraines and was on Topamax for preventive therapy and Rizatriptan for as needed therapy for recurrent headaches. He took approximately two tablets of rizatriptan per week for last few weeks. He denied any personal or family history of autoimmune disorder or clotting disorders. Reported smoking marijuana rarely but no cocaine. On visual appearance he appeared dehydrated. Vital signs were normal, pulse rate 92 beats/min and blood pressure of 115/72 mm of Hg. Abdomen was soft with reproducible tenderness in the left CVA region. No murmur was heard during the cardiovascular examination. CT scan with contrast of abdomen showed hyperechoic wedge shaped shadow on the upper pole of the left kidney. This was highly suggestive of a renal infarct. Hemoglobin, creatinine, electrolytes, liver function tests and urinalysis were all within normal limits. Urine drug screen was only positive for cannabinoids. ESR, CRP elevated at 33 and 6.79 respectively. Prothrombin time and PTT minimally elevated at 16.9 s and 41 s respectively. ANA, RF and ANCA, Factor V leiden, lupus anticoagulant and homocysteine tests were all negative. Protein C&S levels were slightly lower than normal levels. EKG showed sinus rhythm and 2D Echocardiogram did not show any LV thrombus. Renal Doppler ultrasound did not show any renal artery stenosis. He was managed conservatively and improved slowly in the next few days. No further complications were noted. Repeat urinalysis and creatinine were normal.

DISCUSSION: Rizatriptan/maxalt is fairly safe medication in terms of side effects. Myocardial infarction, stroke, GI ischemia or splenic infarction had been mentioned on the prescriber's sheet. Renal infarction is not mentioned anywhere in the list of side effects. Renal Infarction is a rare disorder. Most common causes of renal infarction are - Thromboemboli or in-situ thrombosis. Patients with embolic phenomenon have atrial fibrillation, cardiac thrombus, endocarditis or aortic atheroma. Patients with non-embolic occlusion have renal artery dissection, fibromuscular dysplasia or hypercoagulable state. In our patient, hypercoagulable workup was negative by lab testing and negative renal duplex study ruled out renal artery stenosis or dissection. EKG and in hospital cardiac monitoring for 72 h showed normal sinus rhythm. Transthoracic Echocardiogram was negative for any cardiac thrombus or vegetations. We believe in this healthy adult middle aged male, renal

infarct was a result of prior Rizatriptan use. Rizatriptan had been previously associated with coronary ischemia, gastrointestinal ischemia and splenic infarcts due to peripheral vasoconstrictive properties. So this is completely plausible to have vasoconstriction elsewhere resulting in ischemia, such as what happened, presumably, in a segmental branch of left renal artery in our patient. Renal infarct due to Rizatriptan had only been reported once before (see reference 1), describing two such cases1. Our patient was discharged home with advice not to use Rizatriptan again. No anticoagulation was started since we did not find any evidence of hypercoagulability or clotting disorder or this as an acute embolic/thrombotic event. References: 1) Renal infarction during the use of rizatriptan and zolmitriptan: two case reports. Fulton JA, Kahn J, Nelson LS, Hoffman RS. Clin Toxicol (Phila). 2006;44(2):177-80.

ROUX EN YAM I SO TIRED? Rachel Sandler; Catherine Jones. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1926241*)

LEARNING OBJECTIVE 1: Identify gastric bypass surgery as a risk factor for iron deficiency anemia

LEARNING OBJECTIVE 2: Recognize the nutritional deficiencies associated with gastric bypass surgery

CASE: A 43-year-old African American woman presents with complaints of fatigue and shortness of breath worsening over the past year. She also noted associated chest pressure when having long conversations and with exertion. Past medical history was notable for recurrent episodes of anemia requiring transfusion along with laparoscopic gastric bypass surgery that was converted to an open procedure over 10 years ago. Her only medication was a multivitamin. On physical exam, vital signs were normal. She had anterior rim pallor and prolonged capillary refill. She had a 2/6 systolic flow murmur and lungs were clear to auscultation. Complete blood counts showed hemoglobin of 4.4 g/dL and a mean corpuscular volume of 52.7 fL. Peripheral blood smear showed microcytes and polychromasia. Ferritin was 1.9 ng/mL. Hemoglobin electrophoresis showed no evidence of hemoglobinopathy. On chart review, 3 years ago iron studies revealed iron of 9 µg/dL, iron saturation 9 %, and total iron binding capacity 419 µg/dL. Transferrin was 322 mg/dL. Ferritin at that time was 2.9 ng/mL. During her hospital course, she was transfused 2 units of packed red blood cells with appropriate rise in her hemoglobin and significant improvement in her symptoms. She was initiated on a trial of oral iron therapy prior to discharge.

DISCUSSION: While gastric bypass surgery has become a common and effective approach to treating obesity, this surgery, particularly Roux-en-Y, is not without its long-term complications, including iron deficiency anemia. The Roux-en-Y gastric bypass works by both restricting the size of the stomach through the creation of a remnant pouch and malabsorption by shortening the small intestine. Positive effects of this procedure include significant weight loss, reduction in cholesterol and triglyceride levels, and reversal of type 2 diabetes. However, as in this patient, 6–50 % of patients develop clinically significant iron deficiency anemia after Roux-en-Y surgery secondary to disruption of iron absorption in the duodenum and proximal jejunum, which are bypassed in the procedure. As gastric bypass procedures have become a more common method for treating obesity, a growing body of evidence has shown that nutritional deficiencies are common after surgery. Iron and vitamin B12 are particularly common micronutrient deficiencies, along with the fat-soluble vitamins (A, D, E, and K) and thiamine (vitamin B1). In addition to factors directly influencing iron absorption, chronic inflammation due to obesity and changes in iron hemostasis related to decreased hepcidin can also play a concomitant role in anemia in bariatric surgery patients. In some cases, oral iron supplementation is sufficient to replete iron stores, especially at higher doses, and with reducing agents like Vitamin C. Some cases do require IV iron for resolution. Recognition of iron deficiency in the setting of bariatric surgery is essential to recognize as a complication of this common obesity treatment.

RUPTURE OF SINUS OF VALSALVA ANEURYSM: A RARE BUT IMPORTANT CAUSE OF HYPOTENSION AND RENAL FAILURE Ahmed Salman; Patrick Quinlan; Anthony Donato. Reading Health System, West Reading, PA. (*Tracking ID #1934613*)

LEARNING OBJECTIVE 1: In patients presenting with acute hemodynamic instability and new cardiac murmurs, cardiac etiology should be suspected .

LEARNING OBJECTIVE 2: A bedside transthoracic echocardiogram is an effective approach to rule out rupture of sinus of valsalva aneurysm .

CASE: Aneurysms of Sinus of Valsalvas (ASVs) are rare cardiac anomalies found at autopsy studies in 0.09 % of the population, as the result of congenital malformations, connective tissue disease (e.g. Ehler-Danlos, Marfan's), infections or thoracic trauma. While typically asymptomatic, rupture of the aneurysm will result in profound hypotension and

renal failure. Fifty-seven year old man presented to emergency department with a 5 day history of non-radiating mild precordial chest pain associated with nausea, vomiting and decreased urine output. On examination he was afebrile with a blood pressure of 70/40 and a pulse rate of 95 beats per minute. Despite receiving 4L of IV normal saline, his blood pressure continued to range between 80 and 100 systolic. Initial workup revealed elevated BUN and creatinine concentrations (190 mg/dL (Normal 5–26 mg/dL) and 17.6 mg/dL (Normal 0.5–1.5 mg/dL) respectively). On physical exam the patient was noted to have a continuous 3/6 murmur on left sternal border with a friction rub. Given the refractory hypotension and new murmur, a transthoracic echocardiogram was urgently performed, which revealed a ruptured 1.4 cm aneurysm of the sinus of valsalva. Cardiothoracic surgery was consulted, who took the patient urgently to open repair. The patient required 10 days of hemodialysis support post-operatively but recovered kidney function (Creatinine 1.65 mg/dL) by time of discharge.

DISCUSSION: Rupture of Sinus of Valsalva should be suspected in patients presenting with acute hemodynamic instability and new cardiac murmurs. Prompt diagnosis of this rare condition is required for appropriate surgical management.

SCLEROSING MESENTERITIS - A RARE DIAGNOSIS THAT MAY PRESENT AS ACUTE ON CHRONIC ABDOMINAL PAIN Anil Kumar Reddy Anumandla; Gaurav Kistangari; Omair Javed. Cleveland Clinic, Cleveland, OH. (*Tracking ID #1939221*)

LEARNING OBJECTIVE 1: Learning the differential diagnosis and treatment of Sclerosing Mesenteritis

CASE: A 66 year old man presented with complaints of worsening epigastric abdominal pain for 4 days and inability to tolerate oral intake due to severe pain. He reported similar but milder post-prandial epigastric discomfort with associated 15 lb weight loss over the past year. His past history was significant for lung cancer (treated 10 years ago) and autoimmune hemolytic anemia. At presentation his vital signs were stable. Physical examination was benign aside from severe tenderness in epigastric region. Admission labs including CBC and BMP were normal except for mild leukocytosis. Lactate was normal. Computed tomography (CT) abdomen revealed a 10 cm non-heterogeneous fatty mass extending from the root of the mesentery suggestive of SM. There was no evidence of bowel obstruction so he was treated with medical management—a trial of immunosuppressive therapy with high dose prednisone 40 mg daily and colchicine 0.6 mg BID. His pain responded dramatically over the next 2 days after which he tolerated a regular diet without any discomfort. The need for biopsy was discussed extensively but given the significant improvement with medical therapy, it was felt that percutaneous biopsy might not be useful, as it would not change management. As such, the patient was discharged on prednisone and colchicine, with the option of doing laparoscopy for definitive diagnosis in the future if he fails to respond to medical treatment. Given the association of SM with malignancy and the patient's history of lung cancer, Chest CT was done which showed no evidence of recurrence of his malignancy.

DISCUSSION: Sclerosing mesenteritis (SM) is a rare idiopathic inflammatory and fibrotic condition affecting the mesentery. The treatment of SM is tailored according to the severity of the presentation. For patients who do not have significant symptoms, a conservative approach can be followed, as the disease course is often self-limited. For symptomatic patients without obstructive symptoms, a trial of medical therapy with immunosuppressants is recommended, as illustrated in this case. If the patient has bowel obstruction or is refractory to medical therapy, then surgery is an option. SM is associated with a number of other conditions including malignancies, autoimmune disorders, or abdominal surgery/trauma. As such, a thorough diagnostic evaluation should be performed to rule out any other underlying pathology. In this case, the patient's history of lung cancer prompted a CT chest to ensure no recurrence of his cancer.

SEEING THINGS - AN UNUSUAL CAUSE OF VISUAL HALLUCINATIONS Payel J. Roy¹; Anand Kartha². ¹Boston University Medical Center, Boston, MA; ²VVA Boston Healthcare System, West Roxbury, MA. (*Tracking ID #1938747*)

LEARNING OBJECTIVE 1: Assess the differential diagnosis of visual hallucinations

CASE: Mr. L presented with a chief complaint of "I was hallucinating this morning." He is a 64 year-old man with a history of cerebrovascular accident without residual deficit, coronary artery disease, hypertension, diabetes mellitus, and pulmonary embolism status post warfarin treatment. On admission, Mr. L noted increasing confusion, memory loss, and sudden onset of visual hallucinations (VH), including speaking to a nonexistent woman and wrestling a nonexistent man. Mr. L was aware of the hallucinations throughout the event and expressed concern about them. His family history was significant for Alzheimer's dementia in his mother. Physical exam

revealed left abducens nerve palsy, right pronator drift, and slowed rapid-alternating movements. Mr. L was alert and pleasant, oriented only to name and place, had naming, abstraction, and perseverating difficulties, and 0/3 object recall at 5 min. Labs revealed a creatinine of 4.8 (baseline 1.1) and normal urinalysis. The rest of his labs, including CBC, CMP, urine toxicology, and hypercoagulable work-up, were normal. Electroencephalography was normal. MRI brain without contrast showed a subacute left hippocampal infarct.

DISCUSSION: The differential diagnosis of Mr. L's hallucinations included toxic-metabolic syndrome, possibly from acute kidney injury; seizures, given his confusion; dementia, given his family history; ophthalmologic causes, including macular degeneration, though usually only seen in patients with complete visual loss (Charles Bonnet syndrome); psychotic disorder, given the threatening nature of hallucinations; and peduncular hallucinosis, or VH arising from infarction of the midbrain. Mr. L's acute kidney injury resolved with fluids but his hallucinations persisted and his electroencephalogram was normal, making toxic-metabolic syndrome and seizures less likely. Optometry evaluated patient; he had no visual deficits and his left abducens nerve palsy was deemed related to his diabetes mellitus. Patient had no prior history of psychiatric illness and the acute onset of symptoms makes psychotic disorder and dementia less likely. Infarction of the midbrain was ruled out by MRI, thus making hippocampal infarction the most likely cause. The hippocampus is supplied by the posterior cerebral artery and its branches. Hippocampal infarction can cause memory loss and confusion. Auditory hallucinations have been seen from a lesion restricted to the hippocampus, however VH from hippocampal infarction have not been expressly seen in the literature. Instead, patients with positive spontaneous visual phenomena, including VH, have been found to have associated hippocampal lesions in the setting of agitated delirium and hemianopia. The above presentation, work-up, and subsequent Neurology consultation affirmed hippocampal infarction as the cause of Mr. L's VH. Visual hallucinations are not an uncommon presentation in general practice and can be a marker of serious medical illness. Internists should be able to assess for medical, neurologic, and psychiatric causes of these hallucinations. Key features leading to diagnosis in our patient included a thorough history of symptom acuity, risk factors for organic causes, a thorough neurologic exam, a broad differential diagnosis, and appropriate consultation and MR imaging use.

SEIZING THE DAY Rachel Sandler. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1925914*)

LEARNING OBJECTIVE 1: Identify key risk factors for intimate partner violence during history taking and physical examination

LEARNING OBJECTIVE 2: Recognize the importance of screening for intimate partner violence in patients at risk

CASE: A 55 year-old woman was admitted for new-onset seizures. She was noted to have nausea, vomiting, and blurry vision associated with a posterior occipital headache. She had an initial witnessed tonic-clonic seizure followed by multiple subsequent seizures while accompanied by EMS. She was also noted to have severe thoracic back pain. She had a history of multiple rib fractures. She did not smoke, but admitted to drinking 1 to 2 beers daily 6 times weekly. Physical exam was notable for elevated blood pressure at 165/89. She was also found to have diffuse ecchymoses on her arms and legs along with spinal tenderness along the thoracic spine. She had no focal neurologic deficits. Her laboratory studies revealed AST elevation 59 units/L with AST/ALT ratio of approximately 2:1. MRI brain showed no evidence of hemorrhage. MRI of the thoracic spine showed moderate compression fracture of T9 consistent with post-traumatic origin. During her hospital course, the patient's seizures were treated with levetiracetam. She also underwent kyphoplasty of her compression fracture with improvement in her pain post-operatively. Prior to discharge, patient revealed that she had a long history of suffering from intimate partner violence including being hit and beaten by her husband for the past 30 years.

DISCUSSION: Intimate partner violence includes threatened, attempted, or completed physical or sexual violence or emotional abuse by former or current intimate partners whether a spouse, ex-spouse, or dating partner. Such violence is experienced by 35.6 % of women and 28.5 % of men in the United States in their lifetime. Recognizing patients at risk is crucial to help prevent the morbidity and mortality associated with this condition. A variety of health conditions and risk behaviors have been associated with intimate partner violence including stroke, heart disease, arthritis, HIV risk factors, current smoking and heavy drinking. Conditions like irritable bowel syndrome, frequent headaches, chronic pain, depression, anxiety, and insomnia have all been found as consequences of intimate partner violence. Patients may also show physical evidence of trauma not consistent with the history provided. In this case, the patient had multiple risk factors including frequent alcohol use both by history and laboratory studies and history of multiple rib fractures as well as evidence of a traumatic spine fracture. In January 2013, the United States

Preventive Services Task Force released a grade B recommendation for screening women of childbearing age for domestic violence. Multiple screening tools including the HITS (Hurt, Insult, Threaten, Scream), HARK (Humiliation, Afraid, Rape, Kick), and STAAT (Slapped, Threatened, and Throw) have been validated with high sensitivity and specificity for identifying patients at risk for intimate partner violence. Using these simple tools can help open up a larger conversation for patients about an incredibly personal topic. Opening up the conversation with patients will allow physicians and patients to recognize situations of abuse and move towards greater action towards prevention and providing treatment for victims of intimate partner violence.

SEROTONERGIC REACTION MANIFESTING AS DELAYED TOXICITY: RESPONSE TO CYPROHEPTADINE THERAPY Sarashandra Vallabhajosyula¹; Pranathi Sundaragiri¹; Ariel M. Modrykamien^{1,2}. ¹Alegent-Creighton University Medical Center, Omaha, NE; ²Alegent-Creighton University Medical Center, Omaha, NE. (*Tracking ID #1939506*)

LEARNING OBJECTIVE 1: Understanding the clinical presentation and management of serotonin syndrome, highlighting the role for cyproheptadine therapy

LEARNING OBJECTIVE 2: Identifying delayed manifestation of serotonin toxicity manifesting 3 months after medication alteration

CASE: Introduction: Serotonin (5-HT) neurons participate in sleep-wakefulness cycles, mood, food and sexual behaviors, and thermoregulation via the central brainstem midline raphe nuclei and on vascular tone and gastrointestinal motility in the periphery^{1,2}. Serotonin syndrome (SS) is a clinical triad of mental status changes, autonomic hyperactivity and neuromuscular abnormalities mediated via 5HT2A receptors¹⁻³. First reported in 1980s, there were 26,733 cases and 93 deaths in 2002^{2,3}. Case Report: A 53-year-old Caucasian female with past history of diabetes, hypertension, osteoarthritis and depression presented with worsening dyspnea, tremors and loss of balance of one-day duration. Three months prior, the patient developed tremors after increase in sertraline dosage. Review of systems was positive for urinary retention, forgetfulness and cough. Home medications included promethazine, diphenhydramine, citalopram, bupropion, hydrocodone, morphine, metformin and sertraline. Vital signs at presentation—temperature 102.7 °F, heart-rate 103/min, blood pressure 212/183 mmHg, respiratory rate 20/min & oxygen saturation 80 % on ambient air. Examination demonstrated dry mucous membranes, rigid abdominal wall, tachycardia, confusion, disorientation and resting myoclonus. Laboratory studies revealed mild leukocytosis, hyponatremia and acute kidney injury (AKI) with creatinine 4.0 mg/dL (baseline 0.9 mg/dL). A mixed respiratory/metabolic acidosis (pH 7.27), with elevated serum lactate (2.4 mmol/L) and creatinine phosphokinase (CPK) (921 U/L), was noted. Thyroid and liver function testing was normal and imaging studies for chest, abdomen and retroperitoneal regions were unremarkable. Home medications of sertraline, promethazine, metformin and diphenhydramine were held. Patient did not respond to empirical physostigmine therapy for suspected central anticholinergic syndrome. Supportive measures including intravenous hydration, positive pressure airway support, bronchodilator and diazepam therapy were initiated. Patient's labile blood pressure ranging 94 to 224 mmHg was controlled with esmolol as needed. In view of insignificant improvement, cyproheptadine therapy was initiated—loading 12 mg, then 2 mg for 8 doses (total 28 mg). Patient's confusion, myoclonus and dyskinesia resolved with return of baseline renal function confirming a diagnosis of SS. She was transitioned to lower doses of citalopram and bupropion, with no recurrence of symptoms at six-month follow-up.

DISCUSSION: SS is a dose-dependent continuum of clinical manifestations noted in all age groups 1–4, with onset usually immediate with ranges of 4–6 h after initial use, overdose or change in dosing with occasional reports of delayed onset (12 h) in slow release preparations^{2,3}. Since it is a clinical diagnosis, multiple criteria in the past have been used, which were not very specific^{1,3,4}. Currently, Hunter Serotonin Toxicity Criteria (sensitivity 84 %, specificity 97 %), which quotes clonus (spontaneous, ocular and inducible), agitation, diaphoresis, tremor and hyperreflexia as accurate predictors, is applied^{2,4}. Occasionally, hyperreflexia and clonus are absent, which can be explained by the extreme state of muscle rigidity^{3,4}. Bowel sounds, skin discoloration and rapidity of onset help distinguish from alternate diagnoses². Non-specific laboratory findings include leukocytosis, high CPK and low bicarbonate with no correlation to serum serotonin levels. Management entails discontinuation of serotonergic agent and supportive therapy for prevention of respiratory failure, AKI and agitation with intravenous hydration, anxiolytics, chemical paralysis and mechanical ventilation 1–4. Direct-acting sympathomimetic agents and short acting anti-hypertensives are used to treat extremes of blood pressures². Cyproheptadine, a histamine-1 receptor antagonist with non-specific action at 5HT1A and 5HT2A receptors, in a dose of 12–32 mg in a 24-hour period, has shown good response in management of SS. Other agents used include chlorpromazine, olanzapine,

propranolol, bromocriptine and dantrolene, but are currently not recommended. However, further clinical trials are required to validate the use of cyproheptadine in SS^{2,3}. References: 1. SEVERE HYPERBILIRUBINEMIA IN A HEALTHY 18-YEAR-OLD MALE Dennis D. Wang^{1,2}; Chris Chu^{1,2}; David McCants^{1,2}. ¹Baylor College of Medicine, Houston, TX; ²Ben Taub General Hospital, Houston, TX. (*Tracking ID #1935177*)

LEARNING OBJECTIVE 1: Hyperbilirubinemia is a common symptom in newborns and mid-age patients with liver or biliary diseases, but is relatively uncommon in healthy 18-year-olds. It is important to take a complete and thorough family history in teenage patients who presents with acute onset jaundice because hereditary spherocytosis often precipitates bilirubin stones, and the patient may be easily be misdiagnosed with obstructive biliary disease instead. Obtaining a blood smears can also be helpful in making the diagnosis.

LEARNING OBJECTIVE 2: In patients with a functioning liver presenting with hyperbilirubinemia secondary to hemolytic anemia, the hyperbilirubinemia can be predominantly direct rather than indirect. As in this case, the patient initially presented with a total bilirubin of 50.8 mg/dL and direct bilirubin of 38.5 mg/dL, but RUQ ultrasound and CT abdomen did not reveal any signs of biliary obstruction. Therefore, it is important to also work up any patient with direct-bilirubin predominant hyperbilirubinemia for causes that increases bilirubin production.

CASE: An 18-year-old otherwise healthy Hispanic male presents with a 2-week history of RUQ and right flank pain and nausea, which were exacerbated by eating solid food. On the day before admission, he began noticing that his skin and the sclera of his eyes turning bright yellow, which prompted him to come into the emergency room. Over the same time frame, he also noticed that his urine had become darker than usual. The patient denies fevers, chills, diarrhea, constipation, hematochezia, melena, dysuria, unintentional weight loss, drug or heavy alcohol use, recent travels, or any sick contacts. He has no known history of biliary or liver disease. At the emergency room, the patient was found to have a total bilirubin level of 50.8 mg/dL (Ref: 0.2–1.0), direct bilirubin level of 38.5 (Ref: <0.2) mg/dL, and reticulocyte count of 12.1 %. Alkaline phosphatase was only mildly elevated and the patient was not anemic. Coombs tests, hemoglobin electrophoresis, and direct RBC antibody tests were all negative. Upon further inquisition of his family history, the patient's mother reveals that herself and her brothers had a history of jaundice when they were young, and she had her spleen removed at the age of 19 due to an unknown illness. CT abdomen and pelvis and abdominal ultrasound showed only mild hepatosplenomegaly, fatty liver, and cholelithiasis without cholecystitis or any signs of biliary obstruction. We obtained a peripheral blood smear, which showed predominantly spherocytes (70 to 80 %) and a diagnosis of hereditary spherocytosis was made.

DISCUSSION: Hereditary spherocytosis is a relatively common genetic disease affecting 1 in every 5000 people of northern European origin. The most common mutation is autosomal dominant and in the ankyrin gene, which results in RBC membrane instability and loss during exposure to shear force. Common clinical presentations include anemia, splenomegaly, cholelithiasis, and jaundice at an early age. However, as in this case, affected patients may remain asymptomatic until adulthood. In addition to hyperbilirubinemia, laboratory findings may include decreased Hgb with an elevated reticulocyte count, elevated MCHC, RDW, pseudohyperkalemia, and the characteristic spherocytes on peripheral blood smear. The osmotic RBC fragility test only has a sensitivity of about 70 %. Management is primarily focused on providing symptomatic relieve, including surgical splenectomy and cholecystectomy. This case highlights the importance of obtaining a complete and thorough family history and considering the workup of pre-hepatic pathology in young and healthy patients presenting with direct-bilirubin predominant hyperbilirubinemia.

SEVERE HYPONATREMIA IN A PATIENT WITH ESRD CORRECTED BY HYPERTONIC INFUSION WHILE REMOVING ISOTONIC VOLUME FOLLOWED BY HEMODIALYSIS Alexander Pine^{1,2}; Megan S. Lemay^{1,2}; Antony J. Cusano^{1,2}. ¹Yale University School of Medicine, New Haven, CT; ²Waterbury Hospital, Waterbury, CT. (*Tracking ID #1925990*)

LEARNING OBJECTIVE 1: Recognize challenges and options for safe sodium correction in patients with ESRD requiring hemodialysis.

LEARNING OBJECTIVE 2: Correct severe hyponatremia in a patient with ESRD by infusing hypertonic saline while removing isotonic fluid followed by hemodialysis.

CASE: A 56-year old woman with history of schizophrenia treated with clozapine, ESRD of unclear etiology on HD presented with confusion, vomiting, diarrhea, and sodium of 112 mEq/L. Three days prior sodium was 134 mEq/L. Vital signs were unremarkable. She had moderate jugular vein distention of approximately 9–10 cm of water, positive hepatojugular reflux. Breath sounds were distant, inspiratory crackles and expiratory wheezes were heard bilaterally. She had significant edema up to mid-calves in both lower extremities. Potassium was 4.0, chloride 74, bicarbonate 24, serum creatinine 5.71 mg/dL, BUN 28 mg/dL. Plasma osmolality was 240 mOsm/kg. She was not anuric; specific gravity was 1.005. Urine osmolality was 154 mOsm/kg and urine sodium 67 mmol/L. We thought that rapid hyponatremia was the side-effect of clozapine causing psychogenic polydipsia. She was fluid-restricted. Initially, the patient underwent 3 L of isotonic fluid removal by ultrafiltration followed by an infusion of 3% saline. This two-step procedure brought sodium from 112 to 118 mEq/L. Subsequently, adjustments with hypertonic saline and water raised sodium to 124 mEq/L after the period of 48 h. Next, using the dialysate with high sodium concentration of 140 mEq/L, we initiated HD and raised sodium to 130 mEq/L in 3 h. Immediately after HD, water was given to taper sodium to 127 mEq/L. The second HD increased sodium to 132 mEq/L.

DISCUSSION: The patient with ESRD, low ejection fraction of less than 20 % was admitted with severely depressed serum sodium that was thought to be a side-effect of clozapine causing primary polydipsia. The management of hyponatremia in patients with ESRD presents a challenge. This is because the transfer of sodium during hemodialysis can exceed established safe correction rates owing to significant serum-to-dialysate sodium differential. Sodium correction should not exceed the rate of 10 mEq/L/24 h to avoid central pontine myelinolysis, a process in which sudden augmentation in extracellular osmolality by rapid increase of sodium concentration leads to intra-to-extracellular water shift that may cause irreversible damage of CNS neurons. Considering the significant differential between serum sodium and that of dialysate concentrations (112 vs of 140 mEq/L, the lowest available to us), we delayed hemodialysis out of concern that it would correct too rapidly. To avoid rapid correction of sodium in a patient with severe hyponatremia we brought serum sodium closer to that of available dialysate by infusing hypertonic saline while removing isotonic volume. This was done to effectively increase the total body sodium without causing further volume expansion in this patient who exhibited signs of fluid overload. Wendland et al. (2012) described a method to mitigate sodium transfer and thus maintain safe serum sodium correction rate, in which hemodialysis was performed at a slower transfer rates (2 mEq/L/h) while using the dialysate with reduced sodium concentration (130 mEq/L vs 140 mEq/L available to us). Of course, this method prolongs the hemodialysis time. Furthermore, we were concerned with volume status that was consistent with fluid overload. While in euvolemic patients infusion of free water during hemodialysis could be used to achieve safe serum sodium transfer rates, we could not use this approach as our patient was showing signs of fluid excess. Therefore, we used a two-step approach in which we first safely raised serum sodium without expanding the volume, and then followed by safe sodium transfer during hemodialysis. With this case, we describe challenges of the safe rate for sodium correction in patients with hyponatremia in the settings of ESRD, and how to avoid over-correction. Reference: Wendland, et. al. Seminars in Dialysis. 25:1, pp. 82–85, 2012.

SEVERE HYponATREMIA IN BEER POTOMANIA: A CASE FOR CAUTION Kristopher P. Kline¹; Jorge Fuentes¹; Amir Kazory^{1,2}. ¹University of Florida, Gainesville, FL; ²University of Florida, Gainesville, FL. (Tracking ID #1926328)

LEARNING OBJECTIVE 1: Manage severe hyponatremia with careful selection of fluids, monitoring and adjustments.

LEARNING OBJECTIVE 2: Recognize the clinical features for rapid overcorrection of hyponatremia.

CASE: Hyponatremia, defined as a serum sodium level less than 135 mEq/L, is a potentially fatal electrolyte abnormality. Patients with acute severe hyponatremia can present with headache, nausea, vomiting, confusion, disorientation, and lethargy. The syndrome “beer potomania” is used to describe a patient who presents with hyponatremia in conjunction with low daily solute intake and excessive beer drinking. A 63-year-old woman with a past medical history of hypertension, ethanol abuse, and depression presented with a two-day history of worsening confusion and lethargy. Vital signs were within normal range except for a respiratory rate of 24/min. She was diaphoretic, somnolent, oriented only to self, and opened eyes to verbal stimuli and sternal rub. Laboratory studies revealed severe hyponatremia with a serum sodium of 101 meq/L, low serum osmolality of 215 mOsm/kg, urine osmolality of 137 mOsm/kg, and a low urine

sodium of 4 meq/L. Based on her history, clinical presentation, and laboratory values a diagnosis of hyponatremia secondary to beer potomania was made. She was initially treated with 3% hypertonic saline followed by isotonic solutions the rate of which was carefully adjusted according to the rate of serum sodium correction. However, she developed a significant increase in urine output followed by a sudden increase in serum sodium level (124 mmol/L at 24 h) which was successfully managed by administration of hypotonic solutions. Her neurologic symptoms slowly resolved during admission without further complications.

DISCUSSION: Beer potomania represents a normovolemic variant of hyponatremia with appropriate suppression of ADH and urinary dilution. This typically ensues after daily consumption of greater than 5-liters of fluid (approximately 14 cans of beer) given a maximal urinary dilution of 50 mOsm/L with 250 mOsm of obligatory solute loss per day. The disease entity is particularly difficult to manage as the patients are at serious risk of rapid correction of hyponatremia and its neurological sequelae. The appropriately low ADH levels limit free-water absorption in the kidney and explain why these patients could develop brisk diuresis when solute (e.g. IV saline solution) or a high-protein diet is started. In patients with severe symptoms, rapid correction of serum sodium by 4–6 mmol/L with hypertonic saline in the first 6 h is indicated. Slower rate of correction with less than 10 mmol/L in the first 24 h and less than 18 mmol/L in the first 48 h should be enforced to prevent potentially permanent neurologic complications. This case demonstrates the importance of the diagnosis of beer potomania and highlights treatment goals as well as the susceptibility of these patients to present with overcorrection of serum sodium levels despite careful selection of fluids and adjustment of their rate of administration.

SEVERE HYponATREMIA: IS YOUR PATIENT ALCOHOLIC? Dipen Kumar Modi; Hirva Mamdani; Theresa Vettese. Wayne State University, Detroit, MI. (Tracking ID #1939047)

LEARNING OBJECTIVE 1: To recognize Beer Potomania as an uncommon but important cause of hyponatremia in Alcoholics

LEARNING OBJECTIVE 2: To recognize the role of serum and urine osmolality in diagnosing Beer Potomania To recognize key principles of managing Hyponatremia

CASE: A 55 years old African American man with significant past medical history of chronic alcoholism was admitted for confusion and seizures. The patient also had generalized weakness for 5–7 days duration prior to admission. He was drinking 40 oz beer daily for more than 35 years. He had been drinking more beer (around 64 oz) for many weeks prior to admission because of stressful condition in family. His oral intake had been very irregular, reduced and even missed because of heavy drinking. On physical exam, patient was afebrile and normotensive. He appeared confused, severely cachectic and malnourished. Patient had no focal neurologic deficits, jugular venous distension, lower extremity edema, or stigmata of chronic liver disease. Clinically patient did not seem like dehydrated and was not on any diuretic or antipsychotic medication. Laboratory studies revealed severe hyponatremia (96mMol/L). Patient had low serum osmolality (213 mOsm/kg), low Urine Na⁺ (11mMol/L), and low urine osmolality (121 mOsm/kg). Further studies showed severe hypokalemia (3.2mMol/l), hypochloremia (60mMol/L), hypocalcemia (7.3 mg/dl) and hypophosphatemia (1.6 mg/dl), undetectable BUN (<1 mg/dl) and creatinine (<0.1 mg/dl), as well as hypomagnesemia (1.3 mg/dl). Liver function tests, TSH, and serum cortisol levels were unremarkable. Chest x-ray did not show any lung lesion. CT head revealed mild generalized brain atrophy. Finally diagnosis of beer potomania was made based on hyponatremia with relative low serum osmolality and low urine osmolality.

DISCUSSION: Beer Potomania is an uncommon cause of hyponatremia in alcoholic patients. It is a condition characterized by severe hyponatremia without any obvious cause, low serum and urine osmolality, clinical findings consistent with protein malnutrition and consumption of large amount of alcohol. Hyponatremia has been observed in 17 % of chronic alcoholics in the study by Liamis et al. Hypokalemia, mild neurological symptoms (confusion), low BUN, brisk diuresis in response to solute intake and low urine sodium level have also been frequently noticed. Hyponatremia is mainly caused by very high water intake that exceeds excretory capacity. Patients with beer potomania have a history of significant beer drinking in conjunction with poor diet. The net result is very low osmole intake because beer has very little sodium and no protein but has some calories that prevent endogenous protein breakdown. Because obligatory solute loss in a day is approx. 250 mOsm in these patients, with a urinary dilution capability of 50 mOsm/L, water intake greater than 5 l results in hyponatremia. Moreover, ADH levels are frequently suppressed because negative suppression of osmo-receptors from hypotonic serum secondary to excessive beer intake. Patient with beer potomania are at increased of developing Osmotic Demyelination Syndrome because of degree and chronicity of hyponatremia. The goal Sodium increment should be below 10 mEq/L in first 24 h and less than

18 mEq/L in the first 48 h. If the patient has neurological symptoms, correction of sodium level by 1–2 mEq/h in the first 2–3 h is acceptable. If the sodium increment occurs at a rate that exceeds goal, D5W infusion should be started to match urine output. Desmopressin may be considered if diuresis occurs at an excessive rate that the infused D5W is unable to match.

SEVERE MALARIA CAUSING PROFOUND HEMOGLOBINURIA AND ACUTE KIDNEY INJURY James F. Dylewski¹; Jennifer Axelband²; Thong Le³.

¹St. Luke's University Hospital, Bethlehem, PA; ²St. Luke's University Hospital, Bechtelhem, PA; ³St. Luke's University Hospital, Bethlehem, PA. (*Tracking ID #1915761*)

LEARNING OBJECTIVE 1: Recognize the clinical features of Blackwater fever

LEARNING OBJECTIVE 2: Assess the role of artesunate in treatment of malaria

CASE: A 40 year-old, otherwise healthy, African American male presented with episodic fever for 2 weeks. A thorough history yielded that he had visited Nigeria 1 month ago. Prior to his trip, he had obtained atovaquone/proguanil for malaria prophylaxis, but was noncompliant. Upon his return, he was diagnosed with malaria and was treated with doxycycline and hydroxychloroquine. He reported compliance with the medications, but continued to have fevers. Three days elapsed before the patient returned for evaluation. He was subsequently found to be hypotensive, necessitating transfer to our ICU for treatment of septic shock from severe malaria. The patient received aggressive volume resuscitation and vasopressor hemodynamic support. Preliminary laboratory studies showed a creatinine (Cr) of 1.35 mg/dL and hemoglobin (Hgb) 14.0 g/dL. Urinalysis demonstrated small dipstick positive blood without RBC on microscopy. A malaria smear identified the species as Plasmodium falciparum with 24.7 % parasitemia. The patient was given atovaquone/proguanil and the CDC was contacted. Given the severity of his condition, artesunate was obtained from the CDC and administered in conjunction with atovaquone/proguanil. Several hours after receiving the artesunate, the patient became febrile, tachypneic, tachycardic, and encephalopathic necessitating intubation. The patient's urine was noted to change color from clear yellow to opaque, dark red. Blood chemistries 24 h into treatment revealed a Cr of 2.32 mg/dL, Hgb 10.9 g/dL and parasitemia 0.2 %. The patient completed his course of artesunate and atovaquone/proguanil with marked improvement. By day 3, vasopressors were titrated off and he was extubated. By day 7, the patient's Cr improved to 1.30 mg/dL and urine color was dark yellow with moderate dipstick positive blood with only 2–4 RBCs/hpf. The patient was deemed clinically stable and discharged with close outpatient follow up.

DISCUSSION: Malaria is one of the most common infections globally with 300–500 million annual cases worldwide. However, in the US there are less than 2000 cases/year with only about 10 % being considered severe. Fever, rapid developing anemia, acute kidney injury and hemoglobinuria associated with malaria is Blackwater Fever. With prophylaxis, early detection and malaria's domestic eradication in 1951, Blackwater Fever essentially disappeared in the US. It is felt this complication arises from massive hemolysis associated with treating malaria. Though rare, it can progress to renal failure and is associated with higher morbidity and mortality. Artesunate is an intravenous antimalarial agent that is part of a class of drugs referred to as artemisinins. Artemisinins are believed to work by inhibiting DNA replication and transcription in Plasmodium species. Though considered a first-line therapy in most malaria endemic countries, in the US, artesunate is an orphan therapy for severe P. falciparum and can only be obtained from the CDC. Currently, the indications for obtaining artesunate are: severe malaria disease, high level of parasitemia, inability to take oral medication, lack of timely access to intravenous quinidine, quinidine intolerance or contraindications, or failure of quinidine therapy.

SEVERE REFRACTORY HYPERCALCEMIA IN A RARE CASE OF B-CELL PROLYMPHOCYTIC LEUKEMIA Kah Poh Loh¹; Saurabh Dahiya²;

Karan Singh¹; Leslie Howard²; Maura J. Brennan³. ¹Baystate Medical Center/Tufts University, Springfield, MA; ²Baystate Medical Center/Tufts University, Springfield, MA; ³Baystate Medical Center/Tufts University, Springfield, MA. (*Tracking ID #1942036*)

LEARNING OBJECTIVE 1: Recognize the clinical presentations of prolymphocytic leukemia (PLL)

LEARNING OBJECTIVE 2: Evaluate PLL using a systematic approach

CASE: An octogenarian presented with 2 weeks of progressive weakness, subjective fever and left upper quadrant pain. He had no history of any hematologic disorder but physical examination revealed massive splenomegaly with no hepatomegaly. He had a marked lymphocytosis with immature cells and smudge cells on the peripheral smear. A CT abdomen and pelvis verified splenomegaly and bulky lymphadenopathy. An EBV test was positive; flow cytometry revealed CD5-, CD19+ and CD20+, monotypic, kappa-restricted cells consistent with a monoclonal B-cell malignancy. He was diagnosed with a B-cell prolymphocytic leukemia/lymphoma. Shortly thereafter he became weak and

delirious with worsening leukocytosis, hypercalcemia (17.3) and hyperuricemia (12.4) secondary to his leukemia. He was aggressively hydrated and given furosemide, dexamethasone, calcitonin and zoledronic acid with minimal improvement in his calcium level. Comfort measures were instituted and he died shortly thereafter.

DISCUSSION: This case is special in that the authors report the first case of refractory hypercalcemia due to B-PLL in an elder. B cell prolymphocytic leukemia (PLL) is rare; it is characterized by marked leukocytosis and splenomegaly and comprises less than 1 % of B cell leukemias. It was first described in the 1970s. Older men are at higher risk and progression can be very rapid. The disease usually becomes clinically apparent within 1–2 years; the majority of patients present with B-symptoms and splenomegaly. Diagnosing PLL relies on identification of promyelocytes in the peripheral blood. Therapy is only indicated for patients with symptomatic and progressive disease. Rituximab, fludarabine and anthracycline monotherapy (or combination therapy) are used to treat PLL but the prognosis is worse than CLL; the median survival is 65 months. Our patient's B-PLL was complicated by hypercalcemia which was unresponsive to all treatment. This precluded any attempt at chemotherapy. To our knowledge this is the first reported case of B-PLL presenting with severe refractory hypercalcemia.

SEVERE RHABDOMYOLYSIS FROM INFLUENZA A PHINI (2009) VIRUS INFECTION: SUSPECT EARLY AND TREAT AGGRESSIVELY Emily R. Haggerty; Amit Sharma; Viren Kaul; Omar Mousa; Phillip Aleksiejuk; Karthikeyan Sitaraman. SUNY Upstate Medical University, Syracuse, NY. (*Tracking ID #1939022*)

LEARNING OBJECTIVE 1: Diagnose rhabdomyolysis in influenza infection despite the absence of previously reported clinical risk factors of influenza severity for effective management.

LEARNING OBJECTIVE 2: Recognize that high creatine kinase (CK) levels with early initiation of renal replacement therapy (RRT) positively impacts clinical outcomes and length of hospital stay.

CASE: A previously healthy 31yo African American male presented with low back pain radiating to the lower extremities for 1 week and fever for 1 day. Additional history included recent upper respiratory tract infection associated with diffuse body aches 1 week prior to admission. Our high clinical suspicion for influenza was later confirmed by respiratory panel positive for influenza A pH1N1 (2009) infection. By this time, the patient's renal function had deteriorated from a creatinine of 2.2 mg/dL to 7.2 mg/dL with severe transaminitis. Initial CK levels were normal but rising on the clinical suspicion of rhabdomyolysis, serial CK levels were ordered. The subsequent level was 615840 U/L (peak 677560 U/L). Interestingly, serum electrolytes were normal except for hyperphosphatemia and, despite severe myoglobinuria, the patient's urine output remained normal. We excluded other vascular, toxic and metabolic causes for rhabdomyolysis leading to a diagnosis of severe influenza induced rhabdomyolysis. The hospital course was eventually complicated by resistant hyperkalemia and normal anion gap metabolic acidosis. Ultimately, the patient required RRT. CK levels improved, renal function stabilized and the patient continued to respond well to anti-virals and supportive management. There was no indication for intensive care support at any point during the hospital course.

DISCUSSION: The incidence of influenza-induced rhabdomyolysis has been poorly reported in the literature. In addition, internists rarely encounter such a serious complication. Our case highlights the heterogeneity of the presentation of influenza rhabdomyolysis, with absence of the traditional risk factors for severe influenza complications including extremes of age, multiple medical comorbidities, immunosuppression, pregnancy, morbid obesity and residence in a chronic care facility. Recent data refutes a correlation between these risk factors for severe influenza and actual outcomes. Furthermore, published case reports of influenza-induced rhabdomyolysis with acute renal failure are primarily in young, healthy individuals, supporting our observation. Maintaining a high level of suspicion for influenza rhabdomyolysis in addition to aggressive monitoring at any age or health status is essential for preventing poor outcomes. More specifically, CK has been proposed as a biomarker of H1N1 infection severity. Correlation between elevated CK and morbidity has been observed with twofold increase in RRT requirement in patients with CK \geq 500 UI/L. Since RRT decreases CK levels while simultaneously improving symptomatology, we highly support the initiation of early RRT in patients with elevated CK in order to decrease morbidity and length of hospital stay. Future research is required to quantify appropriate CK levels for the initiation of RRT, regardless of other indications.

SEVERE SIRS FOLLOWING 23-VALENT PNEUMOCOCCAL VACCINATION IN A PATIENT WITH BEHÇET'S DISEASE Vijay Kotchela²; Kevin D. Hauck¹; Matthew Shaines¹. ¹Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine, Bronx, NY. (*Tracking ID #1939218*)

LEARNING OBJECTIVE 1: -Understand common reactions to the 23-valent pneumococcal vaccine

LEARNING OBJECTIVE 2: -Recognize the role of streptococcal antigens in Behcet's disease

CASE: A 41 year-old man with a history of Behcet's disease treated with azathioprine presented with 1 day of fevers, rigors and severe right arm and shoulder pain. His symptoms started 12 h after receiving the 23-valent pneumococcal vaccine in his right deltoid. Vital signs on admission were notable for temperature of 104.8° Fahrenheit and heart rate of 120. There was full range of motion at the shoulders. There was a 12 cm poorly demarcated area of erythema, warmth, fullness, and exquisite tenderness to palpation over the right deltoid. Labs were notable for C-reactive protein of 24 mg/dL and white blood cell count of 20,000. Blood cultures showed no growth. A sonogram of the right deltoid was unremarkable. He was treated supportively with intravenous fluids and acetaminophen. By hospital day two, his arm pain and fevers had resolved, and he was discharged home without further incident.

DISCUSSION: Behcet's disease is a rheumatological condition found most commonly in those of Turkish or Middle Eastern descent. Behcet's may cause vasculitis of vessels of all sizes, and classically manifests as recurrent oral, genital and skin ulcerations. It may also involve the brain, heart, kidneys, lungs, joints and eyes and can progress to blindness, severe gastrointestinal bleeding, and permanent neurological deficits. Treatment depends on the extent of disease progression, but generally requires immunosuppression with glucocorticoids followed by azathioprine, infliximab or cyclosporine. The Centers for Disease Control and Prevention recommend administration of the 23-valent pneumococcal vaccine to immunocompromised adults, including those patients taking immunomodulating agents. About 50 % of adults will experience mild reactions to this vaccine, usually a local inflammatory response at the site of injection. Systemic reactions, including fevers and arthralgias, occur in less than 1 % of recipients. Severe reactions, such as seen in this patient, are exceedingly rare. To our knowledge, this is the fifth reported case of a severe systemic inflammatory response after administration of the 23-valent pneumococcal vaccine in a patient with Behcet's disease. Prior cases occurred similarly, with rapid onset of fevers to greater than 104, severe pain at the injection site, rigors and C-reactive protein levels of 16 to 40 mg/dL. As in our patient, symptoms mostly resolved by 48 h with supportive care. The origins of Behcet's disease are incompletely understood, but are known to include genetic factors, such as HLA-B51, and alterations in innate and cellular immunity in response to environmental antigens. Of particular interest are streptococcal species. When compared to controls, Behcet's patients have significantly higher titers against certain species of streptococcus. Exposure to these antigens, such as from skin testing, causes upregulation of the pro-inflammatory cytokines IL-6 and TNF-alpha which in turn can lead to hypersensitivity reactions and exacerbations of Behcet's. Hypersensitivity reactions to streptococcal antigens are frequent enough that is part of the Japanese diagnostic criteria for Behcet's. A reaction to one of the streptococcal antigens in the 23-valent pneumococcal vaccine would explain our patient's severe SIRS response.

SHIGELLOSIS AS A SEXUALLY TRANSMITTED DISEASE IN A HIV INFECTED MALE Matthew McCarra. University of California San Diego, San Diego, CA. (Tracking ID #1939768)

LEARNING OBJECTIVE 1: Recognize Shigella as a sexually transmitted infection in the men who have sex with men population

LEARNING OBJECTIVE 2: Recognize the limitations of stool cultures in diagnosis of Shigella dysentery

CASE: A 36 year-old man with a history of AIDS, off HAART due to non-compliance (CD4: 55 and viral load 120,000), presented to our emergency department for diarrhea and crampy abdominal pain. He endorsed two months of more than 20 loose, watery stools daily without blood or mucus and he had been admitted on two previous occasions for these complaints. He denied fevers, chills, nausea, or vomiting but endorsed recent 10 lb weight loss. Prior workup included multiple stool studies that showed blood and moderate white blood cells however negative for infectious source on stool culture negative tests for Cyclospora, Clostridium difficile, and Giardia which were negative. A colonoscopy showed severe colitis with erythema, friability, and adherent white exudate, without discrete ulceration. Biopsy of the colon was performed that demonstrated acute colitis with erosions and pseudomembranous exudate. A single cell stained positive for CMV. During that admission HAART—darunavir and abacavir/lamivudine—and gancyclovir (5 mg/kg) for presumptive CMV colitis was initiated with notable improvement in his symptoms. On discharge he was transitioned to oral valgancyclovir (900 mg BID). He did well at home for 3 weeks before recurrence of symptoms when he represented at time of the presentation of discussion. He was sexually active with men with a new sexual

partner a month prior to onset of the symptoms. He denied any travel outside of the country but had recently traveled to Philadelphia. His medications included darunavir abacavir/lamivudine, valgancyclovir, azithromycin, trimethoprim/sulfamethoxazole, fluconazole, and promethazine. He was admitted for additional workup of severe diarrhea and pain control. At time of admission stool cultures were repeated, blood cultures were obtained, and he was transitioned back to IV gancyclovir with concern of malabsorption given severe duodenitis/colitis observed on prior imaging. Vital signs were normal and physical exam was remarkable for a cachectic male, temporal wasting, hyperactive bowel sounds with severe abdominal tenderness to palpation diffusely. There was no rebound tenderness, rigidity, or involuntary guarding. Admission labs were remarkable for K 2.8 mmol/L, creatinine to 2.11 mg/dL from baseline of 0.8 mg/dL. Initially his symptoms failed to improve and his pain persisted requiring large doses of IV hydromorphone. On hospital day 6, four of four admission blood cultures came back positive for *Shigella flexneri* resistant to amikacin, ampicillin, cefuroxime, gentamicin, and trimethoprim/sulfamethoxazole. He was started on IV ceftriaxone 1 g daily with notable improvement and completed a 2 week course at a skilled nursing facility.

DISCUSSION: *Shigella* is a common cause of bacterial associated diarrhea with more than 400,000 cases estimated in the United States every year. Clinical manifestations typically include diarrhea, abdominal pain, hematochezia, and fever. *Shigella* is the third leading cause of bacterial diarrhea in the United States. HIV positive individuals are at increased risk of shigellosis, with highest risk among men who have sex with men (MSM). *Shigella* was first recognized as a sexually transmitted disease in the MSM population in the 1970s with direct oral-anal contact as the primary risk factor. As in our patient, increasing antimicrobial resistance rates, >90 % in one study, have been found particularly to doxycycline, tetracycline, aminoglycosides, cephalosporins, and trimethoprim/sulfamethoxazole. Stool culture is considered the gold standard for diagnosis however remained negative in the presented patient despite multiple cultures. One study demonstrated rates of isolation to be 11–12 % which poses a significant barrier to diagnosis of the disease and subsequent treatment. The present case highlights the need for heightened physician awareness of *Shigella* as an STD in individuals partaking in oral-anal sexual practices. Furthermore, if suspicion for Shigellosis is high, repeated stool testing may be necessary given poor rates of isolation.

SHOSHIN BERIBERI MASQUERADE AS SEPTIC SHOCK Gautam George¹; Fabian Reimold¹; Carey C. Thomson². ¹Mount Auburn Hospital- Harvard Medical School, Cambridge, MA; ²Mount Auburn Hospital- Harvard Medical School, Cambridge, MA. (Tracking ID #1939956)

LEARNING OBJECTIVE 1: To recognize shoshin beriberi which is a fulminant form of thiamine deficiency and its manifestations in a critical care setting

LEARNING OBJECTIVE 2: To understand the pathophysiology of thiamine deficiency causing lactic acidosis and cardiovascular instability

CASE: A 65 year old woman with a history significant for incarcerated ventral hernia repair complicated by enterocutaneous fistulae managed conservatively with bowel rest and total parenteral nutrition for 2 months, presented with lethargy, abdominal pain and changes in mental status. Initial findings were significant for profound hypotension, tachycardia, hypoxia and lactic acidosis. She was admitted to the intensive care unit for management of presumed septic shock. Repeated physical examinations, radiologic and laboratory examinations did not yield a source of infection. Broad spectrum antibiotics, aggressive fluid resuscitation, and vasopressors were initiated. Significantly elevated lactate levels persisted despite resuscitation and stabilization. Due to persistent mental status changes, magnetic resonance imaging of the brain was performed which revealed an abnormal signal in the thalamus and dorsal midbrain. A presumed diagnosis of Wernicke's encephalopathy from thiamine deficiency was made and intravenous thiamine was started. Subsequently, her hemodynamics improved and lactic acidosis resolved with concurrent improvement in her mental status.

DISCUSSION: In our case, we report a patient who had been on total parenteral nutrition without adequate thiamine replacement for a prolonged duration that resulted in severe thiamine deficiency. Thiamine deficiency, which is commonly seen in alcoholics, can also be present in critically ill patients. Manifestations of this nutritional disorder can be varied and can range from polyneuropathy, cardiovascular disease, neurological changes as seen in Wemicke-Korsakoff syndrome and severe lactic acidosis. Fulminant cardiovascular manifestations of thiamine deficiency include hypotension, tachycardia and lactic acidosis and is referred to as Shoshin beriberi. Thiamine is an essential co-factor in important de-carboxylation reactions in the Krebs cycle and decrease in its activity can lead to decrease in pyruvate formation and buildup of lactate that leads to mitochondrial dysfunction. It is important that this disorder be considered in critically ill patients with potential predisposing risk factors, as early diagnosis and treatment can result in preventing hemodynamic compromise and life threatening acidosis.

SICK SINUS SYNDROME TREATED WITH AN ANTIBIOTIC Ahmet A. Oktay; Harvey Friedman. Presence St. Francis Hospital, Evanston, IL. (*Tracking ID #1935012*)

LEARNING OBJECTIVE 1: Increasing the awareness about an atypical presentation of Lyme carditis.

LEARNING OBJECTIVE 2: Recognizing the importance of timely diagnosis and appropriate management of Lyme carditis.

CASE: A 59 y/o male patient presented to the emergency department because of dizzy spells and near-syncope experienced multiple times a day for the past 3 weeks. His symptoms were brief (<30 s) and paroxysmal with no association with any certain activity. He did not have any chest pain, shortness of breath, palpitations or fainting spells and denied any similar complaints in the past. He had a past medical history of hypertension for which he was taking Lisinopril 5 mg daily. He was also on supplemental fish oil, coenzyme Q and flax seed. He had no known allergies and his family history was non-contributory. He lived with his family in Chicago, drank ~1 bottle of wine every week and had no history of cigarette smoking or substance abuse. He reported going on a hiking trip in Upstate New York in September, which was a month ago. Right after returning from this trip, he developed erythematous rash on both arms, which lasted for a couple days and was accompanied by generalized fatigue, subjective fever and arthralgia in multiple joints. On examination, the temperature was 36.9 °C, the blood pressure 156/87 mmHg and the heart rate 64 bpm. His physical exam was normal except irregular heart rhythm. His ECG showed sinus bradycardia (ventricular rate: 56 bpm) with first-degree atrioventricular (AV) block and a sinus pause (3 s) with junctional escape beat. Initial laboratory workup including CBC, electrolytes, TSH and troponin ($\times 3$) were all within normal limits. After admission to the hospital, he continued to experience paroxysmal lightheadedness episodes frequently and these were accompanied by sinus pauses (3 to 7 s) on telemetry. Transcutaneous pacing pads were placed but he did not require any external pacing. Echocardiography was done which did not show any structural or functional cardiac abnormalities except mild mitral and aortic regurgitation. Although there was no recollection of tick-bite, history of skin rash, constitutional symptoms and arthralgia following a hiking trip, presence of first degree AV block and absence of any signs of structural and ischemic heart disease led us to the diagnosis of Lyme carditis as the cause of symptomatic sick sinus syndrome in our patient. He was started on IV ceftriaxone. The diagnosis of Lyme disease was later confirmed by serologic testing; ELISA was positive for IgG antibody and Western Blot positive for IgM and IgG antibodies. The patient showed slow but progressive improvement throughout his 14-day hospital stay. Sinus pauses became shorter and less frequent and the symptoms resolved. However, first degree AV block persisted. He was discharged home on oral doxycycline.

DISCUSSION: Lyme disease is a tick-borne systemic disease caused by the spirochete *Borrelia burgdorferi*. Cardiac involvement is seen in 4 to 10 % of patients with Lyme disease. The cardinal manifestation of Lyme carditis is self-limited conduction system disease, most commonly involving AV node. Additionally, endocarditis, myocarditis, pericarditis or tachyarrhythmias have been reported. The unique aspect of our case is the clear association between Lyme carditis and symptomatic sick sinus syndrome with sinus pause, in addition to AV node dysfunction. Lyme carditis is well known to cause AV node dysfunction. But there have been only a few case reports describing sick sinus syndrome induced by Lyme disease. Treatment options for Lyme carditis have not been validated with randomized controlled trials. However, if clinical suspicion is high as was in our case, antibiotic therapy should be initiated without waiting for lab confirmation. We think that; being aware of atypical presentations of Lyme carditis can help physicians with timely diagnosis of this treatable disease and save patients unnecessary invasive diagnostic and therapeutic procedures.

SICK TO YOUR STOMACH: IATROGENIC BOWEL ANGIOEDEMA Christopher Velez; Eric Stevens; Robert L. Goodman. Montefiore Medical Center, Bronx, NY. (*Tracking ID #1939114*)

LEARNING OBJECTIVE 1: Review the epidemiology of angioedema.

LEARNING OBJECTIVE 2: Recognize angiotensin-converting enzyme inhibitor (ACE) inhibitor-mediated bowel angioedema as a cause of gastrointestinal distress

CASE: A 52-year-old African American man with a history of ischemic cardiomyopathy in the setting of hypertension, hyperlipidemia, type 2 diabetes mellitus, and active tobacco abuse presented with 2 weeks of abdominal discomfort and diarrhea along with several hours of oropharyngeal edema. The patient stated he usually had one or two well-formed bowel movements every day; recently, he had six loose-to-watery bowel movements daily. His diarrhea was non-mucoid, non-bloody, and there were no constitutional symptoms. He had no travel history, sick contacts, dietary changes, or antibiotic use. When the patient additionally developed acute tongue swelling, he presented to the emergency department.

His medications included aspirin, metoprolol, lisinopril, furosemide, spironolactone, and atorvastatin; there were no recent changes. His physical exam was remarkable for tachycardia, dry mucous membranes, and an asymmetric swelling of the tongue without any localized erythema or urticaria. Although there was no respiratory stridor, diffuse abdominal discomfort was present. Laboratory studies revealed a leukocytosis of 12.1 k/uL, normal liver tests, and unremarkable serum amylase and lipase levels. With discontinuation of lisinopril for 48 h and subsequent administration of prednisone and diphenhydramine, the patient's tongue swelling and gastrointestinal distress completely resolved.

DISCUSSION: Angioedema is a clinical phenomenon defined both by its acuity and discrete anatomic localization. Once hereditary angioedema is no longer being considered, only 20–40 % of evaluations are diagnostic. The association between angiotensin-converting enzyme (ACE) inhibitors and angioedema is classic, but it occurs in less than 1 % of patients taking these agents; angiotensin receptor blockers, calcium channel blockers, nonsteroidal anti-inflammatory drugs, antibiotics, and opiates also have been implicated. Yet, there has been an estimated 67 % increase in ACE inhibitor-mediated angioedema over the course of 2005 through 2009 correlating with a three-fold increase in the use of these agents. Risk factors for ACE inhibitor-mediated angioedema, as in the case of this patient, include African ancestry and a history of smoking; other reported risk factors are elderly age, and female gender. Even though the majority of patients report symptoms involving the lips and/or the tongue, angioedema can impact diverse sites including the bowel. Manifestations of visceral angioedema are typically underappreciated and likely underreported, making it difficult to determine the true incidence. Additionally, abdominal symptoms are typically non-specific such as pain, nausea, vomiting, and diarrhea. While visceral involvement may be detected radiographically, the strongest proof of the correct diagnosis of iatrogenic bowel angioedema remains a symptom-free clinical course after discontinuation of the offending agent. This patient experienced simultaneous resolution of gastrointestinal distress and oropharyngeal swelling with no further recurrence noted during subsequent visits to our institution after lisinopril had been stopped. This case illustrates not only the greater consideration that that should be given to ACE inhibitor-mediated angioedema given the increasing use of these agents, but also the importance of diagnosing iatrogenic angioedema beyond the oropharynx which may yield more rapid symptomatic relief without the need for expensive and invasive testing.

SICKLE CELL INTRAHEPATIC CHOLESTASIS: REVERSAL OF HEPATIC FAILURE WITH AGGRESSIVE EXCHANGE TRANSFUSION IN A REFRACTORY CASE Musa A. Sharkawi; Noormuhammad Abbasakoor; Amy Tien; Robert R. Faust; Atoussa Goldar-Najafi. Lahey Hospital & Medical Center, Burlington, MA. (*Tracking ID #1919578*)

LEARNING OBJECTIVE 1: Recognize the causes of liver dysfunction in a sickle cell anemia patient

LEARNING OBJECTIVE 2: Manage patients with sickle cell intrahepatic cholestasis

CASE: A 22 year old Jamaican male with sickle cell disease (HbSS), presented with crampy abdominal pain, scleral icterus, epistaxis, tender hepatomegaly and found to have labs significant for a total bilirubin of >60 mg/dL, direct bilirubin of 43.5 mg/dL, White Blood Cell Count of 19,000, haemoglobin S (HbS) level of 26.7 % and International Normalized Ratio (INR) of 8. He was transferred to us from an outside hospital for further management of liver failure 7 days after a cycle of exchange transfusion was unsuccessful in reversing his hemorrhagic diathesis. He was treated with aggressive supportive therapy which constituted high flow oxygen, intravenous fluid hydration and daily folic acid supplementation. His coagulopathy required multiple fresh frozen plasma (FFP) transfusions and vitamin K supplementation. His symptoms were unremitting, hence a transjugular liver biopsy was performed to discern the underlying pathology. This was very remarkable for hepatic parenchyma with marked sinusoidal dilatation containing densely packed aggregates of “crescent shaped” red blood cells and hepatocanalicular cholestasis [Figures 1–2]. A further cycle of exchange transfusion was then performed with a lower HbS level goal of <10 %. His HbS level post-exchange transfusion was 8.6 % after which the coagulopathy and liver function gradually improved and the patient was discharged home on day 11 of hospitalization.

DISCUSSION: Sickle cell disease is a relatively common condition in populations of African descent that presents with numerous manifestations of varying severities. Common manifestations of hepatobiliary disease in sickle cell anemia include cholelithiasis, viral infection, iatrogenic hemochromatosis, vascular occlusions, hepatic sequestration and acute sickle hepatic crisis all under the umbrella term of “Sickle Cell Hepatopathy” [1]. Sickle cell intrahepatic cholestasis represents a potentially lethal and exceedingly rare variant of sickle hepatic crisis with only 18 cases described in the literature thus far. The underlying pathology is thought to be extensive sickling within the hepatic sinusoids leading to widespread ischemic damage [2]. Patients typically present with intense jaundice, tender hepatomegaly, coagulopathy and extreme hyperbilirubinemia which can progress to hepatic encephalopathy

and florid renal failure. Current literature advocates early exchange transfusion as the treatment of choice with a HbS goal of less than 20–30 % [3–4]. In our experience, expeditious recognition and aggressive intervention with exchange transfusion HbS goal of <10 % and intensive supportive care can result in a favorable outcome in refractory cases.

SINUSITIS CAUSING LEFT SIDED HEMIPARESIS Neal George. Conemaugh Memorial Medical Center, Johnstown, PA. (Tracking ID #1943143)

LEARNING OBJECTIVE 1: How to differentiate possible etiologies to the pathogenesis of brain abscesses.

LEARNING OBJECTIVE 2: How to approach adult patients with brain abscess.

CASE: 65 year old Caucasian female with a history of insulin dependent diabetes mellitus, hypertension, and hypothyroidism presented to the emergency department via private car with complaints of a 3 day history of leaning towards the left side with progressive left sided weakness. No preceding fever or trauma. The patient presented with stable vital signs and with a Glasgow coma scale of 15. No dysarthria was present. Physical exam was remarkable for a 0-1/5 motor strength in the left upper and lower extremity with intact sensation throughout. Admission WBC was 7.3 thousands/cumm with a differential significant for 68 % neutrophils. The remainder of the admission laboratory studies were unremarkable. CT head revealed a 2.2 cm mass in the right cerebral hemisphere with moderate adjacent vasogenic edema without midline shift or hydrocephalus and no acute intracranial hemorrhage was noted. MRI of the brain revealed a peripherally enhancing mass measuring $2.4 \times 1.8 \times 2.3$ cm located in the high right cerebral hemisphere with surrounding vasogenic edema. There was also membranous thickening and/or soft tissue density posterior-inferior aspect of the left maxillary sinus. The patient was evaluated by neurosurgery who performed a image guided craniotomy with excision of deep frontoparietal mass on the fourth day of admission. Surgical pathology of the frozen section revealed acute necro-inflammatory debris with some atypical cell clusters. Culture of the brain tissue resulted in pansensitive growth of *S. intermedius* and *S. constellatus* on day number seven. Blood and urine cultures remained negative. Transthoracic echocardiogram revealed a patent foramen ovale by and Atrial septal aneurysm by color flow doppler. The patient was treated with Decadron 8 mg IV every 6 h and Ceftazidime 1 g every 8 h. Subsequent imaging with dedicated CT of the sinuses revealed ethmoid and maxillary mucosal thickening consistent with sinusitis which was thought to be the possible etiology as previous reports corroborate cerebral abscess formation via intracranial extension from sinogenic sources.

DISCUSSION: Brain abscesses remain a consideration despite improvements in detection and treatment of sinusitis. Three mechanisms have been eluded to as etiologies for seeding brain abscesses. (1) Direct extension: infections stemming from the sinuses, teeth, middle ear, or mastoid may gain access to the venous drainage of the brain via valveless emissary veins that drain these regions. (2) Hematogenous dissemination from distant infection sites often results in multiple brain abscesses. (3) Following penetrating head injury or neurosurgery. However, up to 30 % of abscesses are crytogenic and have no clear source. Upon review of the current literature, there is a single case report of a patent foramen ovale and atrial septal aneurysm presenting with *Streptococcus constellatus* brain abscess. Jan et al. describes a case of 47 year old white male with patent foramen ovale with oral flora causing a *S. intermedius* brain abscess. However the patient reported here had a single solitary cerebral abscess and negative blood cultures making hematogenous spread an unlikely etiology. *S. intermedius* infection tended to be associated with hematogenous spread or were deepseated, whereas those do to *S. constellatus* were more often superficial. *S. constellatus* had more of a predilection to cause odontogenic and intra-abdominal disease. This patient's brain abscess was likely due to maxillary and ethmoid sinusitis via direct extension to the brain via venous drainage. Previous studies have shown that there is a greater predilection for *S. intermedius* and *S. constellatus* to generate cerebral abscesses. Brain abscesses larger than 2.5 cm, stereotactic aspiration or open brain biopsy with evacuation should be strongly considered for microbiological diagnosis which is helpful as given the wide range of possible pathogens and the prolonged course of IV antibiotics. One approach has been to treat neurologically stable patients with early infections with IV antibiotics alone. Aspiration can be attempted when the infection appears more encapsulated and liquefied, to maximize the yield of an aspiration procedure. Large abscesses (>2.5 cm) should generally be

aspirated or excised. There is unfortunately no studies evaluating empiric therapy for cerebral abscess which may be appropriate given the number of different pathogens but those associated with paranasal sinusitis, otitis, or mastoiditis can be empirically treated with third-generation cephalosporins (ceftriaxone, ceftizoxime) combined with IV metronidazole.

SJOGREN'S SYNDROME-ASSOCIATED NEUROPATHY AND CIRRHOSIS

Lillian Chen; Phillip S. Ge; Digish D. Shah. University of California- Los Angeles Medical Center, Los Angeles, CA. (Tracking ID #1940157)

LEARNING OBJECTIVE 1: Recognize that in the majority of patients with Sjogren's syndrome-associated neuropathy, the neurologic manifestations precede the sicca symptoms.

LEARNING OBJECTIVE 2: Recognize that Sjogren's syndrome can rarely cause cirrhosis.

CASE: A 56 y.o. female with history of hypothyroidism, anemia, and thrombocytopenia presented with a 1 year history of unilateral left-sided numbness that gradually progressed to left-sided weakness and numbness of the right foot. She denied any history of heavy alcohol or drug use. Neurological examination showed 3/5 strength in the proximal left lower extremity, 4/5 strength in the distal left lower extremity, 4/5 strength in the left upper extremity, 5/5 strength in the right upper and right lower extremities, absent sensation in the left upper and bilateral lower extremities, and areflexia of the three affected extremities. The remainder of her physical examination was unremarkable. Labs were notable for white blood cell count $2.9 \times 10^3/\mu\text{L}$, hemoglobin 9.6 g/dL, platelets $41 \times 10^3/\mu\text{L}$, alkaline phosphatase 230U/L, AST 38U/L, ALT 24U/L, total bilirubin 0.6 mg/dL, albumin 3.0 g/dL, INR 1.2. TSH was 7.8 $\mu\text{IU}/\text{mL}$ with normal fT4. MRI head/neck revealed multiple parotid cysts. Abdominal ultrasound revealed cirrhosis. On hospital day two, she had massive hematemesis and EGD showed bleeding esophageal varices that were banded. Subsequent laboratories showed ANA >1:1280, positive anti-SSA, and low C3 and C4; other rheumatologic workup including cryoglobulins was negative. HIV, HTLV-1, viral hepatitis panel, anti-mitochondrial and anti-smooth muscle antibodies were negative. Liver biopsy showed macrovesicular steatosis and bridging fibrosis compatible with lupus-related liver disease. CSF studies were normal. EMG/NCS showed sensorimotor polyneuropathy with predominantly axonal features. Sural nerve biopsy showed axonal degeneration and myelinated fiber loss. She was thus diagnosed with mononeuritis multiplex. Schirmer test was positive. Parotid gland biopsy was ultimately non-diagnostic; however she met criteria for Sjogren's syndrome, as she also endorsed dry eyes and mouth starting 1 month prior to admission. She was started on pulse steroids with some improvement in strength and was transitioned to prednisone and ultimately started on rituximab.

DISCUSSION: Neurologic involvement occurs in about 20 % of patients with primary Sjogren's syndrome. The presentation can be diverse, with sensory ataxic neuropathy and painful sensory neuropathy being the most common. However, mononeuritis multiplex and other neuropathies can also be seen. Even though dry eyes and mouth are the most common symptoms in patients with Sjogren's syndrome, patients can have debilitating neuropathy as the initial presentation. A majority of patients develop neuropathy prior to the formal diagnosis of Sjogren's syndrome. Sjogren's syndrome should thus be considered in the evaluation of peripheral neuropathy despite the absence of classic sicca symptoms. Approximately 40 % of patients with primary Sjogren's syndrome may have abnormal liver chemistries; however they are usually asymptomatic or have subclinical disease. The most common diagnoses, when found, are primary biliary cirrhosis, autoimmune hepatitis, and hepatitis C infection. Primary Sjogren's syndrome-associated cirrhosis is considered very rare, however once detected it should be treated similarly to cirrhosis from other etiologies.

SKIN NODULES IN A PATIENT WITH RHEUMATOID ARTHRITIS... COMMON OR DEADLY? Crystal Hlaing; Ryan E. Jones; Tara Norris. Methodist Dallas Medical Center, Dallas, TX. (Tracking ID #1940175)

LEARNING OBJECTIVE 1: Review common dermatologic manifestations of rheumatoid arthritis.

LEARNING OBJECTIVE 2: Be able to differentiate similar-appearing dermatologic conditions associated with rheumatoid arthritis.

CASE: A very pleasant 80-year-old Caucasian woman with a past medical history of RA and hypertension presented to the emergency department (ED). She stated that a rash had started on her left thigh 1 month prior to this ED visit. It had progressed to involve the right thigh and right upper arm, as well as distal interphalangeal joints and finger tips of both hands. The patient was given a 4-week course of amoxicillin-

clavulanate for presumed cellulitis approximately 2 weeks prior to admission. She did not have any improvement with this treatment, however, and in fact experienced progression while on the antibiotic. The patient complained of pain and discomfort in the affected areas, but denied any fever or chills. She had been on methotrexate (MTX) and prednisone prescribed by her rheumatologist for several years. She was also taking a calcium supplement and valsartan/hydrochlorothiazide. She denied any exposure to gadolinium or having an MRI in the past. She reported allergy to sulfa medications. She denied any toxic habits, poor living conditions, or family history of skin disorders. On exam, the patient was afebrile and nontoxic appearing. She had marked erythema and patchy induration of her bilateral inner thighs, with a 1 cm × 1 cm area of skin necrosis over her left inner thigh. The skin on the extensor aspect of her right upper arm was erythematous and swollen and had an extensive area of induration. Both the patient's palms and the fingertips of her right hand were also affected. There was a 0.5 cm × 0.5 cm subcutaneous nodule at the tip of her right second digit. All affected areas were tender but lacked significant warmth to the touch. The patient's laboratory studies were notable only for mild anemia (hemoglobin of 10.0), corrected calcium of 10.3 (normal: 8.4–10.2), and phosphorous of 2.6. She had no leukocytosis, and renal function and blood sugar were normal. As patient did not have signs such as fever or leukocytosis, infectious processes were thought to be less likely. Differentials most highly considered were: rheumatoid nodulosis, calciphylaxis, and vasculitis. Dermatology was consulted. Skin biopsies from right upper arm and left medial thigh lesions were performed. The patient was discharged home prior in stable condition, instructed to follow up with her rheumatologist in a few weeks. She was told to not to take her calcium supplement, prednisone, or MTX for the time being. Pathology report states that granulomatous inflammation throughout the dermis and panniculus was seen. Pathologist's comment stated that this was most likely granulomatous vasculitis associated with RA. The patient's rheumatologist concluded that the patient's areas of induration were likely due to underlying vasculitis, and the nodular lesions most likely represented methotrexate-induced accelerated nodulosis (MIAN). The patient's methotrexate was held, and upon 1-month follow-up, she reported complete resolution of all skin lesions (with the exception of a small scar in the left medial thigh where the most advanced lesion had been).

DISCUSSION: Our patient's lesions were ultimately felt to be methotrexate-induced accelerated nodulosis (MIAN) along with rheumatoid vasculitis. This case highlights the differential diagnosis of erythematous and nodular skin lesions in a patient with rheumatoid arthritis. The first thing to rule out was calciphylaxis, due to its high potential for mortality. Calciphylaxis has occurred in patients on immunosuppressant medications and those with vasculitis, such as our patient, but it is much more commonly seen in patients with end-stage renal disease. Furthermore, our patient's calcium phosphate product (CPP) was not greater than 70, which is usually seen with calciphylaxis. Furthermore, the patient's upper extremities were involved, which is rare in calciphylaxis. Finally, the skin biopsy failed to show intravascular calcium deposition in the dermal media, thus ruling out this deadly condition. MTX is postulated to accelerate rheumatoid nodule formation (hence the term MIAN) by stimulation of adenosine A1 receptors, which leads to increased giant cell formation. Differentiating between usual rheumatoid nodules and MIAN is important, as management differs for these two conditions. The histopathology of the two cannot be easily differentiated. Some factors that point towards MIAN are: nearly all patients with MIAN are seropositive for RF, and 25 % have a concurrent vasculitis. Furthermore, lesions on atypical sites such as finger tendons, smaller (less than 5 mm) lesions, rapid development of lesions, and absence of extra-articular involvement point towards MIAN, with most patients having been on methotrexate for at least 3 months.

SKIN RASH, IS IT AN INFECTION? Mahmoud Abdelghany; Samuel Massoud. Conemaugh Memorial Medical Center, Johnstown, PA. (*Tracking ID #1922858*)

LEARNING OBJECTIVE 1: – Eruptive xanthoma is a cutaneous disease results from hypertriglyceridemia and poorly controlled diabetes.

LEARNING OBJECTIVE 2: – Early recognition of eruptive xanthoma is crucial to avoid more serious sequelae including acute pancreatitis and ophthalmic complications.

CASE: A 50 -year-old obese man with a past history of hypertension, hyperlipidemia and recently diagnosed diabetes presented complaining of skin rash for 1 week. He denied any history of fever, chills, myalgia, abdominal pain, visual changes, history of new drug use or contact with anyone with similar symptoms. His medications included lisinopril, simvastatin, niacin, metformin. On physical examination, the lesions were small reddish yellow non-pruritic tender papules covering the extensor surfaces of knees, forearms,

the abdomen and the back. Laboratory evaluation showed total cholesterol level 1045 mg/dl, triglyceride level 7855 mg/dl, TSH 0.52 uIU/ML, fasting blood glucose 441 mg/dl and HbA1c 12.6 %. Three months before the laboratory evaluation showed total cholesterol 163 mg/dl, triglyceride level 614 mg/dl, fasting blood glucose 158 mg/dl and HbA1c 7.5 % and the patient was first diagnosed with diabetes mellitus. Histologic analysis of a lesion-biopsy specimen showed foamy macrophages and loose lipids, which confirmed the suspicion of eruptive xanthomas. Immediately after the diagnosis, the patient was started on a strict glycemic and lipid control. Metformin and statin doses were increased and insulin was added. Three weeks later there was marked improvement of the skin lesions.

DISCUSSION: Eruptive xanthoma is a cutaneous disease that most commonly arise over the extensor surfaces of the extremities, buttocks and shoulders. High levels of serum triglycerides and uncontrolled diabetes mellitus could be the cause. Hypothyroidism, end-stage renal disease and nephrotic syndrome can cause secondary hypertriglyceridemia. This condition may be associated with ophthalmologic deposition of cholesterol, such as lipemia retinalis (salmon-colored retina with creamy white retinal vessels), abdominal pain, and hepatosplenomegaly. Treatment involves dietary restrictions, exercise and medical management. Insulin, statin and gemfibrozil may be necessary for rapid control of the diabetes and hyperlipidemia. Early recognition and proper control of hypertriglyceridemia can prevent more serious complications as acute pancreatitis.

SPINE MRI AS WORK UP FOR SORE THROAT: A CASE OF MISSED PHARYNGITIS LEADING TO THE DIAGNOSIS OF ACUTE RHEUMATIC CARDITIS Lauren Mehner¹; Melissa Reidy¹; Luke Peters¹; Daniel Chan²; Maria G. Frank³. ¹University of Colorado, Aurora, CO; ²University of South Dakota, Sioux Falls, SD; ³Denver Health Hospital Authority, Denver, CO. (*Tracking ID #1922217*)

LEARNING OBJECTIVE 1: To raise awareness over the low but definite incidence of acute rheumatic fever (ARF)

LEARNING OBJECTIVE 2: To describe a case of ARF presenting with carditis and polyarthralgias

CASE: Thirty-five year-old female with no significant medical history presented to the ED complaining of 1 week of odynophagia, malaise, polyarthralgias, fever, back pain and headaches. Because she received epidural anesthesia for a vaginal delivery 1.5 months prior, she was evaluated with a spine MRI, which was unremarkable, and was discharged home with symptomatic treatment for back pain. She returned to the hospital 2.5 weeks later complaining of persistent polyarthralgias with additional large joint involvement, malaise, and subjective fever and was admitted to the medicine wards for further work-up. Her exam was significant for a new systolic murmur, best heard in the mitral area, and polyarthritis without synovitis. Her laboratory tests revealed ASO of 491 with ESR above 80 and CRP of 73.90. Bilateral hand X-rays were normal. A Trans-Thoracic Echocardiogram (TTE) showed severe Mitral Regurgitation and moderate Aortic Regurgitation. Because she met 2 major and 2 minor Jones criteria plus the evidence of a preceding Group A beta-hemolytic Streptococcus infection (GABHS), she was diagnosed with ARF. She was started on Penicillin G with a plan to receive monthly doses for a total of 10 years, as well as biannual TTE.

DISCUSSION: Acute rheumatic fever (ARF) has not been a reportable disease in the US since 1977 and ever since its diagnosis has been anecdotal. The advent of antibiotics, early diagnosis and treatment with rapid strep tests and cultures, as well as the described changes in streptococcal M proteins have led to a near disappearance of this malady in the developing world. ARF is a preventable disease; in fact, several studies on the treatment of GABHS pharyngitis to prevent ARF concluded that there would be a reduction in ARF cases by as much as 60 % if pharyngitis was appropriately treated, especially in endemic areas. While ARF remains high on the differential among immigrant populations and when practicing in endemic countries, this case serves as a reminder to remain vigilant in the U.S. as well. Common reasons for missed diagnosis and treatment failure among providers include absence of clinically significant preceding pharyngitis, anchoring biases, and failure to include ARF in the differential due to the extremely low disease incidence in the U.S. Additionally, patient factors such as failure to seek care for pharyngitis and poor antibiotic compliance contribute to the persistence of ARF. Because of the high risk of recurrence upon re-exposure to GABHS, it is essential that providers correctly diagnose ARF and begin patients on secondary prophylaxis. Our case demonstrates the need to raise awareness in the medical community around this infrequent condition as well as the need to be cognizant of our personal clinical biases.

SPONTANEOUS RENAL SUBCAPSULAR HEMORRHAGE AS A POSSIBLE COMPLICATION OF EXTERNAL RADIOTHERAPY Tarun Jain; Suraj Raheja. Henry Ford Hospital, Detroit, MI. (*Tracking ID #1939661*)

LEARNING OBJECTIVE 1: Recognize the common and uncommon causes of spontaneous renal subcapsular hemorrhage.

CASE: Spontaneous subcapsular renal hemorrhage is a severe condition that leads to the abrupt removal of a kidney in two-thirds of cases. The primary causes described in the literature include renal tumors, vascular disease, and infections. We present a rare case of spontaneous subcapsular renal hemorrhage in the absence of these common causes, and as an apparent complication of radiation therapy used for the treatment of prostate cancer. We present an 84 year old male with past medical history of prostate cancer T2bN0M0 treated definitively with hormones and external radiation therapy 10 years ago. He presents with a 2 day history of sudden onset left sided lower abdominal pain. The patient denied hematuria, dysuria, lower urinary tract symptoms, hematuria, history of nephrolithiasis or history of UTIs. As part of his workup, abdominal computed tomography (CT) was performed, which demonstrated left hydronephrosis with obstruction at the left ureteropelvic junction. The left kidney was also noted to have very thin parenchyma. Urology was consulted and noted that the obstruction may be a result of his previous radiation therapy, but because his PSA was stable there was no immediate urologic surgical intervention. He was discharged with analgesics and arranged for outpatient Urology follow-up. The patient, however, returned 1 week after this initial presentation, with complaints of persistent pain not alleviated by analgesics. Review of systems on this second presentation was negative for fever, nausea, vomiting, dysuria, frequency, urgency or hematuria. On physical exam, there was suprapubic fullness along with left lower quadrant and suprapubic tenderness. The patient's creatinine was elevated to 3.5 mg/dl from a baseline of 1.5 mg/dl, but he had no elevation in his leukocyte count and his hemoglobin was not significantly decreased from his previous presentation. Repeat abdomen-pelvis CT scanning now demonstrated a new spontaneous hemorrhage in the subcapsular space of the left kidney, extending into the dilated intra-renal collecting system, along with worsening hydronephrosis. Urology initially debated between ureteral stent with nephrostomy versus nephrectomy, but it was ultimately decided to manage the patient conservatively.

DISCUSSION: A meta-analysis of subcapsular and peri-renal hemorrhages reported tumors as the etiology in over 61 % of cases. Vascular diseases, including polyarteritis nodosa, aneurysms and arterio-venous malformations, were a collective 17 % of cases. Infectious etiologies of abscess and pyelonephritis totaled 2.4 % of cases. No cause was identified or reported in approximately 7 % of cases, with the remaining 13 % being attributed to miscellaneous causes. These included uncontrolled hypertension, cyst rupture, nephrosclerosis and pre-eclampsia. Except for the exposure to radiation therapy, no particular cause for spontaneous hemorrhage could be identified in this patient. Physicians routinely encounter renal tumors, vascular diseases and infections of the renal system. Related to these common findings, this case renews the awareness of sub-capsular or peri-renal hemorrhage, and the need to assess these patients knowing the frequency of abrupt nephrectomy as a treatment outcome. In addition, physicians should be able to integrate the less commonly encountered causes that have been highlighted. Our case suggests radiation therapy as an additional risk factor for this hemorrhagic event.

SPONTANEOUS TUMOR LYSIS SYNDROME DUE TO NEUROENDOCRINE TUMOR Waleed Quwatli; Charu Ramchandani; Mahesh Krishnamurthy. Unity Health System, Rochester, NY. (*Tracking ID #1939411*)

LEARNING OBJECTIVE 1: Spontaneous tumor lysis syndrome (TLS) due to non-hematologic malignancy is rare but it is very crucial to be recognized and treated promptly.

CASE: A 60 year old male who was referred to the emergency room by a gastroenterologist for progressive abdominal pain and rapidly growing hepatomegaly for 1 month associated with worsening liver and renal functions. Review of system was positive for nausea, vomiting, diarrhea, anorexia, weight loss, weakness, jaundice, shortness of breath and oliguria. His past medical history was significant for Ankylosing spondylitis treated with Adalimumab and Methotrexate both of which were discontinued few months prior to presentation due to transaminitis and elevated creatinine. On physical examination he was hypotensive, tachypneic, tachycardic, mild icteric jaundice, flushed face. Lung exam showed bibasilar crackles with mild diffuse wheezing, heart was with normal sounds, abdomen exam showed massive hepatomegaly without stigmata of chronic liver disease. His lab tests showed BUN 66 mg/dL, Creatinine 4.8 mg/dL (baseline 1.4 mg/dL), potassium 4.9 mEq/L, phosphorus 5.3 mg/dL, uric acid 26.1 mg/dL, ALT 63 uL, AST 284 uL, total bilirubin 2.7 mg/dL, direct bilirubin 2.2 mg/dL, LDH 1292 uL. Computed Tomography of the abdomen

without contrast showed heterogeneous hepatomegaly with irregular contour. Based on the laboratory tests and the rapidly growing hepatomegaly there was a high suspicion of spontaneous tumor lysis syndrome. The patient developed non sustained ventricular tachycardia for that he was transferred to the ICU where dialysis was initiated, Rasburicase was given intravenously. Magnetic resonance imaging of the abdomen showed innumerable lesions throughout the liver. Biopsy showed well differentiated neuroendocrine tumor. Repeated Uric acid level was <1 mg/dL. The patient refused chemotherapy and further work up to identify the primary origin. He deteriorated rapidly, developed multi-organ failure and passed away.

DISCUSSION: Tumor lysis syndrome (TLS) is an oncologic emergency that is caused by massive tumor cell lysis and release of large amounts of potassium, phosphate, and uric acid into the systemic circulation leading to hyperuricemia, hyperkalemia, hyperphosphatemia, and secondary hypocalcemia. This can lead to significant morbidity, putting patients at risk of severe clinical consequences that include acute kidney injury, cardiac arrhythmias, pulmonary edema, fluid overload, seizures, and even death. Laboratory TLS is defined as any two or more of the following metabolic abnormalities and presents within 3 days before or 7 days after instituting chemotherapy: hyperuricemia, hyperkalemia, hyperphosphatemia, and hypocalcemia. Clinical TLS is defined as laboratory TLS plus one or more of the following that was not directly or probably attributable to a therapeutic agent: increased serum creatinine concentration (≥ 1.5 times the upper normal limit), cardiac arrhythmia/sudden death, or a seizure. TLS is associated most commonly with initiation of aggressive chemotherapy for hematologic malignancies like non-Hodgkin lymphomas and acute lymphoblastic leukemia. Spontaneous TLS is not commonly seen and just few cases of spontaneous TLS due to neuroendocrine tumor (NET) have been reported in literature. Spontaneous acute renal failure associated with marked hyperuricemia prior to the initiation of therapy has been described in lymphomas and acute leukemias. It usually occurs in patients with bulky, rapidly proliferating, treatment-responsive tumors. Interestingly, spontaneous TLS is associated with hyperuricemia but frequently without hyperphosphatemia because the high serum uric acid levels are related to rapid nucleoprotein turnover and the tumor is able to reutilize released phosphorus for resynthesis of new tumor cells. Effective management involves the combination of treating specific electrolyte abnormalities, and/or acute renal failure, and the use of allopurinol, a xanthine oxidase inhibitor administered to reduce the conversion of nucleic acid byproducts to uric acid in order to prevent urate nephropathy and subsequent oliguric renal failure. Rasburicase is a recombinant urate oxidase responsible for the oxidation of uric acid to allantoin which is more soluble in urine than uric acid and because of its rapid onset of action, it is indicated when uric acid levels cannot be lowered sufficiently by standard approaches. A loop diuretic and intravenous fluids is frequently needed, and hemodialysis may be indicated if the patient developed severe oliguria/anuria, persistent hyperkalemia, or hyperphosphatemia induced symptomatic hypocalcaemia. Spontaneous TLS due to NET is extremely rare, and spontaneous TLS by itself is an oncologic emergency which should be included in the differential diagnosis of patients with rapidly growing tumors who present with acute kidney injury even if they did not receive chemotherapy.

STAPHYLOCOCCUS LUGDUNENSIS: THE GREAT CONS ARTIST Julie M. Collins; Chad S. Miller. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1926986*)

LEARNING OBJECTIVE 1: Demonstrate the pathogenicity of coagulase-negative staphylococcus.

LEARNING OBJECTIVE 2: Review the clinical presentation of infective endocarditis.

CASE: A 49-year-old woman with HIV (CD4 count 101 cells/uL) and end stage renal disease presented with 9 days of progressive shortness of breath after a revision of her arteriovenous (AV) fistula for dialysis. She also noted generalized fatigue, subjective fever, four-pillow orthopnea and new-onset paroxysmal nocturnal dyspnea. Her temperature was 99.2 °F, blood pressure 132/74, respirations 16, and saturation 99 % on room air. She had a 3/6 systolic ejection murmur noted at previous admissions as well as a new regurgitant murmur loudest in the mitral position, jugular venous distention, and 1+ lower extremity pitting edema. There was no erythema surrounding her right upper extremity AV fistula. WBC count was 14.2×10^3 /uL with left shift. On day 2, she developed a fever to 101.6 °F. Blood cultures from two sites grew coagulase-negative staphylococcus and repeat cultures were drawn. Blood cultures remained persistently positive for Staphylococcus lugdunensis for 8 days. A transthoracic echocardiogram (TTE) with bubble study showed an ejection fraction of 55–60 %, no shunt, and a vegetation on the atrial aspect of the

anterior mitral leaflet. She was treated with nafcillin while inpatient and then transitioned to 6 weeks of cefazolin with dialysis.

DISCUSSION: Internists commonly encounter heart murmurs, and their etiology can be either benign or pathogenic. A high degree of suspicion for infective endocarditis (IE) with a new or changed heart murmur is imperative because endocarditis can rapidly cause irreversible damage to the heart. IE in chronic hemodialysis patients is significantly more common and causes greater morbidity and mortality than in the general population, being second only to cardiovascular disease as the leading cause of death in this group. *Staphylococcus lugdunensis* is a coagulase-negative staphylococcus (CONS) that like other CONS infections can range from a harmless skin flora to a life-threatening pathogen. *S. lugdunensis* affects native valves with greater frequency than prosthetic valves, unlike other CONS. IE due to this organism is characterized by a high mortality and rapid tissue destruction. Often, hospital laboratories will report non-aureus isolates only as CONS, but speciation of the organism can assume great importance in defining therapeutic approach. For example, the clinical outcome in the treatment of *S. lugdunensis* is much more favorable with valvular replacement than with antibiotics alone. Despite their frequency as contaminants, CONS have become important nosocomial pathogens, accounting for 9 % of all nosocomial infections. CONS are also the third most common cause of blood stream infections. The incidence of CONS bacteremia in patients with foreign bodies such as a port is increased compared to the general population due to their strong adherence to polymer surfaces and biofilm formation. It is important to assess the clinical picture when faced with CONS-positive blood cultures because these organisms are not always contaminants, and can cause significant morbidity and mortality when not treated appropriately.

STEAK IT'S WHAT'S FOR DINNER Elizabeth Bowles; Molly Doose. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1924659*)

LEARNING OBJECTIVE 1: Consider acquired bronchoesophageal fistula in acquired immunodeficiency syndrome patients presenting with aspiration pneumonia in an atypical location.

LEARNING OBJECTIVE 2: Recognize populations at risk for acquired bronchoesophageal fistula and the importance of timely intervention.

CASE: A 50 year-old man with acquired immunodeficiency syndrome presented with 2 months of worsening cough, shortness of breath, and fever. He described a forceful cough associated with solid food or liquid intake and subsequent emesis, with a fifty-pound weight loss over the preceding 4 months. Upon examination, the patient was noted to be cachectic, with tachypnea and hypoxemia that responded well to oxygen supplementation via nasal cannula. No abnormal breath sounds were auscultated. Chest radiograph had no acute findings; however cough after oral intake prompted a modified barium swallow and chest computed tomography to evaluate further for aspiration. Modified barium swallow revealed no frank aspiration. Computed tomography revealed a left lower lobe consolidation with bronchiectasis, cavitation, air fluid levels, and punctate calcifications. Failure of response to typical therapy prompted bronchoscopy, which revealed vegetable matter with skeletal muscle fibers on biopsy of the consolidation. On esophagogram, contrast extravasation into the medial left lower lobe was consistent with a fistula. Esophagogastroduodenoscopy confirmed a 3 cm long false lumen in the esophagus, about 34 cm from the entry site, with esophageal mucosa on one side and bronchial tissue on the other. At the distal aspect of the lumen, there was a small opening, representing a discrete fistulous tract entering the lung.

DISCUSSION: In patients with known acquired immunodeficiency syndrome presenting with respiratory distress, infectious etiology including pneumocystis pneumonia, tuberculosis, viral, or bacterial pneumonia should be considered, with empiric therapy initiated quickly. When a patient's symptoms persist despite appropriate therapy, further workup must be considered. Though rare, bronchoesophageal fistulas have been reported in acquired immunodeficiency syndrome patients, presenting with progressive dysphagia, weight loss and episodes of cough on intake of food. Imaging findings consistent with aspiration pneumonia should prompt continued workup for a fistula. Diagnosis can be made by barium esophagogram, with location and size of the fistula determined by bronchoscopy or esophagogastroduodenoscopy. Other patient populations at risk for acquired esophago-airway fistulas include patients who have undergone tracheal intubation, ingested corrosives, sustained chest trauma or iatrogenic injury, suffered granulomatous mediastinal infections, had prior surgery on the esophagus or tracheobronchial tree, or those with indwelling stents. In patients presenting with an esophago-airway fistula without one of the above risk factors, malignancy, especially esophageal carcinoma, must be considered. Therapies for an esophago-airway fistula include esophageal stenting, esophageal exclusion, esophageal bypass, and fistula resection and repair. Insertion of a coated self-expandable metal stent is the treatment of choice

for an individual with malignant esophago-airway fistula. Without treatment, the median survival time may be 1 to 6 weeks, with aspiration pneumonia as the usual cause of death.

STEMI, ELEVATED PTT AND ANEMIA: A LIFE THREATENING SYNDROME Zakaria Almuwaqqat, saint francis hospital, Evanston, IL. (*Tracking ID #1939026*)

LEARNING OBJECTIVE 1: – Early diagnosis of antiphospholipid syndrome in a previously healthy young patient presenting with chest pain and elevated PTT.

LEARNING OBJECTIVE 2: – Importance of early anticoagulation therapy to prevent recurrent myocardial and cerebral infarction as well as failure of coronary intervention. - recognition of one of the cardiac manifestations of antiphospholipid syndrome.

CASE: 30 year old African American male patient presented to the emergency department with intermittent chest pain for 4 days associated with diaphoresis, arm numbness and tingling, palpitations. Patients reported that he would eat, smoke a cigarette, then get these symptoms; resolved within 4–5 min. patient described chest pain as “grabbing” pain, 10/10 retrosternal radiating to the arm. Episodes were becoming more frequent. Took 500 mg of tylenol twice without relief. Past medical history is significant for vitamin B12 deficiency. Patient admitted to smoking history of 1 ppd for the past 10 years. Patient had no recent travel. Denies any personal or family history of blood clots, DVT, cardiac disease, stroke or DM. Patient has history of pernicious anemia, has not been getting his B12 Injection. Family history was negative for coronary artery disease, thrombophilia and hyperlipidemia His physical examination: Alert, oriented ×3, not in distress, neck no jugular venous distention, chest clear no rales, heart regular rate and rhythm, no murmur or gallops, abdomen soft, non-tender and non distended, extremities warm and without edema. EKG revealed Normal sinus rhythm with anterolateral ST segment depression, labs showed elevated troponin, Hemoglobin 14.1, MCV 93, WBC 4.5, Plt 260, Cr 0.76, BUN 8, INR 1.1, PTT 200. Patient had chest CT to rule out aortic dissection revealing possible stenosis of LAD coronary artery, patient subsequently underwent cardiac angiogram which showed subtotal ostial LAD stenosis with thrombus possibly due to ulcerated plaque had successful thrombectomy with aspiration catheter and residual lesion less than 40 %, patient due to proximity of LAD stenosis to left main patient was referred for medical treatment and repeat of stress test in 4 weeks to evaluate hemodynamic significance of the lesion and if needed consider high risk PCI or single vessel CABG Patient was admitted to intensive care unit and chest pain resolved completely, however in the second day he started to complain from recurrent severe chest pain, EKG showed new ST elevation in anterolateral leads, emergency cardiac angiogram with drug letting stent inserted in proximal LAD.

DISCUSSION: Patient had work up for premature coronary artery disease and hypercoagulable state, his PTT was 200, lupus anticoagulant work up was positive for lupus antibodies, his intrinsic factor blocking antibody was also positive, ANA was negative and complement levels were normal, his vitamin B12 level was low and homocysteine was elevated, patient was diagnosed with antiphospholipid syndrome and started on therapeutic dose low molecular weight heparin and warfarin subsequently. Antiphospholipid syndrome is an autoimmune disease characterized by venous and/or arterial thrombosis and/or recurrent fetal loss and the presence of antiphospholipid antibodies. The case illustrates one of the cardiac manifestations of antiphospholipid syndrome, its an important and potentially treatable cause of myocardial and cerebral infarction, its also a recognized cause of sudden death and failure of coronary intervention during myocardial infarction treatment, other manifestations includes ventricular thrombosis, pulmonary embolism, arterial thrombosis, pregnancy losses, recurrent coronary events and valvular heart disease which is based on the presence of thickening or vegetation of the valves (mainly mitral and aortic) as described by Libman and Sacks for patients with systemic lupus erythematosus (SLE).

STERILE PYURIA - A CLASSIC TALE WITH A MODERN TWIST Celeste Newby; Krystle Baraghgi; Marlowe Maylin. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1925002*)

LEARNING OBJECTIVE 1: Identify the clinical presentation and methods for detection of genitourinary tuberculosis

LEARNING OBJECTIVE 2: Discuss the differential diagnosis for sterile pyuria in modern medicine

CASE: A 51 year-old man with no past medical history presented with subjective fevers and weight loss for 1 month; review of systems was otherwise negative. A palpable supraclavicular lymph node was the only abnormal finding on physical

exam. The patient's chest radiograph was normal. Urinalysis on admission was negative for nitrites and bacteria, but positive for leukocyte esterase. The patient was intermittently febrile to $>39^{\circ}$ Celsius during admission, but multiple blood and urine cultures were negative. The patient complained of dysuria on day 3. A repeat urinalysis showed large leukocyte esterase, but urine cultures remained negative. CT scans were notable for diffuse abdominal lymphadenopathy and wedge-shaped deformities of both kidneys. The patient underwent excisional lymph node biopsy secondary to concern for lymphoma. The tissue was Fite stain positive for mycobacterial species. On further discussion, the patient admitted being diagnosed with HIV 20 years ago, but never sought medication attention. Acid-fast bacilli (AFB) cultures from the urine were positive for mycobacterium tuberculosis several weeks later.

DISCUSSION: In the past, sterile pyuria suggested the presence of genitourinary tuberculosis (GU-TB). GU-TB is seen in approximately 30 % of extra-pulmonary tuberculosis cases and is usually the result of dissemination from pulmonary disease. Patients with GU-TB rarely exhibit lung disease or respiratory symptoms. Extra-pulmonary TB has a higher prevalence in the setting of immunosuppression such as in HIV or organ transplant recipients. GU-TB is difficult to recognize, as bacterial urine culture media are less favorable for mycobacterial growth and may not provide a high yield. AFB urine culture has a 37 %–79 % sensitivity and is the gold standard in diagnosis of GU-TB. Multiple urine samples can increase sensitivity, and some suggest early morning samples are best. AFB cultures, however, can take up to 8 weeks to result. Newer PCR techniques have variable sensitivity (25–93 %) with high specificity (95–100 %) but currently are not widely available. While symptoms of a urinary tract infection coupled with pyuria and negative bacterial growth can suggest GU-TB in the appropriate clinical setting, it is important for internists to note that sterile pyuria has a larger differential diagnosis. In an era of widespread antibiotic use, the most likely result of sterile pyuria is recent or incomplete antibiotic use rather than tuberculosis. Negative urine cultures can also be seen with atypical infections such as Chlamydia and Ureaplasma species, and can also be seen in autoimmune disease, prostatitis, nephrolithiasis, and malignancy. In most cases of sterile pyuria, a thorough review of medication and sexual history can provide the diagnosis.

STEROIDS AND WORMS: DIAGNOSING A RARE CAUSE OF ABDOMINAL PAIN IN ADVANCED AIDS Nihal Patel; Olga Aroniadis; Sheira Schlair. Albert Einstein College of Medicine - Montefiore Medical Center, Bronx, NY. (*Tracking ID #1934583*)

LEARNING OBJECTIVE 1: Identify the use of corticosteroids as a risk factor for developing *Strongyloides stercoralis* (SS) hyperinfection syndrome

LEARNING OBJECTIVE 2: Recognize the rare presentation of SS hyperinfection syndrome in advanced AIDS patients

CASE: A 44 year-old Puerto Rican man with long-standing poorly controlled HIV/AIDS (CD4=34 cells/mm³), a history of *Pneumocystis jirovecii* pneumonia (PCP) and moderate persistent asthma presented to the hospital with 2 weeks of progressively worsening exertional dyspnea and a productive cough. Recurrent PCP was suspected due to marked hypoxemia, and he was started on empiric trimethoprim-sulfamethoxazole (TMP/SMX) and corticosteroids. Several hours later he developed a high-grade fever ($>104.0^{\circ}$ F), increased dyspnea, wheezing, sharp constant epigastric pain, loose stools, nausea and a serpiginous rash on his proximal thighs and buttocks. Initially, a drug reaction to the administered TMP/SMX was presumed, however his abdominal complaints remained unexplained. Blood work revealed a white blood cell count of 3400/ μ l with eosinophilia (37 %). An abdominal CT scan did not indicate any acute pathology and stool studies for ova and parasites were negative. On further questioning, the patient reported chronic abdominal pain and several episodes of acutely worsened pain associated with dyspnea, loose stools and anorexia with each episode occurring after corticosteroid administration. SS hyperinfection was suspected in light of this history and serum testing for SS IgG was performed, which was positive. The patient was treated with a course of ivermectin for 2 weeks and his symptoms resolved, confirming SS hyperinfection syndrome.

DISCUSSION: Immunocompetent patients infected with SS are often asymptomatic. Some patients may have vague waxing and waning gastrointestinal, cutaneous or pulmonary symptoms; and blood tests in chronically infected patients commonly indicate eosinophilia. Diagnosis can be achieved via stool microscopy for ova and parasites although this test has a low sensitivity due to intermittent larval excretion in stool. ELISA testing to detect IgG is considered superior with a high sensitivity (83–89 %) and specificity (97 %) based on commercial assays. SS hyperinfection syndrome occurs when chronically infected patients with SS become immunosuppressed, resulting in an uncontrolled over-proliferation of larvae within organs involved in autoinfection such as the lungs and GI tract. The use of corticosteroids, which results in the impairment of cell mediated immunity, is the strongest risk factor

for developing this syndrome. Classic manifestations of the hyperinfection syndrome include fever, nausea, vomiting, diarrhea, anorexia, abdominal pain, dyspnea, wheezing and/or cough, as in this patient's case. Chest radiographs can indicate pulmonary infiltrates; and following hyperinfection, gram negative septicemia secondary to the translocation of gut flora may also occur. Surprisingly, this syndrome in severely immunocompromised patients with advanced HIV/AIDS is rare, with few cases reported to date. It might be expected that HIV/AIDS patients who are lacking cell mediated immunity are predisposed to SS hyperinfection. This is not the case however, since HIV-infected patients typically have a loss of Th1 immune activity but preserved Th2 activity. These changes, particularly the preservation of Th2 activity, have been proposed to play a role in preventing hyperinfection and the dissemination of SS. Treatment with steroids nonetheless can trigger an SS hyperinfection syndrome. This case highlights the vigilance required when contemplating corticosteroid administration in HIV positive patients with depressed CD4 counts, especially when SS may be suspected.

STEVEN JOHNSON SYNDROME Ahmed Abuzaid; Khaled M. Aboulezz; Mohamed El khashab. Creighton university medical center, Omaha, NE. (*Tracking ID #1940193*)

LEARNING OBJECTIVE 1: Recognize causes of Steven Johnson Syndrome.

LEARNING OBJECTIVE 2: Recognize proper management of Steven Johnson Syndrome

CASE: A 74-year-old male with past medical history of hypertension and gout that was started on allopurinol 2 months before admission. He presented with fatigue, progressive generalized skin lesions which started suddenly 2 weeks before the admission, all over his body, involving his hands and feet, associated with odynophagia and eye redness. On examination, Blood pressure 152/75, temperature 99.0, respiratory rate 19, heart rate 70. Skin showed red macules, papules and patches all over his body. Also he had multiple superficial ulcers involving his face, chest and arms with positive nikolsky sign. Eye examination showed bilateral conjunctival erythema. Blood test showed bicarbonate 21 mmol/l, creatinine 1.6 mg/dl, BUN 31 mg/dl, glucose 189, WBC 6.1 K/ μ L. Patient was admitted for close observation, allopurinol was stopped. He was given IV fluid, feeding tube was placed because of severe odynophagia and punch biopsy was done. Punch biopsy showed interface bullous dermatitis with necrotic keratinocytes, consistent with early phases of Steven Johnson syndrome. Patient developed more ulceration in his face, chest and arm, almost 15 % of his body surface area and multiple bullae. Blood culture showed gram negative rods. Patient was started on IV antibiotics and transferred to burn unit for further management.

DISCUSSION: Our patient developed Steven Johnson syndrome mostly secondary to allopurinol. This is a rare and severe disease that affects skin and mucous membrane with necrosis and sloughing of the epidermis in a reaction to medication or infection. Most common medications are allopurinol, sulfonamides, carbamazepine and phenobarbital. It presented usually with fever and influenza-like symptoms then maculopapular lesions which progress to vesicular and bullous skin lesions followed by sloughing. The most important step in the management is discontinuing the offending medicine and supportive treatment. Close observation is needed to avoid serious complication like dehydration and sepsis, usually symptoms resolve within 4–6 weeks. No definite data about using steroids or IVIG as supportive therapy. Prognosis of the disease is determined usually by using the SCORTEN score, which calculated according to the patient age, history of malignancy, tachycardia, percentage of detached skin and levels of HCO₃, glucose and urea level. Patient with high score should be treated at specialized unit. Our patient was transferred to a burn unit after his lesions get worse and the detached area of skin was more than 15 % of body surface area. Patient should wear a bracelet to identify the offending medicine. Conclusion: Steven Johnson syndrome is a serious mucocutaneous disease results from a reaction to medicine or disease. It can be life threatening condition. The cornerstone in management is discontinuing the offending medicine and supportive treatment in a specialized unit if severe.

STEVEN JOHNSON SYNDROME FROM ERTAPELEM: A UNIQUE CASE REPORT Karthik Ragunathan¹; David Slagle². ¹OSF St. Francis medical center, peoria, IL; ²OSF St. Francis medical center, peoria, IL. (*Tracking ID #1923710*)

LEARNING OBJECTIVE 1: Recognize the need to avoid all beta lactam containing antibiotics in a patient with previous Steven Johnson Syndrome (SJS) to any beta lactam antibiotic

CASE: 75 year old asian male with past history of IgG kappa multiple myeloma, thrombocytopenia, stroke, chronic kidney disease presented to the ED with

complaints of non-traumatic fall. He also had history of fever, chills, foul smelling urine and confusion for 1 day. Review of systems was significant for chronic weakness and reduced appetite. Examination showed diffuse petechial rash in face, legs Initial labs showed WBC of 2.5 with absolute neutrophil count of 440, Hb of 7.3, platelets of 30. CMP showed creatinine of 3.79 (baseline 1.8). Urine analysis showed 50–200 WBC, esterase 2+, nitrite and bacteria positive. Initial procalcitonin was 46.55 which increased to 107.42 in 3 days. Chest Xray did not show any opacity. Nasal MRSA screen was positive and HIV ELISA was negative. Initial concern was for neutropenic fever from urinary tract infection in an immunocompromised patient. He has had previous SJS reaction to ampicillin and was also allergic to penicillin causing hives. He was given one dose of Ertapenem and Vancomycin. He developed a new skin rash the following day and was diffusely erythematous throughout the body. Both the antibiotics were stopped due to concern for SJS and gentamycin was started. Initial urine culture was positive for *E. Coli* resistant to cefotaxime and levofloxacin but subsequent urine cultures were negative. Clinical course was complicated because of obtundation, decerebrate posture requiring intubation and ventilator support. CT, MRI of brain was negative. His clinical status did not improve with continuing fevers, skin rash desquamating to purplish patches in few regions of body, facial swelling and he eventually deceased after comfort care was chosen by his power of attorney.

DISCUSSION: To our best of knowledge, this is the first reported case of SJS secondary to Ertapenem exposure. Previous studies have reported mixed results for allergic reactions from cross reactivity between penicillin and carbapenem class of drugs [2–4]. Two studies showed incidence of patients with a reported or documented penicillin allergy experiencing an allergic-type reaction to a carbapenem was 11% [2] and 9.2% [3] although it does not quantify the exact types of allergic reaction. Other study reported that it is safe to use meropenem in patients with history of allergic reactions to penicillin [4]. One previous case report reported toxic epidermal necrolysis (TEN) to meropenem in a patient with documented TEN to cefotaxime [5]. SJS occurs in 1–2 cases per million person years [1]. Common drugs causing SJS include allopurinol, antibiotics (Sulphonamides, penicillins and cephalosporins), carbamazepine, lamotrigine. Risk factors for SJS are HIV, immunologic diseases (multiple myeloma in my patient), viral infections. Typical presentation is a prodrome of fever followed by erythroderma, facial edema, mucosal erosions and bleeding. Although skin biopsy can be used to confirm the condition, clinical diagnosis in the setting of trigger factor is mostly used for diagnosis. Differential diagnoses include erythema multiforme, erythroderma, toxic shock syndrome, staphylococcal scalded skin syndrome. Definitive treatment is to stop the offending drug and give supportive wound care, fluid replacement, and sterile environment along with therapies such as systemic corticosteroids, intravenous immunoglobulin and cyclosporine. Overall mortality is 10% with sepsis, acute respiratory distress syndrome and multi-organ failure as the most common etiologies. The main objective of our clinical observation is to emphasize the need to avoid all beta lactam containing antibiotics in a patient with documented severe hypersensitivity reactions such as SJS, TEN to any beta lactam antibiotic. We also emphasize the need for proper documentation of allergic reactions to drugs to avoid errors by documenting pseudo-allergies. Reference 1. The current understanding of Stevens-Johnson syndrome and toxic epidermal necrolysis : Expert Rev Clin Immunol. 2011 Nov;7(6):803–13; quiz 814–5. doi: 10.1586/eci.11.66 2. STEVENS - JOHNSON SYNDROME: AN UNUSUAL ADVERSE REACTION TO AZITHROMYCIN Runa Shrestha¹; Rajesh Mourya²; Ramsay Farah¹. ¹SUNY Upstate Medical University, Syracuse, NY; ²Creighton University, Omaha, NE. (Tracking ID #1932843)

LEARNING OBJECTIVE 1: Stevens - Johnson syndrome (SJS) is a rare, life threatening, idiosyncratic reaction characterized by fever and mucocutaneous lesions causing epidermal necrosis and sloughing. Medications and infections are the two most common causes of SJS. Here we present an interesting case in which SJS was seen as an unusual adverse reaction to a commonly used antibiotic.

CASE: A 19-year-old, healthy, African-American male, presented to the emergency department with a 3 day history of fever, chills, fatigue followed by painful mucocutaneous blisters that initially started in his oral cavity but

rapidly progressed to involve the whole body. Two days prior to the onset of these symptoms, he was started on azithromycin by his primary care doctor for treatment of upper respiratory tract infection. He was allergic to penicillin which caused facial swelling, and he had never been on macrolide antibiotic before. On examination, he was febrile with temperature of 39.5° Celsius, and had sinus tachycardia with heart rate of 110/min. Skin examination revealed multiple, tender vesico-bullous lesions, with surrounding erythema, all over the body including palms and soles. He also had erythema, blistering with sloughing of the oral mucosa and edema with injection of the conjunctiva. The patient was empirically started on acyclovir for disseminated Herpes infection; however it was stopped after all the infectious work up including Herpes, Mycoplasma, and HIV, were negative. Autoimmune work up was also negative. Skin biopsy done on the second day of admission showed interface dermatitis with vacuolar alteration and subepidermal bulla formation with epidermal necrosis, features consistent with Stevens-Johnson syndrome. Immunofluorescence study was negative. Therefore, a diagnosis of azithromycin induced Stevens- Johnson syndrome was made and the patient was transferred to Burn service for extensive care. He improved after supportive treatment with special attention to wound care, ocular care, pain control, fluid and electrolyte balance.

DISCUSSION: Azithromycin, a semisynthetic macrolide, is one of the most commonly prescribed antibiotics in the United States. It is usually well tolerated; however serious side effects like Stevens-Johnson syndrome may rarely occur. There are rare case reports documenting the association of SJS with azithromycin, mostly in children. SJS is a medical emergency which can be fatal if untreated. Early recognition and initiation of supportive therapy is the key to the management of SJS. Physicians should be aware of the unusual association of azithromycin with SJS and thus, limit unnecessary use of this antibiotic.

STONES EVERYWHERE! Sathish kumar Krishnan; Hitu Khaira; Malav P. Parikh. St. Francis Hospital, Evanston, IL. (Tracking ID #1924585)

LEARNING OBJECTIVE 1: – Recognize that pulmonary alveolar microlithiasis (PAM) is a rare parenchymal lung disease often diagnosed incidentally during pulmonary radiography for other reasons.

LEARNING OBJECTIVE 2: – Identify that extra-pulmonary calcifications can be the initial manifestation of PAM.

CASE: A 44 year old gentleman presented for right sided flank pain for 6 days. He denied any constitutional symptoms, nausea, vomiting, diarrhea or dysuria. His past medical history included asthma and infertility. He was on albuterol inhaler as needed. He had 26 pack years of smoking history. His vitals were stable and physical exam was significant for mild tenderness in the right lower quadrant. A CT of the abdomen showed multiple renal stones bilaterally and a 7 mm stone in right ureter just above the ureterovesical junction. He was treated with analgesics and IV fluids. He developed shortness of breath on day 2 of hospitalization. His physical exam revealed diffuse bilateral wheezing and coarse crackles. A chest X-ray revealed bilateral diffuse micro nodular opacities. A CT of the chest showed bilateral diffuse calcified micronodules, interlobular septal thickening, pleural calcification and sub pleural cysts. PFT showed moderate restrictive pattern. He was treated symptomatically with oxygen and bronchodilators, and his shortness of breath improved. Biopsy of the lung showed concentrically arranged laminated calcified bodies and PAS positive psammoma bodies like microliths consistent with PAM. Considering his infertility and the diagnosis of PAM, an ultrasound of the scrotum was done, which revealed decreased left testicular volume and multiple calcified microliths in both the testes and epididymis

DISCUSSION: Pulmonary alveolar microlithiasis is a rare chronic lung disease characterized by deposition of calcium phosphate microliths in the alveoli. The etiology is not clearly evident. It is considered to be due to mutations in the gene encoding a sodium phosphate co-transporter. It is usually diagnosed in the third or fourth decades of life. About one half of the patients exhibit no clinical symptoms and are diagnosed incidentally by pulmonary imaging. Patients who are symptomatic, usually have shortness of breath, non-productive cough and chest pain. Chest X-ray usually demonstrates diffuse bilateral micro-nodular calcifications, predominant in the middle and lower zones. It is described as 'sand storm appearance'. HRCT depicts widespread micro-calcifications and ground glass opacities, which may appear like the 'crazy paving' pattern of alveolar proteinosis. Extra-pulmonary involvement is rare and is characterized by calcifications in various tissues including liver, kidney, pancreas, intestines, testes, ovaries and heart valves. Our patient had nephrolithiasis and calcific depositions in testes and epididymis causing atrophy of the testis and obstructive azoospermia. There is no effective treatment for PAM, with the exception of lung transplantation. The clinical course of the disease is highly variable and the long term survival is unknown. An increased awareness and a better knowledge of the

epidemiological characteristics of the disease could help to diagnose a larger number of cases and to gain insight into its etiology and pathogenesis.

STREPTOCOCCUS AGALACTIAE INFECTIVE ENDOCARDITIS OF A NATIVE MITRAL VALVE Mahmoud Abdelghany; Louis Schenfeld. Conemaugh Memorial Medical Center, Temple University, Johnstown, PA. (*Tracking ID #1923601*)

LEARNING OBJECTIVE 1: Streptococcus agalactiae endocarditis is a virulent invasive infection that can lead to serious complications and death.

LEARNING OBJECTIVE 2: Both medical and surgical treatments are usually necessary for Streptococcus agalactiae endocarditis. Successful medical treatment alone, as in our case, has been reported.

CASE: An 86-year-old female presented complaining of chills, excessive sweating and feeling sick for 2 days. Her past medical history was significant for degenerative mitral valve disease with mitral regurgitation and endometrial cancer for which she had abdominal surgical removal followed by radiation therapy. Postoperative course was complicated with multiple intra-abdominal abscesses, intestinal obstruction and radiation enteritis treated surgically 4 months before that presentation. On admission, her vital signs were stable except for fever with a temperature of 39.1 °C (102.4 °F). Auscultation revealed systolic murmur over the cardiac apex. Two blood cultures were positive for Streptococcus agalactiae (S. agalactiae), also referred as group B streptococcus (GBS). The patient was started on intravenous penicillin G. Transthoracic echocardiography showed mobile vegetation measured 2.15 cm in size, and increased severity of mitral regurgitation compared to an echocardiography done 4 months earlier. CT scan of the head did not show any acute intracranial abnormalities. Combined antibiotic therapy and mitral valve replacement were recommended but the patient refused and requested medical treatment only. She completed four-week course of penicillin uneventfully and without complication. After 9 months, she continued to be asymptomatic with no limitations.

DISCUSSION: S. agalactiae is a rare cause of endocarditis in adults. It is clear that group B streptococcus endocarditis is much more virulent disease than endocarditis due to other streptococci and as virulent as Staphylococcus aureus. Immunocompromised patients are at a higher risk of GBS endocarditis. Transesophageal echocardiography is more sensitive and preferred over the transthoracic echocardiography when transthoracic imaging windows are limited. GBS infective endocarditis may be complicated by major emboli commonly to the brain causing meningitis, brain abscess or encephalopathy. Some genotyping studies had shown that isolates belonging to one particular genotype cluster, sequence type 17 (ST17), are associated with more invasive behavior. Early medical and surgical treatments have been recommended. However, other literatures described cases of GBS endocarditis with favorable outcomes after conservative medical treatment with antibiotics only. Penicillins are the drugs of first choice for the treatment of GBS infections. The benefit of addition of aminoglycosides is still controversial. Although the synergistic effect is confirmed, other literatures could not confirm the superiority of this combination versus penicillin alone. It is clear that GBS endocarditis is a virulent invasive infection. Early antibiotic therapy with or without surgical treatment is crucial to avoid fatal complications.

STROKE AS THE INITIAL MANIFESTATION OF NEPHROTIC SYNDROME Mary Anne S. Chacko; Javad Vaziri; Michael Sheffield. Methodist Dallas Medical Center, Dallas, TX. (*Tracking ID #1936999*)

LEARNING OBJECTIVE 1: Identify presenting symptoms for patients with nephrotic syndrome

CASE: The patient is a 46 year old male with a past medical history significant for hyperlipidemia and hypertension but had no history of renal issues or stroke. He was discovered with left sided weakness and aphasia on the day of admission about 14 h after he was last seen. Home medications included metoprolol and simvastatin. He smoked a pack per day. Family history was significant for hypertension and diabetes. Review of systems was significant for numbness and weakness on his left side. Vital signs on presentation were normal except for BP of 173/84. He could say one or two words. He attended on the right side of his body but neglected his left side. Face was symmetric and without droop. Neck was supple and without bruits. He had no movement in the left upper extremity and decreased movement in the left lower extremity. Toes were upgoing on his left foot. Neurological exam was intact on the right side. Periorbital edema and lower extremity swelling were absent. Significant labs included WBC 17.8, Hemoglobin 15.2, Platelet count 150,000, PT 13, INR 1.0, Creatinine 1.13, Glucose 128, Troponin <0.012, BNP 282 and Albumin 2.4. Lipid panel was abnormal. Urinalysis showed >300 protein and moderate blood, He

excreted 24 g of protein in 24 h. UPEP and SPEP did not show a monoclonal component. Rheumatoid factor was elevated and C3 complement was decreased. CT of the brain indicated an infarct in the right middle cerebral artery distribution with cerebral edema. CT angiogram of head and neck showed occlusion of the M1 segment of the right MCA but no other intracranial stenoses or occlusions. Transesophageal echocardiogram indicated normal left ventricular systolic function and an ejection fraction of 60–65 % with no evidence of thrombus or shunting. Renal ultrasound showed normal arterial and venous blood flow to kidneys and no hydronephrosis. Kidney biopsy showed membranous glomerulonephropathy with secondary focal segmental glomerulosclerosis and mild-moderate arteriosclerosis. The patient did not have significant vascular disease. There was no cardiac evidence of emboli or a shunt. He was anticoagulated with heparin and warfarin and was eventually discharged on aspirin and warfarin with a goal INR of 2.5. He was treated with methylprednisolone and cyclophosphamide for membranous glomerulonephropathy. He was densely hemiplegic at the time of discharge. His neglect had improved, he had better behavior control and was more cognitively aware.

DISCUSSION: Since the first reported association of renal vein thrombosis with nephrotic syndrome in 1837, thrombosis is known to be one of the main complications of nephrotic syndrome. Patients with nephrotic syndrome may have a hypercoagulable state due to several reasons. These include the loss of clotting inhibitors (antithrombin III, Protein C and Protein S) via urinary loss, increased platelet aggregation, decreased fibrinolytic activity, increased concentration of pro-coagulatory factors, hemoconcentration due to hypoalbuminemia and diuretic use and corticosteroid treatment that could increase the concentration of clotting factors and decrease fibrinolytic activity. The hypercoagulability of patients with nephrotic syndrome could be an important trigger for both arterial and venous thromboses. Arterial thromboses are less frequent than venous thromboses and occur most commonly in the femoral arteries. Here we report the case of a patient with ischemic stroke in the distribution of the right middle cerebral artery as the first manifestation of nephrotic syndrome. Thus stroke can be an early manifestation of nephrotic syndrome and should be considered as a possible complication of the syndrome when common causes of ischemic stroke have been excluded. This patient highlights the need for a methodical approach to the patient with a new stroke.

SUBMANDIBULAR MASS WITH GENERALIZED LYMPHADENOPATHY DUE TO IgG4 RELATED DISEASE Sangmee Bae; Soo I. Choi. UCLA, Los Angeles, CA. (*Tracking ID #1933895*)

LEARNING OBJECTIVE 1: Recognize IgG4 Related Disease in a patient with a nonspecific mass or organ enlargement with associated or generalized lymphadenopathy

LEARNING OBJECTIVE 2: Diagnose IgG4 Related disease with characteristic histopathologic findings and IgG4 specific staining

CASE: A 68 year old Korean female with a history of chronic hepatitis B and Hashimoto's thyroiditis presented with bilateral painless firm submandibular masses. She had noticed bilateral neck masses that would alternately appear and resolve over the past few years, and intermittent chills and night sweats without weight loss. CT imaging showed enlarged salivary and lacrimal glands as well as generalized adenopathy of the neck, thorax, abdomen, and pelvis. Further history elucidated mild dry mouth and dry eyes, and exam also demonstrated evidence of lacrimal gland swelling. Laboratory testing was notable for positive ANA at 1:320 titer and elevated ESR at greater than 100 mm/h. Other serologies, including dsDNA, Sm/RNP, SSA/SSB, were negative, and LDH was normal. Fine needle aspiration of the submandibular gland revealed a scant mixed population of lymphoid cells, but was nondiagnostic. Subsequent excisional biopsy demonstrated no malignant cells, but the submandibular gland was marked by dense nodular fibrosis which appeared focally storiform. Further staining showed markedly increased IgG4 positive plasma cells, highly suggestive of IgG4-related sclerosing sialadenitis. Her serum IgG4 levels were also found to be markedly elevated at 1037 mg/dL (normal 8–140 mg/dL) consistent with this diagnosis. She was treated with prednisone leading to prompt resolution of submandibular and lacrimal gland swelling as well as improvement of lymphadenopathy.

DISCUSSION: IgG4 related disease (IgG4 RD) is an increasingly recognized clinical entity, characterized by lymphoplasmacytic infiltrate that stains positively for IgG4-bearing plasma cells in affected organs. Common presentations include a mass or enlargement of the affected organ with associated lymphadenopathy. Historically, it has been described in the head and neck glands (previously called Mikulicz's disease) and pancreas (type 1 autoimmune pancreatitis), but recently clinicians are recognizing that it can involve nearly any organ system, including the orbits, aorta, bile ducts, kidney and lungs. Lymphadenopathy is a common finding in patients, often discovered by generalists who serve as initial providers. Especially when encountered with a tumorous mass or localized swelling in the head and neck, the differential workup should be initiated by the

generalist, and include studies for viral or mycobacterial infection, autoimmune disease such as Sjogren's syndrome, granulomatous disease such as sarcoidosis, and malignancies such as lymphoma or squamous cell carcinoma. IgG4 RD is an important additional differential to consider in these patients which will have significant implications on treatment and prognosis. It is also important to note that greater than 50 % of cases can present with multiple organ involvement and generalized lymphadenopathy. Diagnosis of IgG4 RD requires immunohistochemical staining specific for IgG4, which is typically not routinely performed. Distinctive histopathological patterns include prominent infiltration of lymphocytes and plasma cells with storiform or swirling fibrosis as well as obliterative phlebitis. Mild peripheral eosinophilia and elevated serum IgG4 levels may also provide additional evidence to support the diagnosis of IgG4 RD. While lymphoproliferative malignancies are treated with systemic chemotherapy, IgG4 RD is treated with systemic glucocorticoids as a first line agent, and additional immunosuppressive therapy such as azathioprine, mycophenoate mofetil, and rituximab may be used in recurrent or refractory cases. Distinctive histopathological patterns include prominent infiltration of lymphocytes and plasma cells with storiform or swirling fibrosis as well as obliterative phlebitis. Mild peripheral eosinophilia and elevated serum IgG4 levels may also provide additional evidence to support the diagnosis of IgG4 RD.

SURVIVING PAINLESS JAUNDICE-A TEST FOR PATIENT AND PHYSICIAN Abdul Haseeb; Jeannine Engel. University of Utah School of Medicine, Salt Lake City, UT. (*Tracking ID #1939659*)

LEARNING OBJECTIVE 1: Diagnose drug induced liver injury.

LEARNING OBJECTIVE 2: Recognize when to manage markedly elevated bilirubin levels with watchful waiting and no invasive testing.

CASE: A 92-year-old male with a history of ischemic cardiomyopathy and atrial fibrillation on chronic Coumadin therapy, presented to the acute-care-clinic with complaints of painless jaundice, pruritus, dark urine, and decreased appetite. The patient denied any history of hepatitis or alcohol use. Laboratory findings were significant for elevated total bilirubin 17.5 mg/dl, direct bilirubin 10.8 mg/dl, INR 4.8, alkaline phosphatase 1023 U/L, AST 230 U/L, and ALT 227 U/L. CT scan of the abdomen showed no abnormalities of the liver, pancreas or biliary tree. Initial assessment included a full review of his medication history. Two weeks prior to his current presentation, he later recalled completing a seven-day course of amoxicillin/clavulanate for a diagnosis of acute sinusitis. This was thought to be the culprit for his drug induced liver injury. Given the elevated INR, the patient's Coumadin was stopped and his INR returned to therapeutic range within 4 days. The patient was treated symptomatically for his pruritus and started on Ursodiol when his bilirubin level surpassed 30 mg/dL. The patient's liver enzymes and total bilirubin peaked 1 week after the initial presentation and then started to gradually downtrend. Although he felt better within 4 weeks, it took nearly 4 months for his laboratory values to normalize. No invasive procedures or additional imaging were performed, and no specialty consultations (save a phone call) were obtained.

DISCUSSION: The differential diagnosis of jaundice is large. To narrow the list, the pattern of hepatocellular, cholestatic, or isolated hyperbilirubinemia can be discerned from the liver function test (LFT) pattern. Once neoplasms and dilated bile ducts have been excluded with imaging, and the usual infectious and toxic exposures and alcohol disqualified by history, and inherited disorder made unlikely by the patient's age, suddenly the possible diagnoses are fairly small. What seemed to be a death sentence on presentation for our patient, was rapidly becoming good news. Drug induced liver injury (DILI) has an incidence of 13.9+2.4 cases/100,000 and is estimated to affect 44,000 individuals annually in the United States. Despite the low incidence, 10 % of the patients with drug-induced jaundice will die. Most cases of DILI are due to either a dose dependent acetaminophen-type reaction or an idiosyncratic reaction. The data from prospective registries, such as the Drug Induced Liver Injury Network, indicates amoxicillin/clavulanate as a major culprit of idiosyncratic reactions. DILI can be classified based on the pattern of the liver injury: hepatocellular, cholestatic, or mixed. DILI remains a diagnostic challenge. Diagnosis of DILI is usually made through the process of causality assessment, which interestingly is similar to any criminal investigation. A few steps include: "Was the drug in the right place at the right time?", "Does this drug have a prior record?", "Are the characteristics of liver injury consistent with the implicated drug?", "Are there other more reasonable explanations for the liver injury?". Depending on the case scenario and the comorbidities, testing for Hepatitis A, B, C and sometimes E, iron/copper overload, alpha-1-antitrypsin deficiency, Celiac disease, alcohol abuse, and ultrasound of the liver are to be undertaken before diagnosing DILI. Amoxicillin/clavulanate is known to cause cholestatic or mixed liver injury with jaundice approximately 2 to 3 weeks after the medication has been stopped, as seen in our case described above. Hence, prior medication history is key in making the diagnosis. Improvement of the liver function tests is slower with drugs that induce a cholestatic injury compared to hepatocellular

injury. Hepatic necrosis is uncommon in cholestatic injury, thereby having a lower mortality when compared to the other patterns. The rates of hepatic necrosis are 3 % in amoxicillin/clavulanate, compared to 65 % with isoniazid related hepatocellular injury. Elderly patients, like in our case, are prone to cholestatic/mixed pictures of DILI. Several strategies can be used to prevent DILI, which include patient/physician education, liver function test screening, and active legislation to restrict the potentially toxic drugs. Clinicians can utilize the National Library of Medicine "LiverTox" database, which uses prospective registries as an excellent point of care resource to identify potential drug culprits. When presented with patients such as our elderly gentleman, with impressively high lab values which continue to increase, the fallback is often to consult or proceed with invasive testing. Sometimes the best medicine is to do nothing.

SWEET PEE: AN UNCOMMON CAUSE OF GLYCOSURIA James M. Kuo^{1,2}; Carmen M. Ramis¹; ¹Weill Cornell Medical College, New York, NY; ²New York Presbyterian Hospital, New York, NY. (*Tracking ID #1933883*)

LEARNING OBJECTIVE 1: Distinguish between the different causes of glycosuria
LEARNING OBJECTIVE 2: Treat diabetes using medications that work via glycosuria

CASE: 28 yo male presented for an initial visit for STI screening and right sided back pain worse with movement. No hematuria, dysuria, or foamy urine. Past medical history remarkable for right sided nephrolithiasis 1 year ago. No medications or allergies. Family history notable for type 2 diabetes in aunt and grandmother and hypertension in mother and aunt. Social history of binge drinking on weekends, smoking 2–3 cigarettes/day, and describes himself as Hispanic. On exam, T 37C, HR 80, BP 120/80, RR 16, BMI 33.3. HEENT: NC/AT, PERRL, EOMI; Neck: no acanthosis; CV - rrr, no m/r/g; Lungs - ctab; Abd - obese, +bs, soft, nt/nd; MSK - no deformity, pain reproducible with movement, no flank tenderness. Labwork notable for dipstick UA - >2000 glucose, pH 5.0, no blood or protein. Formal UA confirmed >1000 glucose, pH 6.0, and no blood or protein. Pt had non fasting labs of Na 138 K 3.8 Cl 100 HCO₃ 24 BUN 17 Cr 0.77 Gluc 140 Ca 9.2. His A1c was 5.7 %. Repeat UA demonstrated >250 glucose, pH 6.0. STI screening was negative. The patient's back pain improved with acetaminophen.

DISCUSSION: The most common cause of glycosuria is diabetes mellitus where sodium-glucose co-transporters (SGLT2) in the proximal convoluted tubule, which reabsorb 90 % of filtered glucose, become saturated and glycosuria usually commences once blood glucose levels are >185 mg/dl. It is unlikely in this patient given his A1c of 5.7 %. Fanconi syndrome causes global proximal convoluted tubule dysfunction and can also lead to glycosuria. Causes include genetic abnormalities, heavy metal poisoning, medications, and amyloid. Patients typically have bicarbonate wasting, urine pH<7.5, and electrolyte abnormalities, none of which were present in this patient. Patients with nephrotic syndrome may have glycosuria but this patient did not have protein in his urine and lacked symptoms. Finally, familial renal glycosuria causes glycosuria via a defect in the SGLT2 transporter. It is very rare with a prevalence estimated to be 0.29 %. It is the most likely diagnosis in this patient as he repeatedly has large glycosuria in the absence of hyperglycemia or other renal dysfunction. The diagnosis can be confirmed via genetic testing, but it has a benign outlook so further testing is generally not indicated. Case reports indicate that some patients may have an increased risk of UTIs but otherwise no long term adverse effects. Further outcomes can be extrapolated from SGLT2 inhibitor drugs, such as canagliflozin, which are now being used to treat diabetes. Benefits include an A1c reduction ~0.5–0.7 %, weight loss via glycosuria ~1.8 kg, modest blood pressure reduction ~4.5 mmHg, and rare hypoglycemia. However, patients have an increased risk of genitourinary infections and the long-term cardiovascular and renal safety profiles are still unknown. This patient's glycosuria likely protected him from becoming diabetic despite multiple risk factors, including obesity, Hispanic ethnicity, and family history.

SWOLLEN FEET AND PALPITATIONS AFTER DRAINING A PNEUMOCOCCAL EMPYEMA Ankita Tandon; Cynthia H. Chuang; Jed Gonzalo; Eileen Henrikus. Penn State University Hershey Medical Center, Hershey, PA. (*Tracking ID #1934365*)

LEARNING OBJECTIVE 1: Recognize that large volume thoracentesis can result in systemic effects of hypoproteinemia.

CASE: Empyema is a life threatening complication of pneumococcal pneumonia requiring tube thoracostomy to drain the exudate. Common complications of chest tube placement include pneumothorax, tension pneumothorax, infection and organ perforation. The lesser recognized complication of systemic hypoproteinemia with resulting fluid shifts can result in significant complications. Fifty-three-year-old woman with no medical

history presented with fatigue, low-grade fevers, dyspnea and left-sided pleuritic chest pain. Physical exam revealed no breath sounds in the left lung, labs were significant for leukocytosis, hyponatremia, and a slightly low albumin level at 3.2 g/dL. Chest CT showed numerous large loculated left-sided fluid collections. Three simultaneous chest tubes were placed and streptokinase was administered, resulting in the drainage of 3 L of purulent fluid over the next 3 days. By day four, her leukocytosis, fever, dyspnea and chest pain had improved, but she developed new 2+ lower extremity edema and palpitations. Physical exam revealed a pericardial rub. Subsequent work-up revealed a markedly low pre-albumin level (10 mg/dL), an electrocardiogram showed atrial flutter with rate of 170 beats per minute, and echocardiogram revealed a moderate pericardial effusion without tamponade physiology. Presumed diagnosis was pericardial effusion and peripheral edema as a complication of protein loss associated with large volume thoracentesis. With protein supplements and diuretics, the effusion and lower extremity edema improved. After a week, the chest tubes were removed. She was discharged on anticoagulation and a beta-blocker for heart rate control. She was cardioverted a month later. At subsequent follow-up appointments, she has clinically improved and repeat chest x-rays are clear.

DISCUSSION: We report a case of lower extremity edema and pericardial effusion resulting from protein loss and decreased oncotic pressure upon removal of 3 L of purulent fluid from the pleural space. Although, she was also hypoalbuminemic to begin with, so a part of these fluid shifts was from the disease process itself. While total protein loss is known to occur after tube thoracostomy, systemic manifestations resulting from decreased oncotic pressure is a less reported complication. Therefore, it is unclear if there are patients at particularly high risk who may benefit from a high protein diet prior to large volume empyema-related thoracostomy. It is also unclear whether such patients need to be preemptively placed on cardiac monitors despite no cardiac history due to risk of developing arrhythmias with pericardial effusions. Either way, one must be vigilant of subsequent systemic side effects of a seemingly localized pulmonary process that was treated and improving.

SYMPTOMATIC HYPOCALCEMIA, VITAMIN D DEFICIENCY AND ANEMIA Eunice Chuang. Mount Auburn Hospital, Cambridge, MA. (*Tracking ID #1940011*)

LEARNING OBJECTIVE 1: To recognize that hypocalcemia, vitamin d deficiency and anemia are presenting symptoms of celiac disease.

CASE: A 22-year-old female without past medical history presented with numbness and tingling in the extremities as well as cramps in her hands and calves for the past few weeks. She also noted that she has a history of fatigue for many years. Denies weight loss. Has had intermittent nonbloody diarrhea for many months. Physical exam showed stable vitals and remarkable for palor. Lab showed hemoglobin of 5.8 g/dL, MCV of 61.7, MCH 16.2 and calcium of 5.8 mg/dL, albumin of 3.2 mg/dL, PTH was elevated at 296 and vitamin D was low at 5 ng/ml. Iron studies showed undetectable iron and ferritin of 4. She was started on IV calcium supplementation with good response. Endocrinology and GI were consulted. Celiac studies were sent with positive endomysial antibody and gliadin IGA. Patient was discharged with instructions of gluten free diet and on calcium and calcitriol supplementation and close follow up with primary care physician.

DISCUSSION: Celiac disease is an immune-mediated inflammatory disorder of the small intestines induced by the prolamins of certain cereals causing loss of villous height, crypt hyper trophy leading to malabsorption. It is one of the most common lifelong disorders in Europe and the USA. In adults, presentation of celiac disease varies from asymptomatic to severely symptomatic, depending on the severity and the extent of mucosal involvement. Gastrointestinal symptoms are more common and include other conditions such as diarrhoea, weight loss, malaise, lethargy and abdominal pain. It is important to recognize vitamin D deficiency and hypocalcemia as presenting symptom of celiac disease. Hypocalcaemia is thought to occur due to the negative calcium balance, due to loss of villous surface area, with unabsorbed calcium binding to excess fatty acids in the intestinal lumen as a result of fat malabsorption. There is impairment of active intestinal calcium transport mechanisms because of depletion of calbindin from enterocytes. Decreased vitamin D also contributes to decreased calcium absorption. Hypocalcaemia stimulates PTH to correct for low calcium level. Secondary hyperparathyroidism occurs due to vitamin D and calcium malabsorption. It is important to recognize that hypocalcemia, vitamin D deficiency, elevated PTH in a patient with anemia can be signs of malabsorption, which can lead to diagnosis of celiac disease.

SYNCOPE DUE TO COLD WEATHER Sparsha Kukunoor; Poojita Shivamurthy. University of Connecticut, Hartford, CT. (*Tracking ID #1939777*)

LEARNING OBJECTIVE 1: Identify the association between acute hemolytic anemia and syncope.

LEARNING OBJECTIVE 2: Recognize the importance of finding cold agglutinins on peripheral smear.

CASE: 81 year old female presented to the emergency room after witnessed syncope while working outside in the cold doing volunteer work for her church. Her syncopal event was not preceded by aura, fatigue and lasted a few seconds. On coming to the emergency room she was short of breath and fatigued. Further questioning revealed a similar episode 2 years ago, during which time she was diagnosed with cold agglutinin disease with titers of 1: 512. Laboratory investigations revealed hemoglobin of 6.9 g/dL from a baseline of 10.0 g/dL. Peripheral smear was found to have cold agglutinins. This was confirmed with direct anti-globulin test which showed positive poly-specific test and mono-specific test positive for complement protein C3d/C3b and negative for IgG. She was admitted and was given warmed packed red blood cells. Other laboratory data revealed monoclonal gammopathy, IgM kappa type with M component of 0.67. Bone marrow biopsy and CT of abdomen and pelvis showed no evidence of lymphoproliferative disease. She dramatically improved the next day and did not require any further transfusions.

DISCUSSION: Cold agglutinins (CA) are antibodies that agglutinate erythrocytes at an optimum temperature of 0-4°C. CA may be found in the serum of normal individual in the polyclonal form however in Cold Agglutinin Disease (CAD) they are monoclonal and in high titers (1). Usually effects female population in the 7th decade. CAD has an incidence of one in one million per year. A single institutional experience showed that in patients with 43,000 patients having a monoclonal gammopathy, less than 1 % had cold-reactive autoantibodies (2). The autoantibodies can be primary as in our case or secondary due to autoimmune disease, malignancy or infections. Clinical features include anemia, cold induced symptoms like acrocytosis, Raynaud disease, livedo reticularis and sometimes cutaneous necrosis. Diagnosis is made by positive Coombs test to anti - C3, CA titers and thermal activity. Work up including a bone marrow aspiration should be done for secondary causes. Non-pharmacological management like avoidance of cold is the cornerstone of therapy. Studies as lacking and thermal amplitude of the CA antibody in many patients is such that physiologic peripheral cooling results in antibody binding sufficient to cause anemia. Pharmacological therapy has been unsuccessful until recently. Half of the patients respond to rituximab monotherapy. Fludarabine-rituximab combination therapy is very effective, resulting in 75 % response rate, Complete remissions in about 20 %. Toxicity is a concern, and benefits should be carefully weighed against risks (1).

SYSTEMIC LUPUS ERYTHEMATOSUS MIMICKING SEPSIS Ming Zhao¹; Charu Ramchandani¹; Peter M. Deane²; Carlos D. Palacio¹. ¹Unity Health System, Rochester, NY; ²Allergy-Asthma-Immunology of Rochester, PC, Rochester, NY. (*Tracking ID #1939134*)

LEARNING OBJECTIVE 1: Recognize neuropsychiatric symptoms in systemic lupus erythematosus (SLE).

LEARNING OBJECTIVE 2: Distinguishing SLE flare from sepsis.

CASE: Patient is a 38 year old female who was admitted to hospital due to worsening weakness, fatigue, shortness of breath and constant headache. Her past medical history was significant for systemic lupus erythematosus (SLE) diagnosed 20 years ago. Patient stopped treatment for SLE 3 years ago. At the time of her admission, she was found to have systemic inflammatory response syndrome (SIRS), with WBC 14500, respiratory rate 36/min and heart rate 120/min. On examination patient was somnolent, breath sounds were decreased at the left lung base with scattered rhonchi and fine rales. Her labs were remarkable for white blood cell count (WBC) 14500, Hemoglobin 10 g/dL and serum creatinine 1.52 mg/dL. Shortly after admission, patient spiked high fever of 40° celsius along with worsening severe headache, increased confusion, irritability, memory impairment and lethargy. Given her severe headache, fever and SIRS, there was concern for sepsis secondary to meningitis/encephalitis. CT head and MRI/MRV did not show any abnormality. Cerebrospinal fluid (CSF) showed normal WBC, glucose and protein level with gram stain negative for organisms. She was empirically treated with Vancomycin, Ceftriaxone, Ampicillin and Acyclovir. However, given her history of SLE, there was also concern for SLE flare which could have led to her symptoms. Urine analysis was remarkable for 3+ proteinuria and numerous red cells. Chest x-ray showed cardiomegaly and small bilateral pleural effusions. Echocardiogram showed batrial enlargement, right ventricular dilatation, severe tricuspid regurgitation, moderate mitral regurgitation, and 55 % left ventricular ejection fraction. We checked her serum C3 and C4 complement level, which were very low. We also checked her serum C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and ds-DNA, which all came back highly elevated. Rheumatology was consulted, following which she was started

on intravenous cyclophosphamide and methylprednisone. Antibiotics were stopped. Eventually her fever and headache resolved and her mental status improved markedly. Over the course of her stay her ESR came back to normal and CRP improved. Her renal biopsy showed stage 4 lupus nephritis.

DISCUSSION: Neurologic and psychiatric symptoms are commonly seen in patients with SLE, either prior to the diagnosis or during the course of their illness. Neuropsychiatric systemic lupus erythematosus (NPSLE) is associated with a worse prognosis and more cumulative damage and represent an important cause of morbidity and mortality in SLE. Unfortunately, there are no diagnostic tests that can establish a specific diagnosis of NPSLE, and thus, the approach to patients with neuropsychiatric symptoms require establishment of the diagnosis of SLE and distinguish from other causes of nervous system abnormalities, such as medication effects, metabolic abnormalities and infection. It is always important to suspect infection in patients with SLE and central nervous system manifestations. Immune response in SLE is impaired due to defect in different components of humoral and cell mediated immune process, making patients prone to infection. Immunosuppressive action of the standard therapeutic regimen also increases the susceptibility to infection. However, sometimes, clinical manifestations of SLE can be indistinguishable from infection. Patients with highly active SLE may present with a picture mimicking infection or even sepsis. With severe inflammation and disease activity, such patient may present with high fever, tachycardia, hypercapnea and high WBC, just like our patient. In such circumstance, patients may benefit from immunosuppressive treatment such as corticosteroids, rather than antibiotics. Certain medications, such as Acyclovir, may even give patient a higher risk of worsening renal function and should be avoided as possible as we can. A typical workup for such circumstance may include a detailed history and physical exam to look for any clues of infection, serologic and imaging studies to look for the severity and activity of the disease as well as the possibility of underlying infection. A high ds-DNA titer may indicate highly active SLE rather than infection. Also complement levels are low in SLE flare versus high in infection. Other biological markers reported in several studies to identify infection in SLE patients are CRP, sedimentation rate, ferritin, procalcitonin, and delta neutrophil index. In conclusion, neuropsychiatric symptoms are commonly seen in patients with active SLE and should be distinguished from infection such as meningitis/encephalitis. Highly active SLE may also present with a picture mimicking infection or even sepsis. The diagnoses and treatment should always be based on a comprehensive evaluation.

TAKOTSUBO CARDIOMYOPATHY WITHOUT AN ACUTE STRESS TRIGGER

Ranjan Pathak; Paras Karmacharya; Leena Jalota; Benjamin Lloyd. Reading Health System, West Reading, PA. (*Tracking ID #1938289*)

LEARNING OBJECTIVE 1: Clinicians should consider Takotsubo cardiomyopathy in the differential diagnosis of patients presenting with chest pain, even without a history of recent stress.

CASE: A 92 year old female with no significant cardiac history presented to the emergency room complaining of non-radiating pressure-like chest discomfort of 2 h, dyspnea, nausea and vomiting. She denied any history of recent stress. Her Serial EKGs revealed dynamic changes with inferior, anterolateral ischemic changes with ST elevation and T inversion. A diagnosis of inferior wall STEMI and acute congestive heart failure was made. Given her age, a decision was made to manage her conservatively. However, she continued to have chest discomfort with rising Troponin (peak 14.09), CK-MB levels and was ultimately taken for cardiac catheterization on the third day. Coronary angiography showed non-obstructive coronary artery disease. Left ventriculography revealed hyperdynamic basal segment with a normal apex. The mid segment was severely hypokinetic to akinetic consistent with atypical TC. She was medically managed with aspirin, statin, beta blocker, and ACEI with significant improvement in symptoms.

DISCUSSION: Takotsubo cardiomyopathy (TC) is an acute segmental myocardial dysfunction of the left ventricle without significant lesion of the coronary artery. It presents with chest pain, electrocardiographic changes and elevated troponins frequently masquerading as acute coronary syndrome. Of the four variants, the most common type consists of apical ballooning and with hyperkinetic or normal basal region. TC is usually associated with acute or chronic emotional or physical stress. While the role of chronic stress in TC is unknown, stress as trigger may be absent in 15 % of cases. The mid ventricular variant is seen in about 17 % of the cases. The absence of the common apical left ventricular abnormality and lack of preceding stressor makes our case atypical. Clinicians should be aware of this unique syndrome, its variants and consider this in the differential diagnosis of patients presenting with chest pain, especially in post-menopausal women even without a history of recent stress.

TB OR NOT TB: TUBERCULOUS ENTERITIS PRESENTING AS APPENDICITIS

Jaimin Amin; Arthur Jeng; Stanley K. Dea. Olive View-UCLA Medical Center, Sylmar, CA. (*Tracking ID #1939731*)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of tuberculous enteritis and discuss the appropriate diagnostic and therapeutic management

LEARNING OBJECTIVE 2: Differentiate between M. tuberculosis and M. bovis

CASE: A 56 year-old Mexican man presented with 2 days of severe abdominal pain accompanied by fevers, weight loss, and non-bilious emesis. On examination, he was febrile and tachycardic with rebound tenderness of the epigastrium and perumbilical abdomen. Laboratory studies were significant for WBC 7.1 with 80 % neutrophil predominance, hemoglobin 8.4 with MCV 79, BUN 31 and Cr 1.1 and isolated alkaline phosphatemia 303. An abdominal CT scan demonstrated two large complicated cystic lesions with lymphadenopathy. The first lesion measured 5×5 cm and was located in the right lower quadrant adjacent to the third portion of the duodenum with a dilated appendix concerning for perforated appendicitis. The second lesion measured 3×3 cm and was found within the body of the pancreas suggestive of pancreatic malignancy. Surgery was consulted for exploration and appendectomy but deferred. Endoscopic guided biopsy of the pancreatic cyst was unremarkable. CT guided drainage of the right abdominal cyst revealed acid-fast bacilli, which grew M. tuberculosis complex, identified as M. bovis. Initiation of rifampin, isoniazid, and ethambutol resulted in resolution of symptoms and normalization of imaging.

DISCUSSION: This case emphasizes a lesser common clinical presentation of tuberculosis, that involving the GI tract. Although the initial evaluation was suggestive of appendicitis and/or pancreatic malignancy, further evaluation by CT guided drainage led to the demonstration of acid fast bacilli and the diagnosis of tuberculous enteritis from M. bovis. M. tuberculosis and M. bovis are related to the extent that it is not possible to distinguish these two mycobacteria by genetic amplification means (eg. PCR). However, they are distinguishable by biochemical means. They can both tuberculosis in humans, although their epidemiological reservoirs are different. M bovis is known to cause tuberculosis in cattle and may have evolved into M. tuberculosis. However, humans can be infected with this zoonotic pathogen by consuming unpasteurized dairy products from afflicted cattle. Because of the oral route of entry, M. bovis most commonly presents within the GI tract. Due to their ability to survive in mononuclear leukocytes and the density of lymphoid tissue within Peyer's patches. M. bovis enteritis frequently mimics appendicitis or colon cancer, which are commonly the initial diagnoses. Suspicion for M. bovis, rather than M. tuberculosis, should arise when the isolate is resistant to pyrazinamide (PZA), given its universal genotypic resistance to this anti-mycobacterial drug. Treatment involves 6–9 months of standard anti-tuberculous medication, with the exception of PZA.

TENSION PNEUMOTHORAX IN OUT-PATIENT CLINIC

Manisha Bhide. University of Colorado Denver, Aurora, CO. (*Tracking ID #1923481*)

LEARNING OBJECTIVE 1: To recognize that certain causes of dyspnea need urgent triage. Relatively stable outward appearance may be deceptive in cases of chest pressure and dyspnea

CASE: 39 year old male teacher, nonsmoker came to out-patient medical clinic with 7 days of worsening dyspnea, moderately severe chest pressure, dry cough and pleuritic chest pain. Past medical history was significant for hypertension, seasonal allergies and mild intermittent asthma. Family history was noncontributory. Exam revealed afebrile patient with heart rate of 96/min, BP 130/86 and respiratory rate of 18/min with increased work of breathing. Breath sounds were decreased on Rt side. Rt sided hyper resonance was present on percussion. EKG showed normal sinus rhythm with Rt axis deviation. Chest X-ray showed large right tension pneumothorax. Urgent Chest tube with water seal device and suction placement was done. Pneumothorax resolved over 4 days. CT Chest did not show any blebs or lung abnormality.

DISCUSSION: Differential diagnosis of dyspnea and pleuritic pain in a young male includes pulmonary embolism, pleurisy, autoimmune diseases and pericarditis. Chest pain with dyspnea and respiratory abnormalities should stimulate us to put pulmonary pathology higher on the list of differential diagnosis. Hyper resonance on percussion can indicate COPD, but in a young male, nonsmoker it could be due to pneumothorax. Presence of air in the pleural space, with no obvious underlying lung pathology or HIV or trauma, is termed as spontaneous pneumothorax. The incidence ranges from 7.4 to 18/100,000 per year among men. The incidence is lower in women at 1.2/100,000. Smoking, connective tissue disease and family history are thought to increase the risk by sub-pleural bullae formation and degradation of elastic tissue. The American College of Chest Physicians has established guidelines for management of spontaneous pneumothorax. For large pneumothorax, hospitalization and placement

of chest tube with water seal device, with or without suction is recommended. Procedures to prevent recurrence, like pleurodesis are usually reserved only for second occurrence or for professionals like pilots and divers. Routine Chest CT is not recommended to find cause for first time pneumothorax, but CT may be done for management of secondary or complex pneumothorax. Shift of mediastinum along with unstable vitals like tachycardia, hypotension are indicative of tension pneumothorax. This case is important to remember because outwardly stable patients can conceal a tension pneumothorax which can lead to compression of the mediastinum and can have rapid clinical deterioration and death if unrecognized.

TERTIARY LGV DIAGNOSIS AFTER FISTULOTOMY: UNDER-SCREENED, UNDER-DIAGNOSED, AND UNDER-TREATED Robert Spencer; David M. Levine; Richard E. Greene; Andrew A. Chang. New York University Medical Center, New York, NY. (*Tracking ID #1939016*)

LEARNING OBJECTIVE 1: Formulate a differential diagnosis for rectal pain in MSM

LEARNING OBJECTIVE 2: Recognize and diagnose lymphogranuloma venereum
CASE: A 27 year-old gay man presented to the ED with 2 weeks of much-worsened 7/10 rectal pain with bloody purulent discharge, fevers, chills, tenesmus, and a week of a rapidly enlarging tender L-sided inguinal mass. Five years prior to presentation he was the victim of a sexual assault involving forced receptive rectal penetration by the assailant's penis and a sharp object causing a rectal abscess requiring incision and drainage (I&D) and infection with HIV. Until last year, he noted only mild rectal tenderness without drainage. At that time (CD4 800 [40 %], VL <20, on ART × 4 months), he noted progressive pain with purulent discharge from the previous incision site, prompting a second I&D that failed to entirely heal despite various PO antibiotic regimens over months. On exam, a 1 cm-long 9-o'clock perianal skin break without tenderness, fluctuance, or erythema, and a tender 5×2 cm mobile L-inguinal mass were noted. Blood work and urinalysis were within normal limits including urine cultures, urine gonococcal/chlamydial NAAT, blood cultures, RPR, and quantiferon gold. A CT scan demonstrated rectal wall thickening with surrounding infiltrative change and left inguinal lymphadenopathy without abscess. We clinically diagnosed lymphogranuloma venereum (LGV) and initiated treatment with doxycycline. Endoscopic ultrasound and fistulogram revealed an anal fistula, which was excised. Subsequent novel PCR analysis of the formalin-fixed paraffin embedded fistula specimen confirmed Chlamydia trachomatis serovar L2, while the NAAT rectal swab also confirmed Chlamydia. The patient's inguinal lymphadenopathy and rectal pain subsided entirely following a 21-day course of doxycycline.

DISCUSSION: Taking an in depth history and formulating a broad differential for rectal pain in MSM are essential. We considered the differential for proctitis: infectious (C. trachomatis, N. gonorrhoeae, HSV, syphilis, intramuscular abscess, LGV), anatomic (trauma, hemorrhoids, cryptitis, anal fissure, rectocele), ischemic, malignant, and proctalgia fugax. We also considered the causes of inguinal adenopathy: chancroid, herpes, syphilis, LGV, lymphoma, tuberculosis, abscess, and bubonic plague. LGV was rarely reported in industrialized countries prior to 2003, when the first of many reports circulated in what has now been termed a "silent endemic disease" of MSM. LGV is a sexually transmitted infection caused by serovars L1-L3 of C. trachomatis, due to their tropism for lymphatic tissue. Risk factors include co-infection with HIV and/or hepatitis C, along with high-risk sexual behavior. Primary LGV presents with a frequently unnoticed painless genital papule or mucosal inflammation at the site of inoculation that may ulcerate and heal spontaneously. Secondary LGV presents 2 to 6 weeks later with involvement of lymph nodes that drain the area of the primary lesion. This may go unnoticed when primary infection occurs in the rectum, as the deep iliac nodes are often less symptomatic. Tertiary LGV involves chronic granulomatous change and lymphatic obstruction leading to fistula and stricture formation. In the US, LGV largely remains a clinical diagnosis, as no commercial PCR assays are available for serovars L1-L3. This often leads to delayed diagnosis and treatment, as in the case of our patient. Providers must be aware of LGV's resurgence and consider rectal screening in MSM.

THE ANTIBIOTIC THAT CAUSED THE ITCH: INTRACTABLE PRURITIS AND JAUNDICE AFTER TREATMENT FOR SINUSITIS Jack Badawy; Ashley Garcia-Everett; Kanapa Kornsawad. University of Texas Health Science Center, San Antonio, TX. (*Tracking ID #1938988*)

LEARNING OBJECTIVE 1: Recognize medication adverse reaction as an important cause of liver failure

LEARNING OBJECTIVE 2: Emphasize a thorough history as a key diagnostic tool in medicine

CASE: A 71-year-old man with no significant past medical history presented with 1 week of intractable pruritus, jaundice, and anorexia. He initially noticed darkening of his urine which progressed to painless jaundice over the next few days. He denied a history of alcohol use. Home medications included aspirin, fish oil and a multivitamin. He had recently completed a 3 week course of amoxicillin-clavulanate for chronic sinusitis. He had no familial history of liver disease. On physical examination he was afebrile, jaundiced with scleral icterus, had multiple excoriations to his limbs and no hepatosplenomegaly. Initial laboratory results demonstrated aspartate and alanine aminotransferases of 171/380 IU/L, alkaline phosphatase of 260 IU/L, T.bilirubin of 5.2 mg/dL and INR of 1.3. Serological evaluation for viral hepatitis and autoimmune hepatitis were negative. A liver ultrasound was normal. He had a normal MRCP and eventually an EUS and ERCP with sphincterotomy and stent placement. Bile duct biopsy and brushing were normal. Liver biopsy showed extensive intrahepatic cholestasis with bile plugs suggestive of large bile duct obstruction which in the given clinical setting were consistent with drug toxicity related to amoxicillin-clavulanate therapy. His pruritis was refractory to multiple therapies including ursodeoxycolic acid, cholestyramine, rifampin and prednisone. His hyperbilirubinemia (peak total bilirubin of 20 mg/dL), coagulopathy and transaminitis began to improve with supportive measures prior to discharge.

DISCUSSION: Idiosyncratic drug induced liver injury is responsible for 11.1 % of all cases of acute liver failure, with antimicrobials being the most common causative group. Of antimicrobials, amoxicillin-clavulanate has the highest incidence of drug-induced hepatotoxicity accounting for 13–23 % of cases. Males are most commonly affected with a mean age of 60; longer duration of treatment (>2 weeks) is also associated with higher risk. Hepatotoxicity is clearly linked to the clavulanic acid moiety, with a 5- to 9-fold increase for the combination versus amoxicillin alone, giving an estimated incidence rate of 9.91 cases of jaundice per 100,000 prescriptions of amoxicillin-clavulanate. The cause is often elusive because the symptoms typically arise after completion of the antibiotic regimen (average delay of 17 days) and therefore a thorough inquiry into drug history is key. Treatment includes withdrawal of the offending agent and symptom management with ursodeoxycolic acid (which may improve the cholestasis) and cholestyramine. Despite this some patients may progress to fulminant hepatic failure resulting in transplantation or death. Amoxicillin-clavulanate is one of the most widely prescribed antibiotics worldwide. Reports of adverse reaction with cholestasis, abnormal liver function test were less than 1 %, however, while rare, the morbidity and mortality associated with drug induced hepatotoxicity is significant. This case emphasizes the importance of the judicious use of antibiotics.

THE CASE OF MS. A. EARLY SUPPORT FOR A GRASS-ROOTS, TEAM-BASED APPROACH TO AMBULATORY CARE IN A RESIDENT CLINIC Nora Segar; Manik Chhabra; Janet J. Ho; Megan S. Lemay; Faye Farber; Sarita Soares; Julie R. Rosenbaum; Stephen Holt; Tracy Rabin. Yale University, New Haven, CT. (*Tracking ID #1939139*)

LEARNING OBJECTIVE 1: Identify the challenges of caring for complex patients in a traditional model of ambulatory resident education.

LEARNING OBJECTIVE 2: Describe the implementation and potential benefits of a resident-organized, team-based outpatient care model.

CASE: Ms. A is a 52-year-old, unemployed, high-school-educated, Puerto Rican mother of three, and the primary care giver for her grandson and frequently hospitalized mother. She has uncontrolled diabetes with average hemoglobin A1C of 11, hyperlipidemia, asthma, tobacco dependence, hidradenitis suppurativa with recurrent groin abscesses, uncontrolled depression with history of a prior suicide attempt, and chronic pain secondary to spinal stenosis and adhesive capsulitis, managed with opioids. Of note, she has previously violated the clinic's controlled substance agreement by taking non-prescribed opiates for worsening pain. Lead author NS has followed Ms. A at our resident continuity clinic since starting training 2 ½ years ago. During this time she has seen Ms. A 20 times and spoken with her over the phone on a weekly basis. In our established care model, NS cares for her with the support of a faculty preceptor. When NS is unavailable, other residents not familiar with Ms. A provide interim care. Our clinic does not currently employ social work staff, full-time mid-level providers, or a dedicated behavioral health team integral to the successful multidisciplinary care of patients like Ms. A. These resource limitations, in combination with complex resident schedules that often prioritize inpatient rotations, result in a fragmented clinical experience. For example, in addition to three hospitalizations and six emergency department visits, Ms. A has been seen 15 times by 11 distinct clinic providers other than NS in the past 2 ½ years. One model for effective outpatient care and improved training environment is the Patient Centered Medical Home (PCMH), a team-based, multidisciplinary approach to primary care for complex patients. At our clinic, a core group of interested

residents have organized a pilot PCMH model called the Chase Ambulatory ICU (ChICU) designed to coordinate care for a subset of our highest risk patients and to improve resident satisfaction with the clinic experience. Enrolling Ms. A in the ChICU meant: 1) Establishment of mutual provider-patient goals, which, in her case, included compliance with the clinic's controlled substance agreement, smoking cessation, and improved diabetes control; 2) Direct access to residents familiar with the patient through a direct-to-provider pager system; 3) Structured monthly team sign-out of patient updates and goals with a core group of known covering resident providers; 4) Completion of a home visit assessment. Two weeks post enrollment, while NS was away on a six-week international health elective, Ms. A was hospitalized for an asthma exacerbation under the care of a medicine resident who had received sign-out, supervised by the faculty preceptor. The same resident then saw her in post-hospital follow up. She has since met the goal of tighter diabetes control with improvement in her A1C from 11 to 8 through frequent structured visits to residents who are familiar with her care. She has been compliant with the controlled substance agreement as evidenced by multiple appropriate urine toxicology screens. Additionally, the home visit helped the care team to appreciate her biopsychosocial complexity as well as to identify further barriers to accomplishing our mutual goals.

DISCUSSION: Patients with low health literacy, complex medical disease and low socioeconomic status may have difficulty navigating a fragmented and complex primary care system. Residency training models focused on inpatient training at the expense of outpatient continuity of care further complicate this fragmentation. Ambulatory ICU models designed to improve continuity of care may improve patient health outcomes for the under-served, medically complex patients served by residency clinics. Although these models traditionally rely heavily on incorporation of non-physician health care providers, we feel the above clinical vignette demonstrates the potential benefits of a structured, resident-driven intervention to improve the quality and continuity of care we provide for patients like Ms. A. Key teaching points: 1) Team-based care can improve outcomes for the complex patients cared for in residency clinics 2) Grassroots, resident-organized teams have the potential to improve outcomes even in the absence of interdisciplinary support and full-time clinic staff.

THE DEVIL IS IN THE (BLOOD SMEAR) DETAILS Naveen Nannapaneni; Adeeb Bulkhi; Marwan Al-Hajeili; Carter Bishop. Wayne State University/Detroit Medical Center, Detroit, MI. (*Tracking ID #1923332*)

LEARNING OBJECTIVE 1: Recognize the utility of a peripheral smear.

LEARNING OBJECTIVE 2: Diagnose thrombotic thrombocytopenic purpura.

CASE: Thrombotic thrombocytopenic purpura (TTP), characterized by low levels of ADAMTS13, abnormal platelet and endothelial activation, microvascular fibrin deposition, and hemolysis, is a disease that carries a high mortality rate. The early recognition of, and emergent plasmapharesis for, TTP results in favorable outcomes. Delay in making the diagnosis can lead to unnecessary investigations, incorrect therapies, prolonged hospitalization and even mortality. A 53 year-old woman with lupus was brought to the ER with progressive confusion, generalized pain, weakness and fatigue going on for 3 days. She was unable to provide further history due to her confusion. On exam her vitals were stable and aside from being confused, had no other abnormality. CBC showed an anemia, 11.2 g/dL, and severe thrombocytopenia 11/ μ L. She had evidence of hemolysis with an elevated LDH 816 U/L and low haptoglobin 10 mg/dL. After being admitted she was transfused with platelets pending a hematology consultation. Hematology suspected a broad differential including immune thrombocytopenia (ITP), plaquenil-induced and hydrochlorothiazide-induced thrombocytopenia and recommended starting corticosteroids while holding the implicated medications. The patient continued to deteriorate without improvement in her platelet count despite receiving platelet transfusions and incurred further mental status decline. Neurology was consulted and suspecting a stroke, performed a CT followed by MRI/MRA of the head, which were all negative for an acute process. Additional evaluation by EEG revealed no epileptiform activity. A second opinion by another hematologist was requested, and after review of the peripheral smear revealed schistocytes, a diagnosis of TTP was made. Immediate daily plasmapharesis was performed and platelet transfusions were discontinued resulting in progressive clinical improvement. Further workup showed a decreased ADAMTS13 activity level, 35 %. She was discharged after plasma exchanges resulted in a return to her baseline mentation and stabilization of hemoglobin and platelet count.

DISCUSSION: The classic presentation of TTP involves the pentad of fever, hemolytic anemia, thrombocytopenia, acute renal failure and neurologic changes. While all five findings are not necessary for diagnosis, whenever a patient presents with microangiopathic hemolytic anemia and thrombocytopenia, the diagnosis of TTP

must be entertained. When included, interventions such as platelet transfusions, and corticosteroids alone, would not be considered as they cause further harm by additional platelet activation and confer no benefit, respectively. Review of a blood smear should be performed as the presence of numerous schistocytes provides rapid, inexpensive, and reliable evidence of TTP. Once diagnosed, the patient should undergo plasmapharesis. As in this case, if the individual problems in TTP are not assessed in a greater constellation there can be inappropriate investigations and therapies which can lead to an unfavorable outcome.

THE DILEMMA OF MANAGEMENT OF CARDIAC TAMPOONADE IN THE PRESENCE OF SEVERE PULMONARY HYPERTENSION: OUR EXPERIENCE Vimalkumar Veerappan Kandasamy; Ajaykumar Kaja; Tammy O. Wichman. Creighton University, Omaha, NE. (*Tracking ID #1939129*)

LEARNING OBJECTIVE 1: To recognize pericardial effusion as a common cause of worsening respiratory status in a patient with pulmonary hypertension.

LEARNING OBJECTIVE 2: To understand the complications of pericardiocentesis in patients with severe pulmonary hypertension presenting with cardiac tamponade.

CASE: A 33 year old Caucasian female with past medical history of pulmonary hypertension (PH) WHO group 1, functional class 3 at baseline, was admitted with complaints of worsening shortness of breath (SOB) and cough for the last 2 weeks. She had SOB at rest with increased oxygen requirements at the time of admission. She was on treprostinil continuous infusion, tadalafil, ambrisentan, digoxin and warfarin for PH. Jugular venous distention and positive Kussmaul sign were noted on examination. The patient went into hypoxic respiratory failure and subsequently intubated. Echocardiogram showed a large pericardial effusion with tamponade physiology with left atrial and ventricular collapse. The right ventricle (RV) was severely dilated and systolic function was severely reduced with RV systolic pressure of 161 mmHg. Pericardiocentesis was performed through a subcostal approach and 40 ml of hemorrhagic fluid aspirated. Pigtail catheter was left in the pericardial cavity and 50–100 ml of pericardial fluid was drained every 4 h. Patient also was started on antibiotics and vasopressors. A total of 2300 cm³ of fluid was aspirated from pericardial cavity with slow intermittent drainage over the next few days. Her clinical condition slowly improved over the week and vasopressors were weaned off. She was slowly diuresed and subsequently extubated and oxygen requirements came down. Although patient improved, her baseline oxygen requirement was higher than pre-admission levels and she was discharged with 2 L oxygen at rest and 4 L oxygen with activity and at night. She was referred to transplant center for lung transplantation.

DISCUSSION: Pulmonary arterial hypertension (PAH) in its advanced stages is complicated by right heart failure (RHF) and pericardial effusion. The optimal treatment of large or hemodynamically significant pericardial effusions in this group is not defined. The prevalence of pericardial effusion can be as high as 54 % and it is one of the predictors for mortality. It is hypothesized that a high PA pressure reduces lymphatic and venous return to a pressure-overloaded RA, leading to the pericardial effusion and eventual tamponade. The full picture of RV failure with low cardiac output and elevated RV filling pressures is typically seen in PH groups 1 and 4. When patients present with worsening RHF, echocardiogram to evaluate for pericardial effusion is an essential component of management. Multiple case reports have been published with various treatment strategies. In a case series of 6 patients by Hemnes et al., both pericardiocentesis and pericardial window placement were associated with significant postprocedural mortality. It was postulated that after removal of pericardial fluid, the already pressure- and volume-overloaded RV can enlarge further, resulting in further septal bowing and subsequently diminishing the LV size leading to worsening left heart filling, left HF, hypotension, and death. Our case report emphasizes the fact that removal of pericardial fluid in small quantities over longer period with adequate hemodynamic support could be a good treatment option for these patients, as it provides time for the right ventricle to adapt to the changing hemodynamics. More experience is needed before concluding this as a standard of care.

THE ELUSIVE DIAGNOSIS OF PULMONARY EMBOLISM; A CASE REPORT Mai Kaga; Leonard Amoruso; Peter Rattner. Beth Israel Medical Center, New York, NY. (*Tracking ID #1897760*)

LEARNING OBJECTIVE 1: Recognize the limitations of using a single imaging modality for diagnosis of pulmonary embolism

LEARNING OBJECTIVE 2: Diagnose pulmonary embolism using imaging modalities in addition to laboratory values and clinical decision making tools

CASE: 35 year old male with history of heroin abuse presented with altered mental status after a witnessed heroin overdose. In the emergency department (ED), after

receiving intravenous naloxone, the patient's mental status improved. The patient disclosed that in the days prior to admission, he had a cough productive of yellow sputum. He had also been experiencing non-radiating chest pain occurring at rest, described as pins and needles for 1 day. He denied fevers, chills, shortness of breath, dysuria, and muscle aches. The patient's initial vitals were remarkable for mild tachycardia to 105; otherwise, he was afebrile and normotensive. Heart sounds were normal with no murmurs, lungs were clear, and there was no evidence of lower extremity edema or JVD. Initial laboratory values were remarkable for elevated creatinine to 2.31, elevated AST/ALT to 585/678 respectively, as well as an elevated troponin of 2.1 with CK/CKMB elevated to 7857/49.3. Initial EKG showed TWI in leads V2-V4 with no old EKG available for comparison. Initial CXR was consistent with a multifocal pneumonia. Bedside TTE, done in the ED, showed left ventricular dysfunction with preserved ejection fraction (EF), as well as right ventricular dilation with possible strain. Concern for a PE led to a ventilation/perfusion (V/Q) scan, the result of which was low to very-low probability for PE. The patient was started on treatment for community acquired pneumonia as well as aspirin, statin and heparin drip for possible NSTEMI. The patient was admitted to telemetry for monitoring. While on the telemetry unit, the patient's troponin continued to rise, peaking at 9.8. The patient was subsequently transferred to the cardiac care unit. An official TTE was performed which showed normal left ventricular size and function with an EF of 65 %. However, there was right ventricular hypokinesis and dilation. The patient underwent a left heart catheterization, which showed no evidence of obstructive disease. During the course of stay, the patient's creatinine improved and a CT Angiogram of the chest was performed, which showed a large segmental pulmonary embolism. The patient was continued on a heparin drip while being bridged to warfarin. He completed his course of antibiotics for community acquired pneumonia and was discharged on warfarin to be followed as an outpatient.

DISCUSSION: The current gold standard for diagnosis of PE remains pulmonary angiography. In more recent years, studies, including PIOPED I/II, have shown both CT angiography as well as V/Q scan in combination with the use of clinic decision making tools, such as modified Well's criteria, as both sensitive and specific. The initial modified Well's score of this patient, 1.5, put the patient into a low risk category. The V/Q scan was very low probability for PE. When using the information put forth by the PIOPED and PIOPED II study, this patient still had a 4 % chance of having a PE, despite the negative V/Q scan results. It is critically important to not abandon the diagnosis of PE, despite having a near normal V/Q scan, in the setting of additional clinical information which may indicate the need for further imaging to diagnose PE.

THE FAÇADE OF FAMILIARITY—A MISSED CASE OF MYXEDEMA COMA

Laura Harrison, Leena Rahmat. Baystate Medical Center, Springfield, MA. (*Tracking ID #1939256*)

LEARNING OBJECTIVE 1: Diagnose myxedema coma, and recognize it as a medical emergency.

LEARNING OBJECTIVE 2: Recognize difficulties created by experiential thinking when diagnosing a rare condition in the geriatric patient.

CASE: An 87 year-old male with a past medical history of advanced dementia, coronary artery disease, and hypertension was admitted from a long-term care (LTC) facility with unresponsiveness in the setting of subacute on chronic cognitive decline. On arrival to the hospital he was hypothermic with a temperature of 96.2 °F and bradycardic with a heart rate of 22. Physical examination was remarkable for lethargy, dry mucus membranes, and Glasgow coma scale (GCS) of 7. Labs were remarkable for serum sodium of 166 and serum creatinine of 3.5. Despite hydration and objective improvements in serum sodium level and renal function, clinically he remained unchanged. A thyroid stimulating hormone (TSH) level was checked on hospital day number 7, which returned at 219. The previous TSH level was normal. Intravenous thyroxine was started and the patient's GCS increased from nine to 12. He was discharged to the LTC facility. Because of significant improvement in cognitive function, comfort goals were instituted and the patient expired 19 days after discharge.

DISCUSSION: Myxedema coma as a diagnosis makes this case unique. As a rare medical emergency, this case provides beneficial teaching points. Such uniqueness creates an environment where experiential thinking perpetuates a poor clinical outcome. This geriatric patient's multiple, and common, co-morbidities further illustrate the downfalls of experiential thinking when clinicians face unique diagnoses in a façade of familiarity.

THE FEBRILE TRAVELER TO INDIA: A CASE OF TYPHOID FEVER

Lucinda B. Leung. UCLA Medical Center, Los Angeles, CA. (*Tracking ID #1900811*)

LEARNING OBJECTIVE 1: Recognize immigrants returning home to visit friends & relatives (VFRs) as a population vulnerable to typhoid fever and target them for immunization.

LEARNING OBJECTIVE 2: Manage typhoid fever when antibiotic-resistant strains of salmonella typhi are involved.

CASE: 41-year-old healthy male presents with fever and malaise, following travel to India one-month prior. The patient emigrated from India as a child, frequently visiting without routine vaccinations. One week after returning, he developed subjective fever, malaise, fatigue and non-bloody diarrhea. He denied abdominal pain, upper respiratory symptoms, cough, headache, palpitations, rash, and sick contacts. His diarrhea had improved but he continued to feel weak and febrile. On admission, he was febrile (Tm 40s), tachycardic (max HR 100 s), normotensive, and hypovolemic on exam. Labs showed mild leukocytosis, hyponatremia and transaminitis. Viral serologies, urine cultures, stool cultures, ova and parasite, hepatitis panel, malaria prep, dengue antibody, HIV, MTB quantifert gold were negative. Blood cultures grew *Salmonella typhi*, resistant to cipro. His antibiotic was narrowed to ceftriaxone for a total 2-week course. Three weeks after antibiotic completion, his fevers returned and his blood cultures again grew *Salmonella*. Liver ultrasound did not reveal any abscess. Echocardiogram did not reveal any valvular vegetation. Tagged WBC scan did not reveal a metastatic source of relapse. He was treated with another 4-weeks of ceftriaxone, then transitioned to 2-additional weeks of azithromycin. He remains afebrile and well to date.

DISCUSSION: Typhoid fever should be suspected in a febrile returning traveler, along with malaria, rickettsial diseases, hepatitis, leptospirosis and dengue. There are 200 to 300 cases of *S. typhi* annually in the United States. However, most cases occur in endemic regions, where there is overcrowding and poor sanitation (e.g., India, Southeast Asia). Typhoid fever is acquired by direct or indirect fecal-oral spread. Since they have less control over their diet, travelers who visit friends and relatives are at increased risk for enteric fever. Typhoid fever is caused by *S. typhi*, following an incubation period of 5 to 21 days. The serotype *S. paratyphi* also causes enteric fever. Humans are the only reservoir for *Salmonella*. Patients present with sustained fever, anorexia, malaise, and vague abdominal discomfort. Diarrhea often appears early in the course and resolves before fever. Physical exam may reveal pulse-temperature dissociation, hepatosplenomegaly or rose spots. Complications include intestinal perforation, encephalopathy, relapse after clinical cure, and asymptomatic chronic carriage. Laboratory findings are nonspecific, such leukocytosis, anemia or transaminitis. *S. typhi* may be isolated in blood, stool, urine, bone marrow and duodenal aspirate cultures. Typhoid fever occurs in unimmunized travelers and 30 % of immunized travelers. Multidrug-resistant *Salmonella* strains are usually found in travelers to the Indian subcontinent. Due to increasing resistance, there has been a shift away from chloramphenicol, ampicillin, and trimethoprim-sulfamethoxazole. For susceptible strains, fluoroquinolones appear to be most effective and used empirically most often. Ceftriaxone (and oral cefixime) and azithromycin are also used for empiric therapy.

THE GREAT MASQUERADE, A BYGONE ACQUAINTANCE OR A PRESENT-DAY FOE?

Maria Fan. University of California, San Francisco, San Francisco, CA. (*Tracking ID #1937836*)

LEARNING OBJECTIVE 1: Perform evidence-based lab and imaging assessment of cognitive impairment and dementia

LEARNING OBJECTIVE 2: Interpret RPR titers to guide clinical suspicion for neurosyphilis

CASE: An 82 year-old African American woman with a history of HTN, hypothyroidism, smoking, and chronic daily alcohol use was seen in clinic for follow-up of cognitive impairment, including difficulty recalling prior clinic conversations with her physician. The patient reported some general "forgetfulness" but declined to provide specifics. She also reported that her father had had syphilis so that she was treated for syphilis at age 9 with penicillin. Her examination was notable for Montreal Cognitive Assessment (MoCA) scores of 17/30 and 16/30 on two separate occasions with a PHQ-9 score of 3/27 suggesting minimal depressive symptoms. The remainder of her physical exam was unremarkable, without any focal neurologic deficits, rigidity, tremor, or gait abnormalities. Laboratory testing revealed normal TSH, B12, and thiamine levels. HIV was negative. RPR testing returned reactive with a titer of reactive undiluted, confirmed with reactive treponemal antibody. After discussion with Infectious Disease, a plan was made to treat the patient for late latent syphilis, with no plan for lumbar puncture to examine for neurosyphilis given the rarity of neurosyphilis in the era of antibiotics, low serum RPR titer, and patient preference.

DISCUSSION: The estimated prevalence of dementia in the United States is 6.5 % for those aged 60 years or greater, with Alzheimer disease representing 60–80 % of cases and vascular dementia 10–20 %. The American Academy of Neurology (AAN) has published guidelines for the laboratory and imaging evaluation of cognitive impairment and

dementia, but what is done in clinical practice remains variable. The current AAN recommendation includes screening for B12 deficiency, hypothyroidism, and structural neuroimaging with either non-contrast CT or MRI. This is in contrast to the prior AAN 1994 practice guidelines that recommended examination of CBC, electrolytes, glucose, BUN/creatinine, folate, B12, thyroid function, and syphilis serology. In 2011, there were 18,576 cases of late and late latent syphilis in the United States (case rate of 6 per 100,000), with Los Angeles County, CA, and Cook County, IL, accounting for the most cases. Given the decline of neurosyphilis cases in the antibiotic era, the AAN now recommends not screening for syphilis unless the patient has a specific risk factor, evidence of prior syphilitic infection, or resides in a high prevalence area. Importantly, studies have found that a serum RPR titer of $\geq 1:32$ highly predicts presence of neurosyphilis, defined as a positive CSF VDRL or CSF pleocytosis, regardless of HIV status or prior syphilis treatment history. A serum RPR titer of $\geq 1:32$ has been suggested as a threshold to consider lumbar puncture to examine for neurosyphilis. In summary, this case reviews the laboratory and imaging evaluation of cognitive impairment and dementia in addition to illustrating the complexity of syphilis serology in considering neurosyphilis.

THE INCREDIBLE FUSS OVER ATYPICAL HUS Anita Bhagavath; David Chun; Jason Filopei; Gina Elhammady; Andrew Bohmert. Beth Israel Medical Center, New York, NY. (*Tracking ID #1928693*)

LEARNING OBJECTIVE 1: Recognize the clinical features of atypical hemolytic uremic syndrome.

LEARNING OBJECTIVE 2: Recognize the differences between typical HUS and atypical HUS.

CASE: 60yo F with PMhx of Hepatitis C presented with shortness of breath for 2 days, associated with chest tightness and lightheadedness. Further questioning revealed she had 2 days of bloody stools, hematuria, and minor nose bleeds. Physical examination was remarkable for dried blood in the nares, pale conjunctiva, and a flow murmur. Rectal exam showed brown stool. Admission labs revealed acute on chronic kidney disease, new normocytic anemia, and mild thrombocytopenia (Creat 4.75 g/dL, baseline 1.55, Hgb 7.8 g/dL, baseline 11.9, Plt count 130 K/uL, baseline 237, all 1 month prior). Stool sample was occult positive. Urinalysis was yellow, with large blood (>182 RBCs). Anemia work up showed schistocytes on peripheral smear, lactate dehydrogenase (LDH) 999, haptoglobin 16, and normal bilirubins. C3 was elevated (250 mg/dL) and C4 was low (3 mg/dL). The patient underwent emergent plasmapheresis and hemodialysis, with marked improvement in clinical status and laboratory abnormalities (Hgb 10.8, LDH 498, Plt 206, Creat 2.98). Stool cultures were negative and ADAMTS13 activity was normal, ruling out toxin-mediated hemolytic uremic syndrome and thrombotic thrombocytopenic purpura, respectively. Renal biopsy findings were consistent with HUS and a final diagnosis of atypical HUS (aHUS) was made. She was discharged with a plan to continue hemodialysis and begin outpatient eculizimab therapy.

DISCUSSION: HUS is characterized by the triad of hemolytic anemia, severe thrombocytopenia, and renal impairment. Commonly this is secondary to Shiga toxin-producing enteric infections and presents as bloody diarrhea. In contrast, aHUS is both toxin and diarrhea negative, and is secondary to dysregulation of the alternate complement pathway. Our case of aHUS was unique because it presented with bloody diarrhea, only mild thrombocytopenia, and elevated rather than decreased C3 levels. These atypical presentations can result in delayed diagnosis and worsened outcomes. Plasmapheresis is the first-line therapy for aHUS and early initiation leads to better outcomes. Response is monitored by normalization of platelets, hemoglobin and LDH. Recently, a better understanding of the pathophysiology behind aHUS has led to the emergence of eculizimab, a humanized anti-C5 monoclonal antibody. This drug inhibits the critical steps in the alternative complement pathway and is currently being evaluated in clinical trials. This new treatment option is changing the therapeutic approach to aHUS. One should recognize that aHUS can present with or without bloody diarrhea and the hallmark laboratory data may not always follow the classic pattern. This is important as early intervention with plasmapheresis and more cutting edge therapy such as eculizimab may be critical to improved outcomes.

THE INDELIBLE DIRECTIVE: A CASE SERIES REPORT OF PATIENTS WITH DNR TATTOOS Yevgeniy Mikiyanskiy; Sagar Patil; Paul Leis; Jonah Feldman. Winthrop University Hospital, Mineola, NY. (*Tracking ID #1937593*)

LEARNING OBJECTIVE 1: To help guide treatment decisions for patients with DNR tattoos who may not be able to communicate their wishes.

CASE: Tattooing as a form of artistic expression remains as popular as ever, and some people are now choosing their ink based upon their attitudes towards health care. A 69-year-old widowed man with "Do Not Resuscitate" tattooed on his left

forearm and past medical history of lung cancer presented to our emergency room with shortness of breath and fever. He was found to be in acute respiratory failure from pneumonia. Though he had difficulty speaking, he was able to communicate that he wished full resuscitation efforts to be made, including intubation, if needed. Mechanical ventilation as well as appropriate treatment was initiated, which led to a complete recovery. He explained that the tattoo represented his frustration with the health care system after losing his wife to cancer several years prior, but his attitude about health care changed after establishing a rewarding doctor-patient relationship with a new primary care physician. He was healthy when the tattoo was inked, and he never intended for it to be taken as an advance directive.

DISCUSSION: To help guide treatment decisions for future patients who may not be able to communicate their wishes, we searched Pubmed and Google scholar for articles containing the phrase "do not resuscitate" and the word "tattoo." Review of these articles revealed four previously published case reports, which formed a series of five cases when added to our own. Based on these reports, we identified three reasons why a DNR tattoo should not be actionable in clinical practice. 1) A tattoo inked years ago may not be an accurate reflection of a patient's current wishes. 2) DNR tattoos are ambiguous and are often intended to make a public statement unrelated to decisions about resuscitation. 3) DNR tattoos are not legally binding. While the third reason reflects a technical concern, the first two give insight into the true feelings of patients who get this type of tattoo. In our case series, patients with tattoos had a change in preference regarding resuscitation status in 2/5 cases. The meaning behind the tattoo did not coincide with specific decisions about resuscitation in 3/5 cases. In total, we found that tattoos did not accurately reflect patient resuscitation preferences in 4/5 cases. From this first known case series of patients with DNR tattoos, we conclude that clinicians should strongly consider resuscitating patients unless they have appropriate documentation. Tattoos, however, should be used as a starting point for conversations regarding preferences for care. In our case, this discussion led to a narrative that enriched the relationship between the patient and his healthcare providers.

THE MYSTERIOUS GREEN URINE! Venu M. Ganipisetty; Pratyusha Bollimunta; Sathish Kumar Krishnan; Malav P. Parikh; Harvey Friedman. presence saint francis, Evanston, IL. (*Tracking ID #1923585*)

LEARNING OBJECTIVE 1: 1) Recognize that Propofol administration can be associated with green urine in patients.

LEARNING OBJECTIVE 2: 2) Recognize that this finding is benign and does not cause harm to the patient. Discontinuing the medication will normalize the urine color in few hours and will establish the diagnosis.

CASE: A 44-year-old African-American male with no known past medical history, presented to our Emergency department with blunt head trauma resulting in intracranial hemorrhage. Upon arrival, he was agitated, minimally responding to verbal stimuli, and was intubated emergently in the ER and later transferred to the ICU for close observation. He was started on a Propofol and Fentanyl infusions for sedation and analgesia. Sedation vacation was tried each day during the hospital course, however the patient became agitated, restless, and hypertensive upon weaning. He continued to require propofol and fentanyl at high doses. On day 10 of admission, we observed that his urine in the Foley bag was green. At that time, his labs were normal except for elevated alkaline phosphatase 177 and serum albumin 2.9. His medications at this time were Lisinopril, Amlodipine, Unasyn (for facial injuries), and Dilantin. Cultures were negative for bacterial growth. Ultimately, Propofol was stopped and patient was switched to an Ativan drip. We monitored the urine color, which changed back to yellow within 6 h. No further work up was done.

DISCUSSION: Propofol is a commonly used sedative in critical care settings. Green urine color with propofol is a benign and rarely reported finding. To date, only 13 cases are reported in the literature. It has been proposed that green color occurs due to the presence of metabolites in urine. Propofol is metabolized in the liver by glucuronide conjugation and excreted in urine predominantly as the 1-glucuronide, 4-glucuronide, and 4-sulfate conjugates of 2,6-diisopropyl-1,4 quinol which imparts green color to urine. Urine alkalization increases the formation of these metabolites. A second proposed potential mechanism is entero-hepatic circulation failure due gallbladder hypomotility and extra-hepatic glucuronidation in the kidneys, which might be the cause of green urine in our patient. Other common causes for green urine include pseudomonas infection (Pyocyanin pigment), hartnup disease, indicanuria, ingestion of triamterene, amitriptyline, indometacin, methocarbamol, promethazine, cimetidine, food coloring, listerine mouthwash, clorets mints, indigo dyes, and methylene blue. All these were excluded in our patient. The temporal relationship of normalization of urine color upon discontinuing propofol indicates it is the most likely cause of this finding. Presence of propofol metabolites in urine is benign and does not affect kidney function or cause harm to the patient. Although this finding is benign, it may cause unnecessary apprehension in physicians and family members.

Notably, in an informal survey of over 30 Anesthesiologists, only one was aware that propofol could cause green urine. This case illustrates that an awareness of this benign finding is important and may prevent unnecessary testing. We were able to avoid all unnecessary further workup in this patient while providing reassurance to the patient's family members.

THE OUTPATIENT MANAGEMENT OF KETOSIS-PRONE DIABETES AT BELLEVUE HOSPITAL Arnab K. Ghosh; Jamie Osman; Natalie K. Levy. NYU, New York, NY. (*Tracking ID #1920760*)

LEARNING OBJECTIVE 1: 1) Recognize the epidemiology and classification of Flatbush/Ketosis-Prone Diabetes Mellitus and its common presentation as diabetic ketoacidosis.

LEARNING OBJECTIVE 2: 2) Recognize the need to carefully monitor glucose levels in ketosis-prone diabetic patients, who are at risk for hypoglycemia to prevent hypoglycemia.

CASE: A 53YO Mexican previously well male was admitted with a week-long history of polyuria, polydipsia, dry mouth, and a 30 lb weight loss over the past 2 weeks. He denied any personal or family history of diabetes mellitus. On examination he was clinically dehydrated. His labs were significant for K 5.5 mmol/L, HCO₃ 21 mmol/L, chloride 88 mmol/L glucose 1190 mg/dL, anion gap of 22, urinalysis showing ketones and glucose. Venous blood gas pH was 7.284. The patient was diagnosed with diabetic ketoacidosis and treated with intravenous fluids, potassium supplementation and insulin therapy. His symptoms resolved without incident. No precipitating factor was found. He was discharged home on glargine 10 units at night and metformin 1000 mg twice a day. The patient was seen in clinic. His glutamic acid decarboxylase (GAD) antibody and islet cell antibody were negative, fasting C-peptide was 2.23 ng/mL (N: 0.8–3.1 ng/mL) and HbA1c 15.8 %. He was only taking 6 units of glargine for unclear reasons. Based on his home blood glucose readings, his glargin dose was increased to 20 units nightly over these first two visits. For 2 subsequent visits over the next 5 weeks this insulin dose, plus metformin, led to controlled fasting blood glucose. The patient was lost to follow up for the next 2 months. When he returned to clinic 4 months after his initial discharge, he had ceased taking his insulin and metformin, owing to symptoms of hypoglycemia. Repeat HbA1c was 7.1 %. Because his fingerstick glucose remained elevated, the patient was restarted on metformin.

DISCUSSION: This case represents a case of a patient with Ketosis-Prone Diabetes (KPD) initially presenting with DKA. In the literature, KPD has been noted in the Hispanic and African-American populations, the diagnosis occurring in the fourth or fifth decade of life. Most patients diagnosed with KPD tend to be obese, and 80 % have a family history of type 2 diabetes mellitus. To place a KPD patient into the AB classification system, they need to be tested for both autoantibodies and beta cell reserve. Our patient was GAD and Islet Ab negative. His fasting C-Peptide level was normal, placing him in the A-B+ category, the most common category for new diabetes presenting in DKA. Patients with a new diagnosis of DM in DKA have a varied post discharge course. Some will need lifelong insulin. Others will have recovery of beta cell function and be able to come off of their insulin. A classification of A-B+ is associated with the highest likelihood of achieving insulin independence. Smiley et al. recommend KPD patients be followed every 2 weeks for the first 2 months for insulin adjustment. If found to have fasting blood glucose values of <130 for 2 weeks (or if there is any hypoglycemia) then tapering should occur, decreasing the dose by 25 % at each visit. In our patient's case, his fasting glucose values <130 at weeks 4, 5, and 7 should have prompted a tapering of his glargin. When he returned ~4 months after hospital discharge, he had tapered his insulin off himself.

THE PERFECT LIPODYSTROPHY STORM Victoria Gutgarts^{1,2}; Ewa M. Rakowski^{1,2}; Bettina Fries^{1,2}. ¹Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine, Bronx, NY. (*Tracking ID #1938598*)

LEARNING OBJECTIVE 1: Define and identify the causes of acquired lipodystrophy.

LEARNING OBJECTIVE 2: Discuss the complications and management of lipodystrophy.

CASE: A 45 year-old woman with uncontrolled diabetes, hypertriglyceridemia, and human immunodeficiency virus (HIV) on antiretroviral medication presented with 1 day of worsening epigastric abdominal pain. The patient described the pain as constant, severe and radiating throughout the abdomen, with associated nausea and vomiting. Vital signs were notable for a temperature of 101 F. Abdomen was mildly distended with guarding and epigastric tenderness. Murphy's sign was negative.

Eruptive xanthomas were present at the elbows bilaterally as well as loss of subcutaneous fat over the arms, legs, and buttocks. Initial laboratory values were significant for a hemoglobin A1c of 12, lipase of 11,794, amylase of 1,857, and fasting triglycerides of 8,046. Patient was managed for acute pancreatitis secondary to hypertriglyceridemia. She was started on intravenous fluids and insulin. An apolipoprotein B level of 265 (normal 49–103) supported an underlying familial combined hyperlipidemia. Additionally, the patient was diagnosed with acquired HIV associated lipodystrophy.

DISCUSSION: The term lipodystrophy was derived from the Greek language, and has the literal translation of fat ill nourishment. This term is often used to describe a collective group of disorders characterized by degeneration of complete or partial adipose tissue. The two main types of lipodystrophy are congenital and acquired. The congenital type is autosomal recessive, and results from mutations in genes that interfere with lipid synthesis and differentiation. Acquired lipodystrophies are hypothesized to result from infections, medications, and autoimmune disorders. HIV is a common infection that can cause acquired lipodystrophy. In specific, it is the treatment with protease inhibitors that may impair differentiation of adipocytes and lead to apoptosis of peripheral adipose tissue. The mechanism for this is suggested by a homology in the catalytic site of HIV protease to proteins involved in lipid metabolism. Circulating lipids are then free to deposit in central tissues such as the abdomen and breasts. Other types of acquired lipodystrophies are named based on the amount of affected peripheral tissue. As an example, acquired generalized lipodystrophy, or Lawrence Syndrome, involves a generalized loss of fat, whereas, acquired partial lipodystrophy, or Barrera-Simons syndrome, spares the abdomen and lower extremities. A localized lipodystrophy can also occur, often from subcutaneous injection of drugs such as insulin. The diagnosis of lipodystrophy is essential to prevent the many complications that can occur. The destruction of adipose tissue results in a decreased production of the leptin hormone, which normally acts at the hypothalamus to inhibit appetite. Loss of this hormone results in hunger and increased caloric intake. Increased calories have few adipocytes to deposit in, resulting in ectopic lipid deposition and muscle hypertrophy and hepatic steatosis. Elevated triglycerides in specific, can lead to acute pancreatitis. Patients with conditions like familial hyperlipidemias are at a higher risk, given the increased triglycerides at baseline. A lipid profile can be checked in suspected cases, followed by apolipoprotein levels. Excess lipids can lead to other complications like insulin resistance and eventually diabetes. Insulin resistance can also affect the reproductive system, leading to polycystic ovarian syndrome and issues with infertility. Management of lipodystrophy begins with lowering the primary lipid abnormality. Statins and fibrates are often used to lower elevated LDL and triglycerides, respectively. Thiazolidinedione and metformin are two additional agents which act to improve target cell's response to insulin and reduce fat atrophy. Switching to different protease inhibitors has also been suggested in patients with HIV lipodystrophy. Studies have also shown that leptin replacement therapy with analogs like metreleptin has reduced hyperglycemia, hypertriglyceridemia, and decreased liver size. Along with pharmacological management, preventative therapies like diet and exercise can help reduce complications even in the setting of underlying lipid disorders and acquired diseases. Managing patients with lipodystrophy can be challenging, especially when patients have underlying conditions like diabetes, familial hyperlipidemia, and HIV. It is therefore essential to diagnose lipodystrophy early and utilize a multi-modal approach to treatment to prevent future complications of the disease.

THE PERFECT STORM: A FEBRILE ANAPHYLACTOID REACTION Jason P. Williams¹; William Reid¹; Raffi Tachdjian². ¹UCLA, Marina del Rey, CA; ²UCLA, Los Angeles, CA. (*Tracking ID #1927138*)

LEARNING OBJECTIVE 1: Distinguish anaphylactoid reactions from IgE mediated anaphylaxis.

LEARNING OBJECTIVE 2: Recognize a novel association of mast cell degranulation and fever in the setting of granulocyte colony stimulating factor

CASE: A 30 year old female with BRCA-1 and triple negative bilateral breast cancer presented with a fever and rash. She previously had a bilateral mastectomy, radiation, and recently completed her third cycle of docetaxel and cyclophosphamide 9 days prior to admission. Eight days prior, she received pegylated granulocyte colony stimulating factor (G-CSF). Cephalexin was prescribed over the phone for bilateral arm swelling that turned out to be lymphedema. She tolerated her first dose, but woke 4 h after the second dose of cephalexin with a diffuse pruritic rash. In the ER, her temperature was 38.0, heart rate 132 and blood pressure 86/47. Her extremities and torso exhibited erythematous, well circumscribed, raised plaques with central pallor consistent with urticaria (image available for presentation). There was no stridor or wheezing. Four hours later she developed angioedema of her lips, sparing her tongue. These symptoms quickly resolved with IM epinephrine, IV fluids, diphenhydramine,

and methylprednisolone. She had a recurrence of her angioedema on hospital day 2 that again improved with IM epinephrine. Prior to corticosteroids, the WBC was 30,000 with 92 % neutrophils. Without any significant course of antimicrobials, the WBC normalized by hospital day 3. The patient spiked nightly fevers that were associated with flares of urticaria until hospital day 4. Penicillin skin testing done at the bedside was negative. An infectious work up was negative including repeated blood and urine cultures, stool C. Difficile PCR, serum CMV PCR, monospot, and nasal respiratory viral PCR. CT of the chest, abdomen and pelvis was unrevealing other than pericholecystic fluid with a normal HIDA scan. Ultrasound of the four extremities was negative for DVT. The patient was discharged on hospital day 5. She has since completed several more cycles of chemotherapy without further complications.

DISCUSSION: The differential for a rash and fever is broad. Infectious etiologies are possible, though her extensive work up was negative. Her tumor burden, if any, is too minimal to account for such profound symptoms. Reintroduction of her chemo has been uneventful. The antecedent antibiotic prompts consideration of a drug reaction. Drug Reaction and Eosinophilia with Systemic Symptoms (DRESS), Serum Sickness, and Stevens-Johnson can present with fever and rash, but none develop this rapidly nor do they account for her angioedema. The patient's urticaria, angioedema and hypotension meet criteria for anaphylaxis and she responded appropriately to treatment. Anaphylaxis is an immediate hypersensitivity reaction, so the 10 h delay in symptom onset argues against an IgE mediated process. Anaphylactoid reactions are pseudoallergies that are clinically identical to anaphylaxis except anaphylactoid reactions can have a delayed presentation following drug exposure. This pseudoallergy results from direct stimulation of mast cells without cross linking to IgE. This explains why penicillin skin testing is negative in anaphylactoid reactions and positive in anaphylaxis. In the acute setting, anaphylaxis and anaphylactoid reactions are treated identically. Unlike IgE mediated reactions, pseudoallergies do not always preclude reexposure to the offending drug. One cases series found that if a reaction to a cephalosporin occurred greater than 1 h after exposure and the patient had negative skin testing, they completely tolerated reexposure to the drug. Neither anaphylactic nor anaphylactoid reactions result in fever or neutrophilia. However, the recurrent fever and simultaneous flares of urticaria suggest that they were linked. She did receive G-CSF which is associated with fever, neutrophilia, and a heightened neutrophil functionality. In vitro, these G-CSF primed neutrophils have been shown to release significant quantities of IL-6 when exposed to TNF-alpha. Mast cells are a significant source of TNF-alpha. Together, TNF-alpha and IL-6 produce fever. This novel clinical combination of mast cell degranulation stimulating G-CSF primed neutrophils appears to be the perfect cytokine storm for an anaphylactoid induced fever. Further study into the exact mechanism and biomarkers are warranted.

THE SHOUT OF A MURMUR: A DRAMATIC PRESENTATION OF MITRAL REGURGITATION Mara E. Murray Horwitz; Jennifer Siegel. Boston Medical Center, Boston, MA. (*Tracking ID #1939427*)

LEARNING OBJECTIVE 1: Review the sequelae of severe untreated mitral regurgitation (MR), including right heart failure, pulmonary hypertension, and atrial fibrillation;

LEARNING OBJECTIVE 2: Appreciate key physical exam findings associated with MR, and understand how the diagnosis of MR is made.

CASE: A 67 year old woman presented with altered mental status and leg pain. She was unable to provide further history. Past medical history was inferred from medications in her purse as significant for congestive heart failure (pill bottles of Furosemide 80 mg twice daily, Metoprolol 25 mg twice daily, and Lisinopril 5 mg daily), and atrial fibrillation (pill bottle of Pradaxa 150 mg daily). In the ED, her temperature was 96.9, blood pressure was 121/85, pulse was 120, respiratory rate was 18, and oxygen saturation was 100 % on room air. Exam was notable for somnolence, irregularly irregular cardiac rhythm, IV/VI holosystolic murmur heard throughout the precordium and posterior chest, and 3+ pitting edema to the sacrum. Laboratory studies were notable for a white blood cell count of 8.3, BUN of 41, creatinine of 2.01, alkaline phosphatase of 200, mild transaminitis, troponin of 0.039, BNP of 1632, and lactate of 2.3. Her EKG confirmed atrial fibrillation. A CT scan of her head was unremarkable. Chest x-ray showed pulmonary vascular congestion. She was admitted to the Medicine service for acute and chronic heart failure of unknown etiology. Upon arrival to the inpatient floor, a diagnostic trans-thoracic echocardiogram was performed. It revealed redundant mitral leaflets with severe mitral regurgitation (MR) causing pulmonary vein flow reversal, severe tricuspid regurgitation, inferior vena cava dilation, and hepatic vein flow reversal. She had a left ventricular ejection fraction of 50–55 %, mild right ventricular enlargement, and severe bilateral atrial enlargement. Her hospital course consisted of a 40-pound diuresis, with subsequent normalization of her renal and liver function tests and improvement in her mental status. She was considered for mitral valve repair or replacement, but unfortunately declined pre-surgical evaluation and left against medical advice.

DISCUSSION: This patient's presentation illustrates the sequelae of severe mitral regurgitation (MR), while her hospital course reminds us of the classic physical exam findings and diagnostic studies for this condition. As seen here, severe MR can cause congestive heart failure by way of pulmonary hypertension, tricuspid regurgitation, and right heart failure. Resultant venous congestion can cause multi-organ damage, such as the altered mental status, acute kidney injury, and hepatic congestion seen in this patient. Long-standing MR with atrial enlargement may precipitate atrial fibrillation, which in retrospect was the first diagnostic clue toward her diagnosis. Several classic physical exam findings of MR were found in this patient. First, a holosystolic ejection murmur radiating to the apex, axilla, or back is almost always present. A wide split S2 and an S3 gallop may also be heard. When MR leads to right heart failure, as illustrated in this case, the systemic signs of congestive heart failure (dyspnea, lower extremity edema, encephalopathy, and congestive hepatopathy) will ensue. Echocardiogram makes the diagnosis of MR, in which severity is based on valve width, area, regurgitant volume, and presence of flow reversal. Of note, there is little correlation between the loudness of the murmur and MR severity, although grade I-II murmurs are rarely severe. The chambers of the heart are also affected. Left ventricular enlargement is common with severe MR, while left atrial enlargement is common with chronic MR. In this patient, severe MR was diagnosed by flow reversal. Left ventricular and atrial enlargement seen on her echocardiogram suggested that her MR had been both severe and chronic, respectively. This woman paints a dramatic portrait of severe, chronic, and untreated MR. The diagnosis was suggested in every element of her past medical history, physical exam, and laboratory studies, and was ultimately confirmed by echocardiogram.

THE SIMPLEST ANSWER IS THE BEST ANSWER Erica Altschul; Allison Selby. Lenox Hill Hospital, New York, NY. (*Tracking ID #1933727*)

LEARNING OBJECTIVE 1: Formulate differential diagnosis of bradycardia

LEARNING OBJECTIVE 2: Recognize the importance of medication side effects in the differential diagnosis of bradycardia

CASE: This 68 year old man with a history of hypertension, ESRD on hemodialysis, and glaucoma was referred to Lenox Hill Hospital in New York, NY by his dialysis center for asymptomatic bradycardia (around 30 bpm) for 1 h. His home medications included amlodipine, carvedilol, allopurinol, omeprazole, ASA, dorzolamide/timolol eye drops, brimonidine tartrate eye drops, and travoprost eye drops. The patient's past surgical, family, and social histories were not significant. Review of systems was notable for chronic and unchanged dyspnea on exertion as well as exertional chest pain. In the ED, his heart rate was 32 bpm, blood pressure 105/60, respiratory rate 18, and saturation of 98 % on room air. Physical exam was remarkable for bradycardia, 2+ pitting edema bilaterally, and a left arm AV fistula. An EKG demonstrated a junctional rhythm at 35 bpm. An echocardiogram demonstrated mild left ventricular hypertrophy with an EF of 50–55 %. The patient was admitted to telemetry for monitoring. His home medications were continued except amlodipine and carvedilol secondary to hypotension and bradycardia, respectively. Due to persistent bradycardia, permanent pacemaker placement was considered but not done due to right subclavian vein occlusion and his AV fistula precluded left subclavian access. The patient was considered a poor surgical candidate for an epicardial pacemaker given his comorbidities. The patient's timolol/dorzolamide eye drops were discontinued with the belief they could have been causing his bradycardia, after which his heart rate improved to greater than 60 bpm. The patient was discharged on alternative glaucoma therapy as recommended by ophthalmology (Dimonidine and Dorzolamide).

DISCUSSION: Bradycardia is defined as a heart rate less than 60 beats per minute. When a patient presents with bradycardia, it is important to consider the possible causes; including, cardiac disease including sick sinus syndrome, high degree AV block, endocarditis, and myocardial infarction; electrolyte imbalances; hypothermia; and hypoglycemia. Medication side effects are often overlooked, with common culprits including centrally acting alpha-2 agonists, cholinesterase inhibitors, calcium antagonists, digitalis, and beta-blockers. Studies have shown that ophthalmic Timolol is similar to intravenous Timolol having comparable systemic bioavailability, plasma kinetics, and cardiopulmonary effects, mainly bradycardia. This effect on the heart rate is even more noticeable during exercise. The impact on blood pressure is considered less significant, likely because of the compensatory increase in systemic vascular resistance due to the lowered heart rate. Bradycardia due to Timolol has been documented in many case studies and is associated with syncope, especially in the older population and patients with pre-existing cardiovascular morbidity. It is important to look closely at medications as they can be a reversible cause to a patient's chief complaint

THE TRIPLE GI THREAT OF CMV: A CASE OF CMV ESOPHAGITIS, HEPATITIS AND PANCREATITIS IN NEWLY DIAGNOSED HIV Kendrick B. Gwynn¹; Ameeta Kalokhe²; Robin Klein¹. ¹Emory University School of Medicine, Atlanta, GA; ²Emory University School of Medicine, Atlanta, GA. (*Tracking ID #1938187*)

LEARNING OBJECTIVE 1: Recognize the less common gastrointestinal manifestations of cytomegalovirus disease in HIV-positive patients

CASE: A 41 year old male to female transgender with no significant past medical history presents with 4 weeks of odynophagia exacerbated with food and acidic liquids. She denied use of alcohol and illicit substances, but noted taking NSAIDs to relieve the pain. Review of systems was notable for anorexia, weight loss and night sweats. Exam revealed two palpable anterior cervical lymph nodes. No oral lesions or thrush was noted and abdominal exam was benign. Labs were notable for AST 786 U/L, ALT 218 U/L, Alkaline phosphatase 492 U/L, total bilirubin 4.1 mg/dL with direct component 2.9 mg/dL. Abdominal ultrasound showed no gallstones and patent hepatic veins. Acetaminophen level was negative. HIV ELISA and Western Blot were positive. CD4 was 22/mCL and viral load log 6.08 copies/mL. Endoscopy showed chronic active esophagitis, a 5 cm proximal ulcer and chronic inactive gastritis. Biopsies of the ulcer were taken, but while awaiting pathology results, the patient developed severe epigastric abdominal pain. CT scan showed pancreatitis but no gallstones. Lipase, AST, and ALT were 1750 U/L, 1800 U/L and 360 U/L, respectively. MRCP showed no pancreatic masses or evidence of obstruction. Triglyceride level was mildly elevated at 247 mg/dL. Further infectious workup was unrevealing including blood cultures, AFB blood cultures, tuberculin skin test, histoplasma antigen, Bartonella henslae antibody, Mycoplasma antibody, cryptococcal antigen, and viral hepatitis serologies. Eight days into the hospital course, pathology results of the esophageal biopsy returned, demonstrating an absence of cytopathologic changes typically seen with viral esophagitis, but immunohistochemical staining revealed CMV. CMV IgG was positive, IgM was negative and CMV-PCR was 1438 copies/mL. Dilated fundoscopic exam was without evidence of CMV retinitis. Induction therapy with IV ganciclovir renally dosed followed by oral valganciclovir 900 mg twice daily was initiated. Abdominal pain resolved 5 days into induction therapy and liver enzymes normalized. The patient was discharged to complete 21 days of induction therapy, followed by valganciclovir secondary prophylaxis, and was linked to comprehensive outpatient HIV care.

DISCUSSION: Cytomegalovirus infection can cause a variety of infections in immune compromised patients including retinitis, encephalitis, and esophagitis. A retrospective study found that a third of patients co-infected with CMV and AIDS manifested gastrointestinal disease. Nearly half of patients with gastrointestinal disease have esophagitis and 10 % have pancreas or liver involvement. Degree of CMV viremia by PCR does not necessarily indicate the presence of end-organ damage and cannot be solely used to diagnose end-organ disease. Esophagitis can also be due to other infections including HSV, HIV-associated aphthous ulcer, Candida, or tuberculosis but were all negative in this case. CMV remains the most common viral cause of esophagitis in immunocompromised patients. Literature review found seven cases of pathologically evident CMV pancreatitis, three of those presenting with clinical pancreatitis and one of which was associated with HIV, the others in post renal transplant patients. Pancreatic involvement by CMV has been reported in autopsies even without clinically observed pancreatitis. CMV has also been implicated as a cause of acute granulomatous hepatitis. Studies have shown higher rates of CMV in perinatally HIV infected children presenting with hepatitis. CMV hepatitis has been reported in the setting of acute HIV infection. Our case represents a rare presentation of CMV infection manifesting as concomitant esophagitis, pancreatitis and hepatitis in a newly diagnosed HIV infected patient. Physicians should be aware of the less common gastrointestinal manifestations of CMV infection in HIV-infected patients.

THE UNUSUAL SUSPECT: PARANEOPLASTIC MONONEURITIS MULTIPLEX Jane J. Lee¹; Gaetan Sgro². ¹University of Pittsburgh Medical Center, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA. (Tracking ID #1936766)

LEARNING OBJECTIVE 1: Include paraneoplastic syndrome in the differential diagnosis of mononeuritis multiplex.

LEARNING OBJECTIVE 2: Recognize that mononeuritis multiplex can precede any other manifestation of a primary malignancy.

CASE: A 44 year old Caucasian man presents with acute lower back pain for 2 days. He has a history of a recent left orchitis and epididymitis treated with antibiotics, and multiple cranial nerve palsies and mononeuritis multiplex of unknown etiology that had persisted for 3 years. His previous symptoms had included left sixth and third cranial nerve palsies and unilateral, intermittent limb pain. He had previously undergone an extensive work up for rheumatologic, metabolic, toxic, and neoplastic etiologies, which was negative. Cerebrospinal fluid analyses were normal. Electromyography showed a right ulnar nerve focal neuropathy. A sural nerve and muscle biopsy showed mild axonal degeneration and chronic neurogenic changes, respectively. Numerous MRI and CT scans of his head and spine were unremarkable. A

whole body gallium 67 imaging study was negative. Anti-hu antibody was negative. His neurologic symptoms were treated with intermittent steroids. On presentation, his exam was notable for anisocoria (left pupil larger than the right) with impaired adduction of the left eye, decreased light touch sensation on both sides of the forehead, and 3/5 strength in right hip flexion and ankle dorsiflexion. He had a palpable, non-tender left testicular nodule. Labs were only notable for new thrombocytopenia, with a platelet count of 37,000. A spine MRI with contrast showed new enhancement of the conus medullaris that was concerning for leptomeningeal involvement of a malignancy. A brain MRI now demonstrated a new left cavernous sinus mass. He underwent a bone marrow biopsy, which revealed a diffuse large B-cell lymphoma. He also underwent a left orchectomy, and pathology showed a primary testicular lymphoma. PET/CT scan showed scattered lymph nodes as well as lesions in the spleen, thyroid, adrenal gland, and skeleton that were hypermetabolic and consistent with metastatic disease. The final diagnosis was primary testicular lymphoma, diffuse large B-cell type, with CNS and bone marrow involvement, and paraneoplastic mononeuritis multiplex. His neurologic symptoms improved dramatically after initiation of chemotherapy.

DISCUSSION: Involvement of the peripheral nervous system occurs in 5 % of lymphoma cases, mostly in non-Hodgkin lymphomas. Neuropathy in lymphomas is either a result of neurolymphomatosis (i.e. direct invasion of lymphoma cells into the peripheral nervous system, which is diagnosed pathologically or by positive signals on PET imaging) or a paraneoplastic syndrome, which is much less common. This case illustrates mononeuritis multiplex as the initial presentation of lymphoma, preceding the lymphoma diagnosis by several years. Malignancy was included in the differential during his prior work up, but was never proven until this presentation. Ultimately, his mononeuritis multiplex was attributed to a paraneoplastic disorder based on nerve biopsies and PET scans that failed to show direct lymphoma involvement of the peripheral nerves, as well as the fact that his symptoms resolved after chemotherapy. References 1. Hughes RA, Britton T, and Richards M. Effects of lymphoma on the peripheral nervous system. J R Soc Med. 1994 September; 87(9): 526–530. 2. Tomita M, et al. Clinicopathological features of neuropathy associated with Lymphoma. Brain 2013; 136; 2563–2578

THE UPSURGE OF EOSINOPHILS Paras Karmacharya¹; Madan R. Aryal¹; Carol Kalathas¹; Michael Goonewardene¹; Ranjan Pathak¹; Pragya Shrestha²; Supriya Shrestha Tamrakar³; Anthony Donato¹. ¹Reading Health System, West Reading, PA; ²Nanjing Medical University, Nanjing, China; ³Guangxi Medical University, Guangxi, China. (Tracking ID #1935129)

LEARNING OBJECTIVE 1: Recognize Hypereosinophilic Syndrome (HES) as an important but uncommon cause of extreme elevation of eosinophil counts, that can result in significant end-organ damage if not treated.

LEARNING OBJECTIVE 2: Recognize glucocorticoid as the first line treatment to reduce the number of tissue eosinophils.

CASE: A 69-year-old female presented with low grade fever, dyspnea on exertion, fatigue and confusion for 1 week. She denied history of rash, recent travel or asthma in the past. On exam, the patient appeared confused but without focal neurological deficits. She had a high white cell count of 25.7c/mm³ with 59 % eosinophils and absolute eosinophil count of 15,000c/mm³. Electrocardiogram showed some t-wave inversions on anterolateral leads, along with troponin level - 15 ng/ml, BNP - 1028 pg/ml. Patient had a creatinine of 2.49 mg/dl (baseline: 0.96 mg/dl, 2 months prior) with urinalysis showing many eosinophils. An extensive workup was performed to rule out secondary causes of eosinophilia, including stool studies for ova and parasites and serology for helminthic infections, autoimmune vasculitis, and collagen vascular disease, which all proved negative. Bone marrow aspiration and biopsy revealed marked eosinophilia (40 %), without any evidence of leukemia or lymphoma. Fluorescence in situ hybridization (FISH) analysis for genetic mutations of FIP1L1-PDGFR α and BCR/Abl were negative. Treatment with oral prednisone led to dramatic lowering of white cell counts and eosinophils with resolution of all symptoms. Her prednisone was slowly tapered from 60 mg to 5 mg over 3 months with her symptoms returning to baseline and normalization of lab parameters.

DISCUSSION: The diagnosis of idiopathic HES must exclude other causes of eosinophilia such as hematological diseases (especially eosinophilic leukemia) and reactive eosinophilia due to parasitic infections, allergic diseases, drug reactions, autoimmune disease, neoplasm, and vasculitis as these disorders require specific interventions directed at the underlying cause rather than the eosinophilia itself. Therapy is aimed to reduce the number of eosinophils in tissue, and glucocorticoids are first-line. Cytotoxic agents, interferon- α and monoclonal antibodies are considered in refractory cases. A subgroup of patients

with FIP1L1-PDGFR α mutation has a favorable response to imatinib mesylate (1). Our patient's multisystem presentation required consideration of a broad differential as well as ruling out infectious etiologies prior to therapy. Special attention to the organ systems involved (CNS, lungs, heart and kidneys), striking peripheral eosinophilia, bone marrow biopsy findings and ruling out other possible causes led the clinicians to a diagnosis of acquired hypereosinophilic syndrome (HES), which would not be a part of routine differential diagnosis. References: 1. Valent P, Klion AD, Horny H-P, Roufosse F, Gotlib J, Weller PF, et al. Contemporary consensus proposal on criteria and classification of eosinophilic disorders and related syndromes. *J Allergy Clin Immunol.* 2012 Sep;130(3):607–612.e9.

THE WILY WOLF: PERSISTENT FEVERS, TRANSAMINITIS, AND PANCYTOPENIA SECONDARY TO SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN PREVIOUSLY HEALTHY MALE Syed Ali^{2,1}, Katerina Kovalenko²; Weija Wang²; Laura K. Snyderman². ¹Tufts University Medical School, Medford, MA; ²Tufts Medical Center, Boston, MA. (*Tracking ID #1925626*)

LEARNING OBJECTIVE 1: 1. Understand that SLE may present initially with normal or only mildly abnormal serologic findings but may change with disease course, and negative biomarkers should be interpreted in the context of the clinical picture.

LEARNING OBJECTIVE 2: 2. Importance of having a broad differential and a type II clinical reasoning approach for patients with non-specific systemic symptoms.

CASE: A 28-year-old Cape Verdean man with no past medical history presented to an outside hospital with 1.5 months of proximal muscle weakness, myalgias, fevers, palmar rash, fatigue and 15 lb weight loss. He was found to have transaminitis and pancytopenia. An extensive infectious disease, rheumatologic and hematology/oncology workup, which included palmar biopsy and bone marrow biopsy, did not yield a diagnosis and he was discharged after 3 weeks. Two weeks later, he was admitted to our hospital with these same complaints in addition to low back pain. Exam was significant for 3/5 proximal muscle strength (quadriceps, biceps, triceps), left inguinal lymphadenopathy and palmar rash. Laboratory data revealed transaminitis (AST 600 s, ALT 200 s), severe pancytopenia (WBC 0.9, HgB 7.3, HCT 21.1, plt 76), CPK>1200, and elevated serum ACE 111. Imaging revealed a splenic infarct and myositis. Biopsy of paraspinal muscle, left inguinal lymph node and bone marrow was unrevealing. Infectious disease workup, including hepatitis, HIV, HTLV, malaria, CMV, EBV, RPR, tick-borne illnesses, parvovirus, toxoplasmosis, legionella, cryptococcus, enterovirus, coxsackie, and histoplasmosis was negative. All rheumatologic tests were unremarkable except for a slightly elevated ANA 1:160 in the setting of negative ds-DNA and anti-Smith antibody. PPD was negative, and Quantiferon Gold was indeterminate \times 2, however these results were felt to be inconclusive due to the patient's profound pancytopenia. The patient was treated with Cefepime for neutropenic fever but continued to spike temperatures $>39^{\circ}\text{C}$. After 2.5 weeks, our differential diagnosis included military tuberculosis (his son was being treated for latent TB), an unclear autoimmune process, sarcoidosis, and hemophagocytosis. Anti-TB treatment with moxifloxacin, ethambutol, and rifampin was started but didn't show improvement after 4 days. Then the anti-TB medications were stopped and IV Solumedrol was started to treat a possible autoimmune process. Once steroids were started his blood counts improved and he began to feel well enough for discharge to inpatient rehab. At his follow up appointment in Rheumatology a month later, his ANA was 1:320 and his repeat ds-DNA was positive. Despite feeling 85 % of his normal self, his protein/creatinine ratio was uptrending, raising concern for developing lupus nephritis.

DISCUSSION: This case demonstrates the protean manifestations of SLE in a young, otherwise healthy male. SLE is a chronic inflammatory disease of unknown etiology that typically presents with a constellation of constitutional, hematologic and serologic findings and can affect almost any organ. Almost all patients experience fatigue, fever and arthralgias. A significant portion also have hematologic findings, including anemia, leukopenia, thrombocytopenia, and pancytopenia. A formal diagnosis of SLE requires the presence of 4 out of 11 criteria: malar rash, discoid rash, photosensitivity, oral ulcers, arthritis, serositis; renal, neurologic and hematologic disorders; and elevated ANA and one other serologic marker (anti-dsDNA, anti-Sm, APLA). Our patient has 3 criteria: pancytopenia, elevated dsDNA, and elevated ANA. His developing lupus nephritis would make it 4 criteria and a definite diagnosis. Approximately half of patients who present with a positive ANA and fewer than 4 criteria eventually accumulate enough criteria for a diagnosis of lupus. It is interesting to note that although dsDNA only has a 75 % sensitivity for SLE, it is a risk factor for developing lupus nephritis. Other risk factors include being young, male, black, and having positive anti-Smith and lupus anticoagulant. Serologies may be equivocal and can

fluctuate throughout the disease course, so it is important to interpret them in the context of the clinical picture, and to recheck them if clinical suspicion of SLE remains high. SLE can be difficult to diagnose due to its variable presentation. It's important to remember that although 84 % of patients with SLE are female, there are 25,000 males with this disease in the US, so keep it on the differential for patients presenting with systemic, nonspecific symptoms. Next, SLE is resistant to type I reasoning due to its unpredictable pattern. It is therefore important to apply type II clinical reasoning and to systematically develop a differential. Finally, cases like this require the collaboration of multiple teams who need to practice good communication and documentation. The coordination of care falls to the primary team to ensure sound (and safe) clinical decision making based on synthesized data and opinions.

THE WRONG SIDE OF THE TRACKS Uchechukwu Obih; Beth Susi; Thomas Montgomery. Carolinas Medical Center, Charlotte, NC. (*Tracking ID #1926364*)

LEARNING OBJECTIVE 1: Discuss the importance of obtaining thorough social history.

LEARNING OBJECTIVE 2: Identify a noninfectious cause of thrombotic thrombocytopenic purpura (TTP)

CASE: A 21 year old man presented with weakness and lethargy of 1 week's duration. He complained of nausea, vomiting, diffuse abdominal achiness, chills, and headaches. His past medical history was notable for chronic back pain secondary to a horsing accident as a child. Exam showed a heart rate of 100, diffuse abdominal tenderness, and splenomegaly. His sclera, face, chest, back, and arms were jaundiced, with petechiae on his upper back, and a large tattoo on his left forearm and upper back. No focal neurologic deficits were present. Laboratory was notable for white blood cell count of 7.4 g/dL with 20 % bandemia, hemoglobin of 5.5 g/dL, MCV 114, platelets of 13 K/uL. Other pertinent labs included potassium of 2.8 mmol/L, creatinine of 1.59 mg/dL, albumin 2.6 g/dL, total protein 5.1 g/dL, total bilirubin 4.0 mg/dL, alkaline phosphatase of 54 IU/L, ALT 241 IU/L, AST 137 IU/L, and CPK 78 IU/L. Lactate dehydrogenase was elevated at 1,627, haptoglobin was low at 2 and peripheral smear showed 1+ schistocytes. Urine drug screen was negative for Tylenol, salicylates, ethanol, barbituates, marijuana, or opioids. Hepatitis C was positive with viral load of 51,000 copies. HIV was negative. He was admitted to the intensive care unit to begin plasma exchange and steroids for concern of thrombotic thrombocytopenic purpura (TTP). His thrombocytopenia and anemia had slow resolution and plateaued by cycle ten of exchange. As his jaundice and petechiae improved, track marks were noted in the left antecubital fossa. The patient revealed that his brother presented to another hospital with similar symptoms and was also diagnosed with TTP. He admitted to injecting extended-release oxymorphone with his brother 1 week prior to the start of his symptoms. Plasma exchange and steroids were discontinued with improvement in anemia and thrombocytopenia.

DISCUSSION: Obtaining a thorough social history, including exposure to medications and illicit drugs is important in diagnosing thrombotic thrombocytopenic purpura (TTP). TTP is defined by the pentad of microangiopathic hemolytic anemia determined by the presence of schistocytes, elevated LDH and low haptoglobin, thrombocytopenia, fever, neurologic symptoms, and renal dysfunction. Etiology has been associated with ADAMSTS-13 activity deficiency and with Shiga-like toxin from diarrheal illness caused by enterohemorrhagic Escherichia coli O157:H7. A number of medications, such as cisplatin, bleomycin, and mitomycin have been implicated in the development of TTP in some patients. TTP induced by intravenous injection of extended release oxymorphone is a rare cause, of which there have been a few reported cases to the Centers for Disease Control. Treatment for drug induced TTP has not been established. While plasma exchange has become the mainstay of treatment for TTP secondary to ADAMTS13 deficiency or E. coli, evidence of use in drug induced TTP is not robust and is anecdotal. Supportive care is often the treatment of choice.

THERE'S AN UNCOMMON FUNGUS AMONG US Prathyusha Savjani. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1926142*)

LEARNING OBJECTIVE 1: Understand the importance of obtaining tissue diagnosis in patients with cerebral infections while on immunosuppressive agents to accurately identify the disease.

LEARNING OBJECTIVE 2: Recognize how the differential diagnosis for infection changes based on the immunosuppressive agent being used

CASE: A 62 year-old African American man with a history of cadaveric kidney transplant presented with sudden onset of right arm weakness. MRI of the brain was obtained due to concern for stroke. On imaging, it was discovered that he had

multiple peripherally enhancing lesions scattered throughout the cerebral parenchyma. The differential for such findings included metastatic disease, primary malignancy, infectious etiologies, and demyelinating processes. Cerebrospinal fluid analysis was normal as was serum testing for infectious etiologies of cerebral abscesses. He then underwent craniotomy with biopsy with preliminary fungal cultures showing light mold. Pathologic evaluation of the brain sample demonstrated acute granulomatous cerebritis containing pigmented hyphal forms consistent with dematiaceous fungi. Final fungal culture results yielded Fonsecaea pedrosoi. Investigation to identify a primary source of entrance for this organism included thorough investigation of the skin and sinuses. The only skin lesion noted was a chronic non-healing ulcer on his back that was previously biopsied and determined to be radiation dermatitis as a result of fluoroscopic procedures. Dermatology was consulted and did not believe that this skin finding was consistent with a fungal infection. The sinuses were patent with no thickening of any mucosal tissue on both CT and MRI of the head and thus sinus disease was ruled out. Treatment options were discussed including Amphotericin B, Itraconazole, Voriconazole, as well as surgical debridement of the abscesses. The patient chose not to undergo any further invasive procedures, and treatment was initiated with Amphotericin B and Voriconazole and the transitioned to Itraconazole at discharge. He was followed-up in the outpatient setting by the infectious disease team with a repeat MRI of the brain several weeks after treatment. It showed stable lesions that had neither grown nor shrunk in size. The patient's symptoms remained stable with no improvement but also with no deterioration of neurologic deficits.

DISCUSSION: Chromoblastomycosis of the central nervous system by F.pedrosoi is a very rare disease throughout the world and even more rare in the United States. This fungal organism is generally found in rotten wood and soil in humid regions. Most reported incidences of this infection involve skin and subcutaneous infection from direct inoculation, which can occur in both immunocompetent and immunocompromised hosts. Most of the previous cases come from Asia, South America and Africa where the environment is friendlier to this organism. Cases of brain abscesses with this organism have been reported in patients with an altered immune system and most had a primary cutaneous site of inoculation. The mechanism by which this organism reaches the central nervous system is not known. This patient was on Tacrolimus, which by inhibiting T-cell activation, likely predisposed this patient to developing this fungal infection. One should build a differential diagnosis based not only on imaging, previous cases, and patient's exposures, but also on the immunologic effects of the immunosuppressant being used. T cells are the cornerstones of immunologic response to fungal infections, and suppression of T cell function by medications such as Tacrolimus may predispose to fungal infections consisting of very rare organisms.

THESE DEVICES CAN BREAK SKIN!!! Samian Sulaiman; Muhammed Sherid; Salih Samo; Shahriar Dadkhah; Nadia El Hangouche; Muhammad Shahreyar; Addis Asfaw; Ahmet A. Oktay; Ana Inashvili; Husein Husein; Preethi Subramanian. St. Francis Hospital. Evanston, IL. (*Tracking ID #1938782*)

LEARNING OBJECTIVE 1: Despite improvements in the design and implantation techniques of permanent pacemakers, infection and skin erosion of the pacemaker pocket remain a serious problem. Continuous or recurrent pain at the pocket site should raise suspicion of infection. It is crucial to identify early signs of pocket infection before these devices breaks skin. Regular pacemaker check-up helps avoid late complications of pacemakers

CASE: - A 77 y/o Male who presented with redness and discomfort over his pacemaker pocket in the left upper chest. The pacemaker was implanted 2 years ago. The current complaint started 4 weeks ago. Despite outpatient oral antibiotics, his erythema progressively worsened and developed into a superficial ulcer with draining pus. Patient was admitted to our hospital to receive IV antibiotics. - On physical exam, Tenderness and erythema were noticed at pacemaker site with a superficial small ulcer. Patient was afebrile and rest of vital signs were normal except for irregular heart beats. - His past medical history was significant for atrial fibrillation, Diabetes mellitus, hypothyroidism and Hyperlipidemia. His medications included Coumadin, levothyroxine, atorvastatin, Cardizem, metoprolol and metformin - Patient was started on IV vancomycin and Zosyn. Blood and wound cultures were neg. Transthoracic Echocardiography did not show any vegetation. CT chest (see Figure 3) showed Skin and soft tissue thickening superficial to the pacemaker device but no abscess was present. His erythema and drainage resolved and he was discharged home on oral augmentin on sixth day of admission. Ten days after discharge, he presented again with a skin break at pacemaker's pocket. Patient reported episodes of local irritation to which he responded by rubbing his skin. On physical exam, part of pacemaker hardware was exposed (see Fig 1). Cardiothoracic surgeon replaced the pacemaker and extracted intra-cardiac leads. Pacemaker lead tip culture grew Staph Epidermidis susceptible to multiple antibiotics including vancomycin. Patient received extended course of antibiotics for 4 weeks.

DISCUSSION: The overall incidence of pacemaker-related infections is 1.9 per 1000 device-years. Several factors are associated with an increased risk of Permanent pacemaker infections, including diabetes mellitus, malignancy, operator inexperience, advanced age, corticosteroid use, anticoagulation, recent device manipulation, chronic renal failure, and bacteremia from a distant focus of infection. Early post-implantation infections are most commonly caused by *Staphylococcus aureus* and late infections most commonly by *Staphylococcus Epidermidis*. There is a general consensus that once there is deep pacemaker pocket or lead infection, removal of the whole pacemaker system followed by an extended course of appropriate antibiotics results in the best prospect for long term eradication of infection. If pacemaker erodes the overlying skin, it is considered contaminated and current opinion favors replacement of the generator and leads. The mortality of persistent infection when infected leads are not removed can be as high as 66 %.

THIS IS MORE THAN A SIMPLE AKI! Hani Snounou. Saint Francis Hospital, Evanston, IL. (*Tracking ID #1934404*)

LEARNING OBJECTIVE 1: To recognize the reciprocal relationship between the uric acid level and acute kidney injury.

CASE: A 62 year old male presented with melena stool, generalized weakness, low Urine output for 1 week duration. He is a reformed alcoholic with underlying cirrhosis but he admits returning to drink 2 weeks before the admission due to social stress. Otherwise he has a past medical history of Diabetes mellitus, Hypertension, diastolic CHF and COPD. Home medications were metformin, glimepiride, lisinopril, Lasix, advair and albuterol PRN. Physical examination at the time of admission was remarkable for obesity with BMI of 44, jaundice and mild tenderness in the right upper quadrant and epigastric area, the rectal exam with melena stool. His initial labs showed creatinine of 7.2 mg/dL (with a historical creatinine of 0.9 1 year ago), BUN of 98 mg/dL, NA of 130 mmol/L, chloride of 84 mmol/L, hemoglobin of 12.1 g/dL, PLT of 129 K/mL, normal INR/PT, AST of 311 IU/L, ALT of 194 IU/L, total bilirubin of 4.9 mg/dL with direct bilirubin of 3 mg/dL, alkaline phosphatase of 163 IU/L. Hospital Course: The initial AKI workup showed a CK of 424 IU/L, Uric acid of 23.2 mg/dL, FENA of 1.24 %, urine PH of 5 with +30 protein without casts seen; CT abdomen without contrast showed fatty liver, normal kidneys texture without hydronephrosis or ascites. The patient underwent EGD and colonoscopy and no active bleeding was found. He was placed on half saline with 75 Meq of sodium bicarbonate at 100 cm³/h and was given one dose of rasburicase 5 Mg. His creatinine and the Urine output improved during the admission as well as the uric acid level as following: Creatinine trend: 7.2 → 6.6 → 5 → 4.0 Uric acid trend: 23.2 → 22 → 20 → 16 He was discharged and asked to follow up with his PCP when he had a repeat blood workup after 2 weeks showing normalization of the creatinine to 0.9 mg/dL and a uric acid of 7.8 mg/dL.

DISCUSSION: Acute uric acid nephropathy or UAN is a well known syndrome most frequently encountered in the course of rapid cell turnover such as leukemias and lymphomas, and the added acceleration of cell lysis that occurs with chemotherapy and radiation. But this pathology can be seen even with no malignancy history as in our case. The uric acid elevation can be the reason or the consequence of the AKI but a level above 12 is rarely to be due to the AKI by itself. High tubular fluid flow diuresis achieved by hydration is the primary mechanism of both protection and treating acute uric acid nephropathy. Urine alkalinization is controversial since it may sometimes accelerate phosphate precipitation in the kidneys and thereby worsen the renal failure, but this technique still commonly used. Using rasburicase helps to bring the uric acid level faster and can be considered as treatment option and a good outcome can be seen even with a single dose as in our case. Finally hemodialysis therapy may be required both to correct azotemia and to reduce the body burden of uric acid.

THROW ME A BONE: A CASE OF LANGERHANS CELL HISTIOCYTOSIS PRESENTING AS RIB PAIN IN A 35-YEAR-OLD WOMAN Julia P. Brockway¹; Elena Katz²; Sudha Dubey¹. ¹Beth Israel Medical Center, New York, NY; ²Beth Israel Medical Center, New York, NY. (*Tracking ID #1936915*)

LEARNING OBJECTIVE 1: Recognize Langerhans cell histiocytosis as an uncommon etiology of bone pain and lytic bone lesions in adults.

LEARNING OBJECTIVE 2: Learn how to diagnose Langerhans cell histiocytosis and assess for multi-organ involvement.

CASE: A 35-year-old African American woman presented with intermittent right breast pain for 2 months. Three months prior she had presented to an outside clinic with a right breast lump. Ultrasound of the breast at that time showed two breast masses and a suspicious enhancement at the right fifth rib. The breast masses proved to be fibroadenomas on core biopsy. She was then referred for CT scan of the chest,

after which she transferred her care to our institution. She now had right breast pain and a throbbing rib pain inferior to the breast. She also noted an unintentional 7 lb weight loss over 2 months. She denied fevers, night sweats, shortness of breath, or cough. Her right breast was tender to palpation in the lower inner quadrant and had a palpable, non-tender mass at 10 o'clock. There was no cervical, supraclavicular, or axillary lymphadenopathy. Lung exam was unremarkable. CBC showed mild neutropenia with an ANC of 1400/uL, hemoglobin of 12.5 g/dL, and platelets of 180 K/uL. Liver and renal function tests were normal, and calcium level was 8.7 mg/dL. Serum and urine protein electrophoresis showed no abnormal bands. CT scan of the chest revealed lytic lesions in the fifth and sixth ribs with an associated expansile soft tissue mass at the fifth rib. Biopsy of the rib mass was performed and pathology revealed eosinophilic granuloma, with no tumor seen. Immunohistochemistry stained positive for CD1a, S100, and CD207, consistent with a diagnosis of Langerhans cell histiocytosis (LCH). PET CT scan showed additional suspicious foci at the left hip and left maxilla, and interval development of numerous thin-walled cysts in the mid-to upper-lungs suggestive of pulmonary eosinophilic granulomatous disease. Bone marrow biopsy showed normocellular marrow. The patient was diagnosed with multi-system LCH without "risk organ" involvement. She was referred to hematology/oncology to explore treatment options, and her care was ultimately transferred to an outside cancer center to participate in a clinical trial.

DISCUSSION: LCH is an uncommon cause of lytic bone lesions in adults. The estimated incidence is one to two cases per million adults; however, the true incidence is not known, and LCH is thought to be under diagnosed. The differential diagnosis for lytic skeletal lesions, depending on a patient's age, includes primary bone or soft tissue tumor, multiple myeloma, and metastatic disease. Definitive diagnosis can therefore only be made by biopsy of a suspicious lesion. LCH is a disorder of histiocytes that originates from the myeloid dendritic cell, a precursor of the Langerhans cells found in skin and mucosa. Pathophysiology is ambiguous, though evidence suggests a neoplastic process, a reactive process, or a combination of both. Histiocytes infiltrate various organs, including bones, skin, lymph nodes, the liver, the spleen, the lungs, and the central nervous system. While the most common presentation is pain due to lytic bone lesions, patients may also present with dyspnea due to lung involvement, rash, gingival hypertrophy, weight loss, fever, lymphadenopathy, splenomegaly, or polydipsia, polyuria, ataxia, or memory problems due to CNS involvement. About half of all patients diagnosed with LCH present without systemic symptoms and with involvement of only one organ, such as the lungs in primary pulmonary LCH. The rest are considered to have multi-system LCH, involving two or more organ systems with or without involvement of the "risk organs" (bone marrow, spleen, and liver) which portend a worse prognosis. Classification of a patient's disease is critical, as it determines the specific type of treatment needed. All patients should be evaluated after initial diagnosis with a thorough physical exam, CBC, renal and liver function studies, skeletal survey, chest x-ray, and PET CT scan. Patients with multi-organ involvement or cytopenias must undergo bone marrow biopsy. Treatment of LCH depends on patient age and whether it is single or multi-system disease with or without "risk organ" involvement. For adults with single site disease, management ranges from watchful waiting to local methods such as curettage, topical steroids, or radiation therapy. For patients with multisystem disease, data is limited, and patients are encouraged to participate in clinical trials. The mainstay of treatment is chemotherapy. Prospective trials have shown that the majority of these patients respond to initial treatment; however, patients must be closely followed for disease recurrence after completing therapy. Further research is needed in order to better understand LCH, its pathophysiology, and its treatment. It is important for clinicians to be aware of this rare but potentially treatable disease and the various ways that it can present.

THYROID-INDUCED ATRIAL FIBRILLATION Farah Kaikow; Philip J. Putnam. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1925927*)

LEARNING OBJECTIVE 1: Diagnose thyroid disease as a cause of new-onset atrial fibrillation.

LEARNING OBJECTIVE 2: Recognize that thyroid disease workup can be limited by amiodarone administration.

CASE: A 65-year-old man presented with sudden-onset shortness of breath for 1 day. He was at home watching television when the dyspnea started. After a few minutes he began to have blurry vision and lightheadedness. The patient denied any associated chest pain or tightness. Past medical history was significant for hypertension and Type 2 diabetes, both well controlled. Review of systems was positive for dyspnea on exertion over the preceding 2 weeks that was associated with symptoms of a mild upper respiratory tract infection including rhinorrhea and cough. The patient's heart rate was 136 and electrocardiogram revealed atrial fibrillation with rapid ventricular

response. Vital signs were otherwise within normal limits. The patient had mild crackles at both lung bases and an otherwise normal exam. A diagnosis of mild heart failure secondary to new arrhythmia was made and amiodarone was started to control the heart rate and rhythm. Upon further workup, blood tests revealed an undetectable thyroid stimulating hormone level and an elevated free T4. The patient had previously been euthyroid. The diagnosis was then amended to include hyperthyroid as the underlying cause of the atrial fibrillation. While viral thyroiditis was thought to be the most likely source of the hyperthyroid disease, further workup with radioactive iodine uptake scan was not able to be performed because of the initial administration of amiodarone.

DISCUSSION: Atrial fibrillation is the most common arrhythmia diagnosed in the United States and thus a condition in which general internists should be well versed. Approximately 1 % of cases of this arrhythmia can be linked to hyperthyroidism, and about 1.7 % of patients with new hyperthyroid disease have simultaneous atrial fibrillation. Although hyperthyroid is much more common in women than in men, hyperthyroid-induced atrial fibrillation is more than twice as common in men than women. When a patient presents with new-onset atrial fibrillation, the minimum workup that should be performed includes a 12-lead electrocardiogram, chest x-ray, transthoracic echocardiogram, and thyroid function tests. The goal of this workup is to rule out treatable causes of atrial fibrillation, such as hypertension, heart failure, myocardial ischemia, pulmonary disease, and thyrotoxicosis. In hemodynamically stable patients, there is no need to urgently control the abnormal rhythm. First line therapy is rate control with beta-blockers or calcium channel blockers. In cases where hypotension or heart failure is a significant concern, amiodarone is a reasonable alternative. However, if there is any concern for possible thyroid disease as the etiology of the arrhythmia, amiodarone should be avoided as it can both exacerbate thyroid disease and invalidate results of a radioactive iodine uptake scan. In this case, given the patient's stable vital signs, absent history or exam findings of significant heart failure, and recent upper respiratory infection symptoms, it would have been reasonable to postpone amiodarone administration until further lab results were available.

THYROTOXIC HYPOKALEMIC PERIODIC PARALYSIS Saifullah Nasir^{1,2}; Jeffrey T. Bates^{2,1}. ¹Baylor College of Medicine, Houston, TX; ²Houston VAMC, Houston, TX. (*Tracking ID #1939642*)

LEARNING OBJECTIVE 1: Recognize Thyrotoxic Hypokalemic Periodic Paralysis (THPP) as a potential cause of weakness or paralysis.

LEARNING OBJECTIVE 2: Manage the hypokalemia and hyperthyroidism of Thyrotoxic Hypokalemic Periodic Paralysis (THPP).

CASE: A 36-year-old Vietnamese female without prior medical history presented with acute onset of several hours of bilateral lower extremity weakness. Over the previous 3 months, she had noticed a 10–15 lb unintentional weight loss, an intermittent throat pain which resolved with pain medications, and an occasional tremor of her hands. There was no trauma, recent illness, vision problems, or dizziness. Physical examination revealed tachycardia to 110, non-tender thyromegaly with a right thyroid lobe larger than the left, and an enlarged isthmus. There were no palpable thyroid nodules, no lymphadenopathy, and no thyroid bruit. There was no lid lag and no periorbital edema or chemosis. The patient's lower extremity weakness was localized to her proximal thighs, but she was able to stand with some support. Laboratory data showed a potassium of 2.3 mmol/L, TSH of <0.01 U/mL, free thyroxine level of 4.08 ng/dL, and a free T3 of 18.25 pg/mL. An ultrasound of the neck revealed a diffusely enlarged thyroid gland with increased vascularity and no discrete nodules. Her potassium was repleted and her weakness immediately resolved. She was diagnosed with hyperthyroidism and started on both propranolol and methimazole.

DISCUSSION: Thyrotoxic hypokalemic periodic paralysis (THPP) occurs in up to 1.9 % of Asian males with hyperthyroidism. It can also occur less frequently in females as well as patients of other ethnicities. In cases of periodic paralysis weakness resolves completely with correction of hypokalemia. A hyperadrenergic state from hyperthyroidism leads to an increase in insulin secretion, which then leads to an intracellular shift in potassium. Serious complications include respiratory failure from weakness of the diaphragm and arrhythmias from hypokalemia. Clinicians should recognize THPP as a possible cause of paralysis or muscle weakness. Prompt treatment of hypokalemia and hyperthyroidism is necessary for resolution of paralysis and to prevent future attacks. However, clinicians should also be careful not to overcorrect hypokalemia, as the total body potassium in these patients is not low.

THYROTOXIC HYPOKALEMIC PERIODIC PARALYSIS IN A HISPANIC PATIENT: A RARE PRESENTATION OF GRAVES' DISEASE Abhishek Matta; James Fulton; Jahnavi Koppala; Ahmed Abuzaid; Khaled M. Abouelezz; Arun Nagabandi. Creighton University Medical Center, Omaha, NE. (*Tracking ID #1939520*)

LEARNING OBJECTIVE 1: Thyrotoxic hypokalemic periodic paralysis should be considered in the differential diagnosis of patients presenting with acute paraplegia or periodic paralysis and the initial work up should include TSH and potassium level

LEARNING OBJECTIVE 2: Potassium replacement and propranolol will lead to rapid recovery from paralysis

CASE: A 26 y/o Hispanic gentleman presented to the emergency room with sudden onset weakness of lower extremities. He denied having such episodes in the past. He denied any weight loss, heat intolerance, anxiety, palpitations, tremors or increased perspiration. He denied any family history of periodic paralysis. His vitals were stable. Neurological examination revealed a power of 1/5 in the low extremities and 3/5 in the upper extremities. Sensations to fine and crude touch were intact. Deep tendon reflexes were diminished. Labs revealed a serum potassium of 1.8 meq/L and TSH of 0.02 mIU/L. EKG revealed prominent U waves. He was started on IV potassium supplementation and he recovered his muscle strength within 6 h. Further investigations revealed a T4 level of 2.32 ng/dL, T3 8.9 ng/dL, TSH receptor antibody 5.78 IU/L, Thyroid stimulating Ig 156. Radioiodine uptake scan of the thyroid showed increased homogenous uptake suggesting Grave's disease. Patient was started on propranolol and methimazole.

DISCUSSION: Thyrotoxic periodic paralysis (TPP) is more common in Asians compared to Hispanics, Caucasians or African-Americans. The incidence on TPP in thyrotoxic patients in North America was found to be 0.1–0.2 %. TPP occurs predominantly in men. TPP has been reported with Grave's disease, toxic nodular goiter, iodine-induced thyrotoxicosis, excessive thyroxine use, solitary toxic thyroid adenoma, lymphocytic thyroiditis and thyrotropin-secreting pituitary adenomas. The usual age at presentation is 20–40 years. Thyroxine directly stimulates the Na⁺K⁺-ATPase pump directly leading to increased transport of potassium into the cells and subsequent hyperpolarization of the cell membrane leading to paralysis. Hyperthyroidism can also lead increased epinephrine release from the adrenal gland which can stimulate the Beta-2 receptors on skeletal muscles and increase K⁺ uptake into the myocytes. TPP only affects the skeletal muscles. The episodes of paralysis are usually periodic and typically start in the proximal muscles of the lower limbs. The triggering factors include exercise, trauma, high carbohydrate diet, emotional stress or cold exposure. Sensory system and mental status are unaffected. Acute management of TPP involves potassium supplementation. Definitive control of hyperthyroidism completely abolishes the attacks of TPP and includes antithyroid medications, surgical thyroidectomy and radioiodine therapy.

TICK-TALK, TICK-TALK: WHEN A FEVER, HEADACHE AND STIFF NECK ISN'T MENINGITIS Akshay Manohar; Andrei Yankovich; Sergey Gerasim; Daniel Goldsmith. Capital Health Regional Medical Center, Trenton, NJ. (*Tracking ID #1939366*)

LEARNING OBJECTIVE 1: Recognize that babesiosis can present in a myriad of symptoms that mimic other illnesses.

LEARNING OBJECTIVE 2: Suspect babesiosis in patients travelling to or living in endemic regions

CASE: A 49-year-old Hispanic male had 2 weeks of non-radiating occipital headache, fevers and chills in early August. The headache progressed and he developed neck stiffness on moving his head side to side, but not up and down. He denied rash, insect-bite, neurological, respiratory, cardiac or abdominal symptoms. He had a past history of dyslipidemia for which he took a statin. He denied any sick contacts. He worked as a road paver and travelled often from central New Jersey where he lived to Pennsylvania, Maryland, Virginia and Washington, DC for work. He denied recent foreign travel or ever entering wooded areas. His physical exam was positive for fever, and neck-stiffness when moving his head side to side. Initial outpatient testing showed a normal basic metabolic panel, mildly elevated bilirubin (1.5 mg/dL) and alkaline phosphatase (178 U/L). Complete blood count showed normal leukocyte count of 7,000 cells/mm³ with 32 % segmented neutrophils, 19 % bands and thrombocytopenia of 55,000 platelets/mm³. He was referred to the ED and underwent lumbar puncture with normal results. Computerized tomography of the abdomen showed multiple hypoattenuations in an enlarged spleen suggestive of infarctions or metastases. A "Malaria" smear was ordered showing ringed trophozoites with light blue cytoplasm and red chromatic dots, confirming babesiosis. The patient was started on Atovaquone, Azithromycin and empirically treated for Lyme disease with Doxycycline. Subsequent testing confirmed positive results for Lyme Disease.

DISCUSSION: Clinical features of Babesia microti infection vary from asymptomatic to severe viral-like symptoms of fever, myalgia, headache, neck stiffness and photophobia. Evidence of hemolytic anemia and thrombocytopenia is common. Severe manifestations such as splenic infarction and rupture, acute respiratory distress syndrome, congestive heart failure, renal failure and disseminated intravascular coagulation can occur. Patients usually

present in endemic regions ranging from Massachusetts to Central New Jersey during the summer months. Given the wide variety of symptoms, patients may present to out-patient clinics or emergency rooms with a wide spectrum of complaints mimicking other illnesses. Diagnosis is confirmed on Giemsa-stained thin blood smears showing ringed trophozoites (Babesia microti) that strongly resemble Plasmodium falciparum. Requiring a skilled technician, parasites may be missed especially when parasitemia is low. Polymerase chain reaction may be used if smears are negative but the diagnosis is suspected. As endemic regions overlap, co-infection by Babesia, Borrelia and Anaplasma occurs commonly.

TICKLE MY NOSE BUT DON'T BREAK MY HEART Pavan Kapadia^{1,2}; Sean M. Lockwood^{2,1}. ¹University of Kentucky Medical Center, Lexington, KY; ²VAMC, Lexington, KY. (*Tracking ID #1940110*)

LEARNING OBJECTIVE 1: Identify nasal packing and intranasal vasoconstrictors as potential causes of Takotsubo cardiomyopathy

LEARNING OBJECTIVE 2: Explore the mechanism of intranasal vasoconstrictors in Takotsubo cardiomyopathy

CASE: A 74-year-old Caucasian female with a medical history of coronary artery disease, hypertension, COPD and diastolic heart failure presented with acute and profound non-traumatic epistaxis requiring intranasal phenylephrine in addition to nasal packing with PVA Expandacell foam (Rhino Rocket) and transfusion of a unit of packed red blood cells. The patient was otherwise asymptomatic but after nasal packing she developed substernal, pressure-type chest pain with only partial resolution of symptoms after 3 sublingual nitroglycerin tablets. Vital signs: Temp 99 °F, BP 134/88, HR 111, RR 34, O₂ Sat 90 % on 2 L. Physical examination was notable for nasal packing and tachycardia on cardiovascular exam. Routine labs were within normal limits however initial troponin I was 0.16 ng/mL, with maximal elevation to 3.33 ng/mL. Electrocardiogram showed sinus tachycardia with new S-T segment elevation in V2-V4. Left heart catheterization showed non-obstructive coronary artery disease however left ventriculography showed a reduced ejection fraction of 25 % with mid-ventricle band akinesis with preserved apical and basal contraction, all consistent with Takotsubo cardiomyopathy. The patient was started on metoprolol and lisinopril prior to discharge and demonstrated return to baseline systolic function at 4 months on transthoracic echocardiogram.

DISCUSSION: Takotsubo cardiomyopathy (TCM), also known as stress cardiomyopathy, is a reversible condition often presenting with anginal chest pain or dyspnea that was first described in Japan for the octopus-like movement exhibited by the left ventricle during systole in heart failure frequently triggered by stressful events. Based on the Mayo Clinic diagnostic criteria, there are 4 major conditions that must be met: 1) transient hypokinesis, akinesis or dyskinesis of the left ventricular mid segments; 2) absence of obstructive coronary disease; 3) new electrocardiographic abnormalities or cardiac biomarker elevation; 4) absence of other identifiable causes, including pheochromocytoma or myocarditis. Post-surgical and post-traumatic nasal packing with intranasal application of vasoconstrictors such as epinephrine or oxymetazoline have been reported in several cases as inciting events for TCM. We present a case of TCM after intranasal phenylephrine administration. Given that phenylephrine causes vasoconstriction in much the same manner as the others and remains a core component of epistaxis treatment in most emergency departments, this highlights the importance of judicious use of vasoconstrictors as a whole in at risk populations. One mechanism hypothesized for the syndrome is an increased sympathetic stimulation and a sudden surge of catecholamines incited by stressful events causing acute vasospasms or exacerbating pre-existing conditions such as microvascular dysfunction and left ventricular outflow tract obstruction and essentially stunning the myocardium. It is hypothesized that intravenous administration and similarly the intranasal application of vasoconstrictors such as phenylephrine can cause a similar manner of catecholamine surge and can thus trigger a TCM.

TIME IS OF THE ESSENCE: A PATIENT PRESENTING WITH ALTERED MENTAL STATUS AND A RISING CREATINE KINASE Megan E. Rau. Wake Forest University, Winston-Salem, NC. (*Tracking ID #1940107*)

LEARNING OBJECTIVE 1: Recognize the less common early signs and symptoms of acute aortic dissections to promote early detection and intervention.

LEARNING OBJECTIVE 2: Reinforce that CT and TTE are the most commonly used imaging modalities in the acute setting to diagnose an aortic dissection.

CASE: A 47-year-old man was driving to a lunch meeting when he experienced shortness of breath, dull chest pain, left arm pain, the inability to speak, and left sided paralysis. Upon arrival to the outside hospital emergency department (ED) the patient's shortness of breath, chest pain, aphasia, and left sided weakness had

resolved. A CT head image was performed followed by an MRI brain scan; both negative for intracranial abnormalities. Labs included a urine drug screen, CBC, CMP, blood alcohol, troponin, urine analysis, creatine kinase (CK) and ammonia level. Noted abnormalities included hyponatremia and slightly elevated CK. While in the ED he developed intense bilateral leg pain and became extremely agitated. He was given 1 mg Dilaudid, 4 mg Ativan, and finally 10 mg of Haldol. Due to continued altered mental status the patient was transferred to Wake Forest Baptist Medical Center (WFBMC) for further evaluation. At the WFBMC ED, the patient continued to be altered and the only abnormal vital sign was a temperature of 101.2° Fahrenheit. A lumbar puncture was performed and unremarkable. Repeat labs revealed WBC 13.1, Na 127 mmol/L, troponin WNL, lactic acid WNL, CK 8,861 U/L, TSH within normal limits (WNL), and HIV negative. Electrocardiogram was unremarkable and chest x-ray showed prominent interstitium with indistinctness of interstitial markings. He was then admitted for further monitoring. At admission his only complaint was a dull, non-radiating pain in the arch of his left foot. History was relevant for a brother who had a heart attack at age 48. Physical exam was notable for dilated, sluggish pupils, and slow speech. His CK was trended and continued to rise over night from 9,737 U/L to 10,593 U/L to 14,536 U/L by mid morning. A transthoracic echocardiogram (TTE) with bubble study was performed to evaluate for a cardiac shunt. No shunt was found but the image revealed a Type A aortic dissection with an intimal flap visualized in the ascending aorta. The flap originated a few millimeters beyond the sinotubular junction and the distal point was unable to be visualized. He also had a moderate sized loculated anterior pericardial effusion. Cardiothoracic surgery was immediately consulted and he was taken for emergency repair. Unfortunately during transport the patient developed chest pain, bradycardia, and pulse-less electric activity requiring initiation of cardio-pulmonary resuscitation. The patient was intubated and surgery was immediately performed. The dissection was repaired and after recovery from his surgery, the patient was discharged home 18 days after admission.

DISCUSSION: Aortic aneurysms are the 13th leading cause of death in the United States with 15,000 people dying each year after rupture. This is due to most aortic aneurysms going undetected until rupture. Once the aneurysm ruptures the mortality rates are as high as 90 %. It is crucial that providers be cognizant of the deadly potentially and need for early, rapid detection of aortic aneurysms. Chest pain is the most common symptom but acute aortic dissection may mimic the signs and symptoms of other acute diseases including abdominal pain, acute mental status changes, and rhabdomyolysis. An elevated CK in a patient with chest pain, even if transient, qualifies acute aortic dissection to be placed on the differential and further evaluation to take place. The most common imaging modality world wide for the diagnosis of acute aortic dissection is the spiral CT and a less invasive option is the echocardiogram. Once an aneurysm is diagnosed intervention can be performed. It is paramount that providers have knowledge of aortic disease including symptoms beyond the most common of severe chest pain to prompt early diagnosis. By physician awareness of the less common presentation of aortic disease the time to diagnosis can continue to improve and continue to save lives. In the case of the patient presented, he had a history of intermittent chest pain, altered mental status and elevated CK. Imaging was delayed over 18 h and a TTE was initially ordered to evaluate for a possible shunt, not an acute dissection. This patient was lucky imaging was ordered and when his aneurysm ruptured an operating room was only a few feet away.

TO THE RETROPERITONEUM AND BACK: AN INTERNIST'S TALE

Patrick Snyder; Karin Warltier. NYU, New York, NY. (Tracking ID #1927562)

LEARNING OBJECTIVE 1: Recognize the clinical presentation and etiologies of retroperitoneal fibrosis

LEARNING OBJECTIVE 2: Treat retroperitoneal fibrosis

CASE: The patient is a 64 year old Greek man with a past medical history of migraine headaches who presented with abdominal pain. He had been in good health until 2 months prior to admission when he began experiencing sharp epigastric pain that radiated to his lower abdomen, groin and flanks. The pain was associated with fatigue, a 20 lb weight loss, daily sweats and subjective fevers. Examination revealed a frail appearing man with normal vital signs and epigastric tenderness. Laboratory studies included an ESR of 94 mm/h and CRP of 64 mg/L. A contrast enhancing CT scan of the abdomen and pelvis showed an aneurysmal aorta measuring 2.8×2.9 cm with atherosclerotic calcification and irregularity of the wall associated with enhancing near-circumferential periaortic soft tissue thickening beginning just below the renal arteries and extending to the aortoiliac bifurcation. The enhancing area measured up to 15 mm in thickness and encased the aorta with sparing of the posterior side. There was no ureteral involvement. Medication reconciliation was negative for retroperitoneal fibrosis (RPF) associated medications. Markers for

syphilis, hepatitis B, hepatitis C, ANA and ANCA were all negative. PSA was 5.7. Serum IgG4 was mildly elevated, and Quantiferon Gold screen was positive. Systemic steroid therapy was initiated, which improved his abdominal pain significantly. CT guided biopsy was performed and revealed dense collagenous fibrosis with heterogeneous lymphoplasmacytic infiltration without increase in IgG4 expressing plasma cells. Flow cytometry was without immunophenotypic evidence of lymphoma. The diagnosis of idiopathic RPF was confirmed.

DISCUSSION: Retroperitoneal fibrosis, originally known as Ormond's disease, is characterized by the presence of mixed fibrous and inflammatory tissue surrounding the aorta. It is a rare disorder most commonly affecting middle-aged to elderly men [1]. Back and flank pain are the most common presenting symptoms, occurring in over 90 % of patients [1]. B symptoms, including fatigue, anorexia and weight loss can be seen in 50–60 % of cases [2]. Other retroperitoneal organs, including renal arteries, the inferior vena cava, iliac veins and ureters, are also prone to entanglement. Compromise of the renal arteries can cause hypertension. Blockage of the inferior vena cava or iliac veins may lead to peripheral edema. Obliteration of the ureters can be associated with urinary frequency, urgency, oliguria and elevated serum creatinine. Indeed, one study indicated 33 % of cases of RPF present with new-onset hypertension, 23 % with peripheral edema and 67 % with obstructive uropathy [2]. Diagnosis can be made on the basis of abdominal imaging, either sonography or CT. Though presumptive diagnosis can be made solely on the pathognomonic finding of a homogenous periaortic plaque encasing the abdominal aorta on imaging, biopsy is often pursued for confirmation. A histologic pattern of fibroblast proliferation, sclerosis and infiltration of mononuclear cells is characteristic [3]. RPF can occur as a primary idiopathic or secondary condition. A secondary cause of RPF can be identified in nearly 30 % of patients [4]. Common culprits include medications (ergot alkaloids, dopamine agonists and beta blockers), malignancy (lymphoma, carcinoid tumor, breast, prostate and bladder carcinoma), infection (tuberculosis, histoplasmosis and actinomycosis) and history of prior abdominal or pelvic radiation or surgery (lymphadenectomy, colectomy or aneurysmectomy). Multiple theories have been proposed regarding the pathogenesis of primary RPF, but two predominate. The first suggests that it is a localized inflammatory response to oxidized low-density lipoproteins (LDL) from atherosclerotic plaques in the abdominal aorta that have breached its medial layer [3]. The other theory argues RPF is a sequela of a broader systemic autoimmune process. In more recent years, investigation has been done linking idiopathic RPF to the spectrum of IgG4 related disease. In general, therapy is aimed at limiting progression and promoting regression of fibrosis and preventing recurrence of disease. If the RPF is secondary to another cause, treatment is directed at the root problem. While no gold standard based on randomized control trials exists for treatment of primary RPF, steroids are generally first line therapy. Prednisone is routinely dosed at 1 mg/kg daily for the first month then tapered by various protocols for a net length of therapy between 6 months and 2 years [5]. Mycophenylate mofetil, methotrexate and tamoxifen are alternatives if steroids are contraindicated. If obstructive uropathy is present, ureteral stenting, percutaneous nephrostomy or surgery may complement medical management. Progression or regression of disease can be monitored by pain assessment, repeat imaging and trending of ESR and CRP.

TO TREAT OR NOT TO TREAT: AN ASYMPTOMATIC LADY WINDER-MERE SYNDROME

Kevin A. Johnson; Maryam Sattari. University of Florida, Gainesville, FL. (Tracking ID #1935022)

LEARNING OBJECTIVE 1: Recognize clinical and radiographic characteristics of Lady Windermere Syndrome

LEARNING OBJECTIVE 2: Be familiar with important considerations in diagnosis and treatment of Lady Windermere Syndrome

CASE: A 69-year-old female with history of hypertension and diabetes presented with 4 weeks of night sweats, cough productive of clear sputum, and weight loss. She had recently retired from working in an assisted living facility and denied smoking, fever, chills, history of connective tissue or lung disease, sick contacts, or recent travel. Physical examination revealed a thin woman in no apparent distress. Laboratory testing did not reveal significant abnormalities. Computed tomography of chest, abdomen, and pelvis demonstrated small foci of consolidation with air bronchograms in the right middle lobe and lingula, radiological findings consistent with Lady Windermere Syndrome. Bronchoscopy did not reveal any endobronchial lesions. Culture of bronchoalveolar lavage fluid yielded Haemophilus influenzae (H. flu), but was negative for acid-fast bacilli and fungus. She was treated with 2 weeks of Amoxicillin and reported complete resolution of symptoms within 5 days of initiating antibiotics.

DISCUSSION: The term "Lady Windermere syndrome" describes Mycobacterium avium Complex (MAC) infection in right middle lobe or lingula in elderly, often thin, immunocompetent women without significant smoking history or underlying

pulmonary disease. The syndrome is named after a Victorian character in Oscar Wilde's play Lady Windermere's Fan. Voluntary suppression of cough and expectoration in these fastidious women is hypothesized to cause reduced clearance of secretions, thus resulting in a chronic nidus for inflammation and predisposing to infection. Typical radiological findings include cylindrical bronchiectasis and reticulonodular infiltrates involving the right middle lobe or lingula. The disease may have an insidious onset and symptoms, including fever, weight loss, malaise, cough and hemoptysis, may be present for months or years before the diagnosis is made. Early cases may be asymptomatic and only discovered incidentally. Diagnosis can be made by polymerase chain reaction, but identification of the organism from the sputum is difficult. H. Flu typically, on the other hand, usually causes community acquired pneumonia with more acute onset of symptoms, including fever and productive cough. This diagnosis was unexpected in our patient who presented with symptoms and radiographic findings suggestive of an indolent infection. Given the rapid resolution of her symptoms on amoxicillin, we suspect that H. flu was the organism responsible for her presenting symptoms. However, we cannot rule out an underlying asymptomatic MAC infection, responsible for her radiographic abnormalities. MAC must be considered in elderly women with unexplained respiratory symptoms and a tree-in-bud appearance on CT. Our case also demonstrates the importance of bronchoscopy and obtaining cultures when dealing with possibly MAC infections. In fact, making a diagnosis of MAC disease does not mandate therapy, which is a decision based on weighing the risks and benefits of anti-mycobacterial drugs with potentially severe toxicities in these often frail patients. Given the emerging resistance of MAC, treatment should only be initiated once cultures are available and sensitivities can be ascertained.

TOCILIZUMAB-ASSOCIATED "MIGRAINE" Maria Shtessel; Muhammad S. Shahid; Chaya Abelow. Montefiore Medical Center, Bronx, NY. (*Tracking ID #1937861*)

LEARNING OBJECTIVE 1: Diagnosis and management of cryptococcal meningitis in a non-HIV immunocompromised host.

LEARNING OBJECTIVE 2: Recognize the risks associated with interleukin-6 receptor inhibitors.

CASE: A 40 year-old female with a history of migraines and rheumatoid arthritis (RA) presented with 2 weeks of worsening frontal headache associated with nausea and vomiting. She reported that this headache was worse than her usual migraine headaches. Her history was significant for the use of tocilizumab and prednisone for treatment of RA. She was afebrile and her neurological exam was within normal limits. A CT of the head (CTH) was unremarkable. The patient was initially started on treatment for a presumed migraine. On day two of hospitalization she developed symptoms of photophobia, phonophobia and blurred vision. A lumbar puncture was performed, which revealed an opening pressure of 16 cmH2O [normal range 9–18], colorless CSF, WBC 93 [0–5 WBC/mm³], neutrophils 58 %, lymphocytes 42 %, glucose 21 mg/dL [50–75], total protein 195 mg/dL [10–40] and cryptococcal titer of 1:65000. Blood and CSF cultures grew C. neofmans. The patient was started on amphotericin B with flucytosine as induction therapy for cryptococcal meningitis. Two weeks into her admission, the patient had an episode of loss of consciousness while being transferred to a commode. A repeat CTH revealed enlargement of the lateral and third ventricles, consistent with a communicating hydrocephalus, as well as new left lentiform nucleus hypodensities suggestive of cryptococcomas. A lumbar drain was placed for treatment of communicating hydrocephalus. Repeat CSF analysis demonstrated non-sterile CSF with a cryptococcal titer of 1:1000. After completion of induction therapy, the patient was started on fluconazole 800 mg daily for consolidation therapy for a total of 8 weeks. She was discharged on fluconazole 200 mg daily for maintenance therapy for 6–12 months.

DISCUSSION: Headache is a common complaint encountered by the internist. Unrelenting headache, nausea, vomiting, photophobia/phonophobia are common symptoms of meningitis. The differential diagnosis of meningitis in an immunocompromised host includes the same bacterial and viral pathogens as would be suspected in an immunocompetent patient, however, physicians must also be aware of rarer pathogens. These include mycobacterium tuberculosis, fungal organisms such as cryptococcus, sporothrix, histoplasma, and parasitic infections such as toxoplasma, cysticercosis, and schistosoma, among others. Cryptococcal meningitis tends to have a more indolent course with headache being a common initial symptom, as in this patient. The increasing use of IL-6 inhibitors in combination with traditional disease-modifying antirheumatic drugs (DMARDs) for recalcitrant RA requires internists to have a high index of suspicion for unusual pathogens. Tocilizumab is a humanized monoclonal antibody against the interleukin 6 receptor utilized mainly in the treatment of rheumatoid arthritis and juvenile idiopathic arthritis. While reactivation tuberculosis is a well known complication with the use of DMARDs, cryptococcosis and cryptococcal meningitis are less common side effects of such immunosuppressive therapy. Approximately 20 % of the total cases of cryptococcal meningitis occur in individuals who do not have HIV. In hospital mortality ranges from 10 to 12 % for all

patients with cryptococcal meningitis. Laboratory diagnosis can classically be made with India ink staining of CSF, but the yield of this test is lower in non-HIV patients. CSF cultures tend to be positive in 90 % of non-HIV patients. CSF cryptococcal antigen is very sensitive and specific for Cryptococcus, but serial measurements of cryptococcal antigen cannot be used to monitor therapy adequately. Response to treatment needs to be assessed via repeat lumbar puncture 2 weeks after induction therapy. Standard treatment includes high dose amphotericin B and flucytosine for the induction phase followed by fluconazole for the consolidation phase of treatment. Management of intracranial pressure is also critical for a better prognosis in cryptococcal meningitis. Patients with severe symptoms and opening pressure greater than 25 mmHg should have their pressure reduced by 50 % or below 20 mmHg. Repeat lumbar punctures, a temporary lumbar drain, or a ventriculoperitoneal shunt may be necessary.

TOO BLUE NOT TO BE TRUE: A NIGHT FLOAT'S DIAGNOSTIC DILEMMA Minal A. Shah; Anita Sahu; Jeffrey T. Bates. Baylor College Of Medicine, Houston, TX. (*Tracking ID #1939668*)

LEARNING OBJECTIVE 1: Understand saturation gap and how it aids in the diagnosis of methemoglobinemia.

LEARNING OBJECTIVE 2: Identify lidocaine as a medication that commonly causes methemoglobinemia in the inpatient medicine setting

CASE: A 61-year-old female with no past medical history was admitted for surgical resection of a benign pelvic mass. Her post-operative course was complicated by a small bowel obstruction requiring placement of a nasogastric tube for decompression. She complained of a sore throat, so topical benzocaine was administered prior to insertion. Six hours later, her oxygen saturation was measured at 77 %. She reported no shortness of breath or discomfort. The pulse oximeter was repositioned several times with no change in the oxygen saturation. Physical examination was remarkable for tachycardia, cool extremities, and mild cyanosis of the lips, hands, and feet. Lung fields were clear, and she remained alert and oriented. Her saturation did not improve with 100 % oxygen. An arterial blood gas was drawn and was noted to be dark brown in color. The results were pH 7.45, pCO₂ of 37, paO₂ of 355, and a calculated oxygen saturation of 100 %. Given the cyanosis, abnormal coloration of arterial blood, and saturation gap, methemoglobinemia was suspected. The methemoglobin level returned at 57.7 %. Intravenous methylene blue (1 mg/kg) was slowly infused, and the cyanosis resolved within minutes. Her oxygen saturation improved to 93 %, and the methemoglobin level 1 h after administration was less than 5 %. Chart review revealed the only oxidizing agent she had received was the topical benzocaine spray.

DISCUSSION: Patients with methemoglobinemia may have tissue hypoxia with no symptoms. Additionally, subtle signs of tissue hypoxia such as mild cyanosis can be missed if the physician focuses solely on the chest examination. In most clinical scenarios a normal blood gas is reassuring; however, it is important to remember that a blood gas does not evaluate for all causes of tissue hypoxia. The oxygen saturation reported with an arterial blood gas is calculated assuming a normal hemoglobin. A greater than 5 % difference in the oxygen saturation measured by pulse oximetry and the calculated oxygen saturation indicates a saturation gap. This finding should prompt evaluation for abnormal hemoglobin variants. Furthermore, although methemoglobinemia is regarded as a diagnosis typically encountered in the emergency department, studies indicate it is most often diagnosed by internal medicine physicians. General internists should be able to recognize the medications that induce methemoglobinemia and minimize their use, given the rare but life-threatening complication of methemoglobinemia.

TOO MUCH OF "A" GOOD THING Mitra Barahimi¹; Lauren Beste^{1,2}. ¹University of Washington, Seattle, WA; ²VA Puget Sound Healthcare System, Seattle, WA. (*Tracking ID #1930680*)

LEARNING OBJECTIVE 1: Recognize key clinical and diagnostic features of non-cirrhotic portal hypertension

LEARNING OBJECTIVE 2: Summarize the differential diagnosis and workup of non-cirrhotic portal hypertension

CASE: A 54-year-old man with a history of obsessive compulsive personality disorder presented to the hospital with abdominal pain and peripheral edema. He had no known medical history, other than obsessive compulsive personality disorder, and had avoided medical care for over 20 years. He denied foreign travel or family history of liver disease. He reported consuming probiotics and vitamin A supplements. Physical exam demonstrated cachexia, large ascites, and lower extremity edema. Labs were notable for mild transaminitis, normal liver synthetic function, no proteinuria or other signs of renal disease, and negative HIV. Liver ultrasound showed no evidence of cirrhosis, masses, or hepatic vascular occlusion. The patient was discharged on diuretics with outpatient Hepatology followup. Complete workup for causes of liver disease was negative and a TTE was unremarkable. Transjugular liver biopsy was

significant for elevated portal venous wedge pressures, confirming portal hypertension. Hepatic histopathology showed no diagnostic alterations. He was diagnosed with non-cirrhotic portal hypertension, a rare condition associated with only a handful of etiologies including schistosomiasis, HIV, and hypervitaminosis A. Additional histopathologic evaluation revealed rare hypertrophic hepatic stellate cells, suggesting vitamin A-induced hepatotoxicity. After further questioning, the patient reported consuming up to 1,000,000 IU of vitamin A per day, well above the RDA of 900 IU/day. He endorsed extrahepatic signs of vitamin A toxicity including nail fracturing, anorexia, xerosis of his lower extremities, and hair thinning in his pubic region. He was subsequently referred to Nutrition and Mental Health for further counseling regarding his dietary habits.

DISCUSSION: Vitamin A hepatotoxicity has been reported at doses exceeding 50,000 IU/day. This case illustrates that hypervitaminosis A should be suspected in HIV-negative individuals with non-cirrhotic portal hypertension. The mechanism of vitamin A-induced portal hypertension is poorly understood but is believed to result from hypertrophy of hepatic stellate cells as they absorb the vitamin. With regard to prognosis, several case reports describe spontaneous resolution of vitamin A-induced portal hypertension, as well as several examples of progression to death or liver transplantation. At present, there is no treatment to accelerate vitamin A excretion. The patient's prognosis remains guarded, though absence of liver fibrosis on biopsy suggests the potential for recovery.

TOO MUCH OF A GOOD THING: THE OVERDIAGNOSIS AND TREATMENT OF A GERMAN TOURIST Jonathan L. Robbins; Gregory M. Bump; Harish Jasti. University of Pittsburgh Medical Center, Pittsburgh, PA. (*Tracking ID #1925980*)

LEARNING OBJECTIVE 1: Identify the risks of diagnostic testing in patients with a low pretest probability of serious disease.

LEARNING OBJECTIVE 2: Describe the danger of healthcare overuse to individual patients and to the healthcare system.

CASE: An 18 year-old German man on vacation in the United States presented to the emergency department with a one-month history of coughing spells that occurred at night while lying supine, lasted for a minute, and resolved when he sat upright. He denied fevers, chills, weight loss, sputum production, hemoptysis, dyspnea, or chest pain. His past medical history was significant for pneumonia in early childhood that required inpatient hospitalization. He was a high school student with no TB risk factors, alcohol or drug use. Physical examination revealed a well-appearing, physically fit man with normal vital signs. The physical exam was entirely normal. Routine laboratory testing was normal. An HIV test was negative. A chest x-ray (CXR) was read as a large loculated right hydropneumothorax worrisome for empyema. A CT scan of the chest demonstrated a large intraparenchymal fluid and gas collection. A CT-guided pigtail catheter was placed. Fluid from the lesion contained many WBCs, but there were no bacteria on gram stain. Acid fast bacilli and bacterial culture were negative. Rare *Aspergillus fumigatus* were subsequently cultured and the patient was started on voriconazole. Upon further review, given the patient's clinical stability and absence of symptoms throughout the hospitalization, antifungal therapy was discontinued. The pigtail catheter was removed. The patient was discharged with the diagnosis of non-infectious pneumatocele resulting from disruption of the lung architecture from childhood pneumonia. The *Aspergillus* was thought to be a secondary colonizer of the pneumatocele. The patient returned to Germany without incident.

DISCUSSION: The decision to perform a CXR in this patient, who presented with a cough and normal laboratory findings and exam, resulted in an extensive inpatient work-up, including six chest X-rays, two chest CTs, and placement of a pigtail catheter. Diagnostic testing in patients with a low pre-test probability of serious disease has been shown in a recent meta-analysis to have no effect on symptom status, nor on reducing patients' illness worry or anxiety if the diagnostic tests are negative. Furthermore, when the prevalence of a serious condition is between 0.5 and 3.0 %, a diagnostic test with both 90 % sensitivity and 90 % specificity would produce 4 to 19 false-positive results for every true-positive, which leads to invasive and expensive further testing. With respect to the case, one study found that 19 % of all patients with acute cough who underwent a CXR had an incidental finding, only 3 % of which were clinically relevant. Healthcare overuse is defined as a health care service that is provided under circumstances in which its potential for harm exceeds the possible benefit. The Institute of Medicine has found that healthcare overuse results in least 210 billion dollars of unnecessary expenditure per annum. Almost half (42 %) of US primary care physicians believe their own patients receive too much medical care. Incidental findings discovered on imaging are common and frequently result in healthcare overuse. It is essential that providers act judiciously in the choice to use diagnostic tests in patients who are unlikely to have serious disease, as in this case of an 18 year-old man with cough.

TOXIC LEUKOENCEPHALOPATHY FROM HEROIN OVERDOSE - ATYPICAL PRESENTATION AND RECOVERY WITH RESIDUAL AUTONOMIC DYSFUNCTION AND SPASTICITY Taraka Vijay Gadiraaju¹; Dilpreet K. Singh¹; Santhi Gokaraju²; Mary Jo Farmer³. ¹Baystate Medical Center/Tufts University School of Medicine, Springfield, MA; ²Baystate Medical Center/Tufts University School of Medicine, Springfield, MA; ³Baystate Medical Center/Tufts University School of Medicine, Springfield, MA. (*Tracking ID #1939347*)

LEARNING OBJECTIVE 1: Identify the atypical presentation and recovery of Toxic leukoencephalopathy from heroin overdose (Chasing the Dragon), with residual autonomic dysfunction and spasticity.

LEARNING OBJECTIVE 2: Recognize that initial intensive care management followed by supportive care with multidisciplinary approach from occupational therapy, speech therapy, physical therapy and later appropriate rehabilitation can bring dramatic results in few weeks despite high mortality in these patients.

CASE: A 24 year-old-male patient with history of anxiety, depression, OCD, IVDU and drug abuse was brought to the hospital after he was found unresponsive and covered with vomit around his mouth. Patient was seen by his mother 10 h prior to this event and was in his usual state of health. On presentation, he was unresponsive with a GCS of 4, hypotensive with agonal respirations and no response to naloxone. He was intubated, fluid resuscitated and was started on Norepinephrine drip prior to being transferred to ICU. Vancomycin and piperacillin-tazobactam were also started for possible aspiration pneumonia and sepsis. His home medications were fluoxetine and alprazolam. Four weeks prior to this episode, had was admitted to an outside hospital for drug overdose where his girlfriend died on scene but the patient was fortunate enough to be discharged 3 days later to drug rehab program. Exam was benign except for neurologic exam significant for spasticity and GCS of 4. Laboratory work significant for leukocytosis, renal failure, hyperkalemia, rhabdomyolysis, elevated LFTs, lactic acidosis with an osmolar gap of 10. Utox positive for heroin, cocaine, benzodiazepines, and cannabinoids. EEG showed diffuse alpha and excessive beta activity; revealed no active seizure activity, but was consistent with postictal activity/global hypoxia/possible cerebral dysfunction. EKG revealed sinus tachycardia with peaked T waves. CT brain was negative for acute pathology. Chest x-ray was negative for pneumonia. The patient was weaned off the pressor support, remained afebrile with resolution of leukocytosis and the antibiotics were discontinued after 2 days. Patient had many episodes of whole body tremors, posturing, diaphoresis, sinus tachycardia, tachypnea lasting a few minutes but his mental status has not much changed in the first 48 h. These episodes responded to fentanyl and later needed Propofol drip. Twenty-four hour video EEG was negative for seizure activity during the episodes and were thought to be from opioid toxicity/withdrawal. MRI later on showed findings suggestive of diffuse leukoencephalopathy and he was diagnosed with acute toxic leukoencephalopathy secondary to heroin inhalation. He was supportively managed with a hope that it improves over weeks to months.

DISCUSSION: Leukoencephalopathy due to heroine abuse was recognized for over 30 years but the etiology and pathophysiologic factors are still poorly understood. It may result from the inhalation, intravenous injection, or ingestion of substance abuse drugs. The mortality ranges from 23 to 48 %, however, such occurrences are rare, sporadic, and not well studied. Leukoencephalopathy caused by inhalation of heroin, also known as "chasing the dragon" syndrome is one of the most studied of these rare occurrences and the clinical syndrome was described to progress in 3 stages over a course of weeks on most occasions. However, our patient had a dramatic presentation with sepsis like picture on presentation associated symptoms of all stages. He was extubated 2 weeks later and was able to follow commands but continued to have residual autonomic dysfunction which is also unique to our patient and to our knowledge not described in earlier cases. He also continued to have symptoms like fever, rigidity/spasticity, with increased CPK on presentation similar to neuroleptic syndrome but all his symptoms resolved except for spasticity being treated with baclofen. Our patient is still in the hospital 6 weeks later awaiting for placement and we were able to observe his graded improvement over time with supportive care from occupational therapy, speech therapy, physical therapy and now planning on discharge to rehabilitation. Coenzyme Q and vitamin supplements, typically vitamin C and vitamin E, and other antioxidant therapies have been suggested to treat heroin-induced leukoencephalopathy patients. However, there is no strong evidence to support these choices and our patient improved with supportive care in addition to baclofen for the spasticity and amantadine for cognitive impairment. The wide array of causes and unclear understanding for the pathophysiology, with no known cure or treatment makes this an interesting disease and our case stands out with unique presentation of toxic leukoencephalopathy with the typical stages of improvement and residual deficits.

TRANSFUSION MIMICKING ARDS Ravi Thimmisetty; Manogna Nookathota; Ariel Modrykamien. Creighton University Medical Center, Omaha, NE. (*Tracking ID #1926462*)

LEARNING OBJECTIVE 1: • To know the types of transfusion reactions. • TRALI is a rare, clear and present danger to the lungs

CASE: A 59 year old woman came to clinic for elective bronchoscopy for a 2 cm right upper lobe mass. Work up showed hemoglobin 3.4 g and she was admitted. ROS was negative except for some mild exertional dyspnea. PMH included moderate COPD, hypertension, hyperthyroidism, SVT s/p ablation and vitamin D deficiency. Home medications were Spiriva, Ventolin HFA, Norvase, Synthroid, Lunesta, Cingular, Zyrtec, Mimvey. She smoked a pack per day, denied alcohol and worked in a public school. Vitals were normal. Physical exam was unremarkable except for Hepatosplenomegaly. Imaging showed normal chest x-ray. CT scan showed central, lobular, paraseptal emphysematous changes; 2 cm speculated soft tissue density in right upper lobe. Rest of labs were unremarkable except anemia (Hb 3.4) and thrombocytopenia (21). She received 1 unit of PRBC, 2 units of platelets. During second unit of PRBC she developed fever, dyspnea, tachypnea, tachycardia and hypertension. We immediately stopped blood products and intubated her. Stat CXR showed bilateral airspace and interstitial opacities - given rapid appearance of findings; may represent changes related to fluid overload/pulmonary edema. Echo was normal. Repeat CBC showed Hb 5.5, platelets 111. One more unit of PRBC was given without any complications. Patient improved with positive pressure ventilation and was finally extubated on 2nd day. She was eventually discharged on room air.

DISCUSSION: TRALI (Transfusion Related Acute Lung Injury) occurs at a rate of approximately 0.04 to 0.1 % of transfused patients or in approximately 1 in 5000 transfused blood components. Most of the cases are under reported. Within the last 5 years TRALI reactions have been recognized as the leading cause of transfusion-related fatalities in the United States, surpassing hemolytic and septic transfusion reactions. Mortality rates associated with TRALI/possible TRALI have been reported to be as high as 41 to 67 %. TRALI is a clinical diagnosis. Acute onset of hypoxemia during or within 6 h of transfusion, bilateral infiltrates on CXR, no previous Acute Lung Injury, no evidence of circulatory overload points towards a diagnosis of TRALI. Though TRALI has been associated with virtually all blood products, high-plasma-volume components such as plasma, apheresis platelet concentrates, and whole blood have been consistently shown to carry the greatest risk per component or per transfusion episode. To reduce serious transfusion reactions, inappropriate transfusions must be minimized and the decision to transfuse blood products should be taken with care. It is one life-threatening condition which when diagnosed at bedside promptly, can have the potential to save the patient's life. With prompt recognition and supportive measures, we can reduce mortality and also prevent further episodes of TRALI from that donor blood.

TRICKED BY PERSISTENT ST ELEVATIONS Naomi Karlen; George Bensabat; Philip J. Putnam. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1925938*)

LEARNING OBJECTIVE 1: Identify potential causes of ST segment elevation on ECG. **LEARNING OBJECTIVE 2:** Identify non-invasive or minimally invasive diagnostic tests that can be utilized in the diagnosis in hypertrophic cardiomyopathy.

CASE: A 55 year-old woman presented with altered mental status. The patient's family stated that she had become intoxicated and was involved in a verbal altercation with her daughter before complaining of chest pain and becoming obtunded. They reported a past medical history of hypertension, coronary artery disease, and previous AICD implantation. Vital signs revealed blood pressure 74–139/42–87 mmHg and heart rate 52–76 beats/min. Physical examination was notable only for inability to follow commands. Initial lab work revealed troponin I 0.02 ng/ml, NT-proBNP 1923 pg/ml, and blood alcohol level 91 mg/dl. ECG revealed ST elevation in the anterior leads with reciprocal inferolateral ST segment depression. Emergency cardiac catheterization demonstrated patent coronary arteries. Subsequent left ventriculography showed a premature ventricular contraction, after which a paradoxical decrease in pulse pressure was observed. This is consistent with the Brockenbrough-Braunwald-Morrow sign, diagnostic of hypertrophic cardiomyopathy (HCM). Following cardiac catheterization, additional medical records were obtained which demonstrated persistent ST segment elevation on previous ECGs.

DISCUSSION: While the differential diagnosis of an ECG demonstrating ST segment elevation is broad, clinicians must quickly initially identify or rule out acute myocardial infarction. Other diagnoses include HCM, acute pericarditis, bundle branch blocks, and left ventricular hypertrophy. Persistent ST elevations have been observed in patients with HCM. Occurring in one out of 500 people, HCM is a relatively prevalent disease that remains under-diagnosed and continues to be the most common cause of cardiac-related sudden death in people under the age of 30. The presenting symptoms can mimic myocardial infarction with chest pain, palpitations and syncope. Early identification of HCM patients is imperative so that appropriate treatment can be implemented. The mechanism of persistent ST elevation in these patients is unclear, but subepicardial fibrosis may play a role. Prior to invasive testing, a thorough family history for sudden cardiac death is the easiest initial screen for HCM. Diagnosis can be made non-invasively with echocardiogram or cardiac MRI. Imaging demonstrates increased thickness of the left ventricular wall and obstruction of the left

ventricular outflow. Finally, cardiac catheterization can additionally show the Brockenbrough-Braunwald-Morrow sign, as in our patient. When confronted with ST-elevation on EKG, physicians must quickly diagnose and treat the underlying disorder to prevent life-threatening events. Although most physicians would appropriately focus on myocardial infarction as the most likely cause, it is prudent to maintain a reasonable differential diagnosis and pursue alternative studies when an acute coronary syndrome is ruled out.

TROUBLES WITH TRABECULATIONS Brian Cruz; Charles E. Murphy. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1926965*)

LEARNING OBJECTIVE 1: Identify the features of isolated left ventricular noncompaction (LVNC)

LEARNING OBJECTIVE 2: Review the management of LVNC cardiomyopathy

CASE: A 28-year-old woman presents with palpitations. Her palpitations are long-standing for the past 15 years, occurring at least three times per week and lasting for a few minutes. They are associated with chest pressure, diaphoresis, dyspnea, and often lead to presyncope. She denies dyspnea on exertion or orthopnea. She was diagnosed in the past with supraventricular tachycardia and underwent an unsuccessful catheter ablation. She takes propranolol for palpitations and naproxen as needed for migraines. She denies use of tobacco, alcohol, and illicit drugs. There is no family history of palpitations or heart problems and her four children have no medical conditions. Vital signs, physical exam, and laboratory studies are all within normal limits. Electrocardiogram reveals normal sinus rhythm with ST depression and T wave inversions with biphasic T waves in an inferolateral distribution. Transthoracic echocardiogram with echocontrast reveals a normal left ventricular ejection fraction and left ventricular noncompaction, which is confirmed by a computed tomography scan of the heart.

DISCUSSION: Congenital cardiac abnormalities are commonly detected during childhood, but the internist may be the first to diagnose rare abnormalities that are asymptomatic until adulthood. Isolated left ventricular noncompaction is a primary genetic cardiomyopathy that results from the failure of resorption and remodeling of endomyocardial trabeculations during fetal cardiac development (1). Patients frequently remain asymptomatic until adulthood, and present with nonspecific symptoms that include dyspnea, palpitations, chest pain, and atrial fibrillation (2,3). Some patients present with heart failure or embolic events (4). The electrocardiogram is usually abnormal, but there are no characteristic changes; common abnormalities include bundle branch block, fascicular block, atrial fibrillation, and ventricular tachycardia. Diagnosis is usually made by echocardiogram, and although there is no gold standard, proposed echocardiographic criteria generally require prominent trabeculations with intertrabecular Doppler flow. One set of criteria requires a ratio of noncompacted to compacted myocardium greater than two (5). Once diagnosis has been made, it is recommended that first-degree relatives also undergo echocardiographic evaluation. Prognosis depends on the severity of disease at the time of presentation: those who present with severe heart failure or cardiac complications are at the highest risk for future cardiovascular death or heart transplantation. Other common complications include ventricular arrhythmias requiring implantable cardioverter-defibrillator (ICD) placement, progression of heart failure, and thromboembolic events. However, asymptomatic patients diagnosed incidentally or via screening appear to develop fewer complications and have an overall good prognosis (5). Controversial points include whether use of anticoagulation and placement of an ICD for primary prevention should follow standard cardiac guidelines or a more lenient criteria in those with LVNC.

TUBULOINTERSTITIAL NEPHRITIS AND UVEITIS (TINU) SYNDROME IN AN ELDERLY ADULT Xu Wu¹; Samer Nasser^{2,1}. ¹Conemaugh Memorial Medical Center, Johnstown, PA; ²Kidney Center, Johnstown, PA. (*Tracking ID #1934322*)

LEARNING OBJECTIVE 1: Tubulointerstitial nephritis and uveitis (TINU) syndrome is a rare autoimmune disorder that mainly affects young women and adolescents with a median age of 15 years. No identifiable risk factors have been found in most of cases although prior infection or the use of antibiotics and nonsteroidal anti-inflammatory drugs have been implicated in some instances. First described in 1975, most cases have since been documented in ophthalmology and pediatric medical literature and very rarely has it been reported in the older population.

CASE: We report a 60-year-old female patient who was referred to the Renal Clinic by her primary care physician for elevated serum creatinine together with uncontrolled hypertension. She had fever and fatigue with red and painful eyes. However, she did not have any recent history of infection or newly prescribed

analgesic medications. The patient's initial blood work revealed a Creatinine of 2.3 (baseline of 1.0) and subnephrotic range proteinuria and hematuria. The work up of the proteinuria and hematuria revealed normal complement levels, negative antinuclear antibody, myeloperoxidase, proteinase-3, hepatitis panel, and glomerular basement membrane antibodies. Ophthalmology referral for eye pain revealed uveitis for which she was treated with systemic and topical steroids for her eye symptoms. A kidney biopsy was done and showed an interstitial inflammatory process associated with tubulitis, which was consistent with active tubulointerstitial nephritis. Given the kidney biopsy results and the uveitis, she was diagnosed with TINU syndrome. This patient was treated with prednisone 1 mg/kg daily for 3 months followed by a tapering dose. Her renal function recovered without recurrence and she followed up with her ophthalmologist regarding the uveitis.

DISCUSSION: This case illustrates one of the few older patients who developed TINU syndrome, and whose kidney function successfully recovered after a course of steroid treatment. Noticeably, we did rule out certain autoimmune diseases relatively commonly seen before the diagnosis of TINU syndrome owing to some overlapping manifestations. Thus, this case delineates the importance of extensive system review in renal disease as well as the importance of appropriate referral and collaboration between specialties to obtain the correct diagnosis that dictates the appropriate management.

TUBULOINTERSTITIAL NEPHRITIS AND UVEITIS SYNDROME COMPLICATED BY IGA NEPHRITIS Takahiro Tsushima; Christine Kwan. Teine Keijinkai Hospital, Sapporo, Japan, Sapporo, Japan. (*Tracking ID #1930167*)

LEARNING OBJECTIVE 1: Recognize that tubulointerstitial nephritis and uveitis syndrome (TINU) with IgA nephritis (IgAN) can occur in the presence of Graves disease

CASE: A 64 years old Japanese woman presents with sore throat and hematuria $\times 3$ days. She describes urinating several tablespoons of blood/time, but no dysuria, frequency, or urgency. She reports elevated temperature (37.5°C), chills, and fatigue. All other review of systems shows no abnormalities. Besides Graves disease, she has hypertension and chronic kidney disease stage III and takes propylthiouracil, amlodipine, and candesartan; she has no allergies. She has never smoked or used recreational drugs and only occasionally drinks beer. She has no family history of kidney diseases. On physical examination, her vital signs show temperature 37.1°C, heart rate 94, blood pressure 115/80, respiratory rate 12, and O₂ saturation 98 % room air. On head and neck exam, her oropharynx is erythematous with swollen tonsils and pus; she has multiple tender, mobile, 5 mm bilateral cervical lymphadenopathy. Her thyroid, chest, and abdominal exams show no abnormalities, as does the rest of her exam. On her labs, significant values include white blood cell 23,310/ μ L, blood urea nitrogen (BUN) 15.4 mg/dL, and creatinine (Cr) 1.4 mg/dL (baseline); thyroid function panel is within normal limits. Rapid Strep Testing is positive with Streptococcus pyogenes on throat culture for which she is given ceftriaxone. Urinalysis with microscopy reveals heme >100/high power field and dysmorphic red blood cells but no proteinuria. Two weeks later, though, she develops bilateral ciliary injection and photophobia; slit lamp exam reveals anterior chamber uveitis. Labs show BUN 26 mg/dL and Cr 2 mg/dL; anti nuclear antibody is 1:320 and IgA 497 mg/dL (normal 90–400 mg/dL). Urinalysis reveals protein 3200 mg/day and β 2-MG 1347/ μ L (normal 0–250/ μ L). Kidney biopsy shows 1 cellular crescent, increased mesangial cell proliferation, and deposition of IgA and C3 in the glomeruli, consistent with IgAN. The interstitium, however, shows edematous changes and infiltration of granular leukocytes. Given her diagnosis of TINU syndrome complicated by IgAN, she is given methylprednisolone $\times 3$ days with subsequent oral prednisolone $\times 2$ months with clinical improvement.

DISCUSSION: TINU syndrome, with onset usually in women <20 years old, is associated with systemic symptoms of mild fever, weight loss, and fatigue. Renal manifestations include sterile pyuria, hematuria, proteinuria (<3 g protein/24 h), and acute renal failure. Typical biopsy findings include interstitial edema and infiltration by inflammatory cells, as the above patient. IgAN, however, is defined as glomerular nephritis resulting from IgA and C3 deposition around mesangial areas. It can present with mild fever, fatigue, mild proteinuria (300–1000 mg/day), hematuria, and upper respiratory infection symptoms. Rarer associations include dermatitis herpetiformis, seronegative arthritis, and inflammatory bowel disease. Only several case reports, however, have shown TINU complicated by IgAN; even still, most of them occur in the presence of the autoimmune diseases, spondyloarthritis and primary biliary cirrhosis. No reports have yet shown a relationship between Graves disease, such as the above patient, with TINU+IgAN. Given this possible association, even in those who are clinically euthyroid, one should recognize the possible renal complications of Graves disease.

TUMOR-INDUCED OSTEOMALACIA CAUSED BY A FGF-23 PRODUCING MESENCHYMAL TUMOR Sophia Hu¹; Sara Lubitz². ¹Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; ²Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ. (*Tracking ID #1930552*)

LEARNING OBJECTIVE 1: To recognize tumor-induced osteomalacia (TIO) as a rare and reversible form of osteomalacia and hypophosphatemia caused by a fibroblast growth factor 23 (FGF-23) producing mesenchymal tumor.

CASE: A 52 year-old female was in good health until after her first pregnancy in 1986, when she developed muscle cramps with exercise. Over a few years, these cramps became debilitating myalgias, and she developed a waddling gait. Initial labs showed serum phosphate 1.2 mg/dL, calcium 8.4 mg/dL, urine phosphate 1506 g/24 h (normal 400–1300), 25-hydroxyvitamin D 37 pg/mL, 1,25-dihydroxyvitamin D 60 pg/mL (normal 15–75), and mid-molecule PTH 379 pg/mL (normal 50–330). No glycosuria nor aminoaciduria were noted. Neutra-Phos 4 g daily and calcitriol were initiated. Transiliac crest bone biopsy findings were consistent with severe osteomalacia, at which time she was diagnosed with vitamin D-resistant hypophosphatemic osteomalacia. She continued to have symptoms of bone pain, myalgias, fatigue and depression, with elevated creatinine to 2.8 mg/dL. She also remained hypophosphatemic to 1.6 mg/dL despite daily phosphate and calcitriol replacement. About 20 years after initial presentation, she noted a mass on her right forearm. A PET scan of the mass showed hypermetabolic activity at that site. In November 2009, she underwent resection of the mass with pathology showing phosphaturic mesenchymal tumor 4.5×3.5×2 cm, mixed connective tissue variant. Subsequently, her phosphate levels gradually increased to 3.2 mg/dL, creatinine improved to 1.5 mg/dL, and urine phosphate normalized to 948 mg/24 h. FGF-23 was measured to be 157 RU/mL (normal <180), however there were no preoperative values for comparison. In March 2011, she was titrated off all phosphate supplements and phosphate levels have remained normal.

DISCUSSION: TIO is a rare acquired disorder characterized by osteomalacia and severe hypophosphatemia. In this recently described disease, mesenchymal tumors produce FGF-23, a phosphaturic hormone which inhibits renal phosphate reabsorption and reduces renal 1,25-dihydroxyvitamin D production, resulting in hypophosphatemia, phosphaturia and eventual osteomalacia. The pathways involved and clinical presentations are similar to the inherited forms of vitamin D resistant rickets, which include X-linked hypophosphatemic rickets (XLH) and autosomal dominant hypophosphatemic rickets (ADHR). In all of these conditions, phosphate and calcitriol replacement are the cornerstone of treatment. However, unlike XLH and ADHR, TIO is acquired and can potentially be reversed once the FGF-23 producing tumor is localized and resected. In our case of TIO, the patient's hypophosphatemia and osteomalacia completely resolved with tumor resection. Interestingly, 20 years had elapsed between the initial presentation and the discovery of this rare FGF-23 producing mesenchymal tumor.

TWO IS BETTER THAN ONE: PRESENTING WITH TWO PRIMARY MALIGNANCIES Adam Schwartz. NYP/Cornell, New York, NY. (*Tracking ID #1926346*)

LEARNING OBJECTIVE 1: Recognize unusual but treatable presentations of malignancy

LEARNING OBJECTIVE 2: Correlate anatomy and oncology

CASE: Patient is a 68 year-old woman with a significant tobacco history who initially presented to an outside hospital in December of 2012 with bronchitis. During that hospital stay she was found to be anemic. At New York-Presbyterian Hospital, patient underwent a colonoscopy which demonstrated invasive adenocarcinoma in the ascending colon. Subsequent PET CT revealed two lung nodules in the right upper lobe but with sparing of the liver. The lack of liver involvement suggested that the liver nodules may represent a distinct malignancy, indicating that both the colon and lung malignancies would be amenable to separate interventions and possibly carry a superior prognosis compared to that of metastatic colon cancer. Fine needle aspiration biopsy of one of the lung nodules was performed, which revealed squamous cell carcinoma. Patient underwent complex right hemicolectomy and subsequently received radiation therapy for her lung cancer. Patient remains alive at this time and still receives her care at New York-Presbyterian.

DISCUSSION: Though seemingly counterintuitive, this patient's prognosis was improved when the pulmonary nodule seen on PET CT was found to be a second primary malignancy. Had the nodule represented widely metastatic colon cancer, her options for surgical cure would have been greatly diminished. Instead, she was found to have two intervenable malignancies. The decision to biopsy the lung—rather than to attribute the nodule to metastatic colon cancer—was driven by the absence of metastatic lesions in the liver. Because blood flow from the colon passes through the liver on the way back to the heart, it would be highly unusual to have colon cancer metastasize to the lungs without also seeding the liver.

UH OH, THAT'S HIGH Ryan Brown, Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1924906*)

LEARNING OBJECTIVE 1: Review indications for high-dose versus low-dose methotrexate treatments.

LEARNING OBJECTIVE 2: Recognize signs, symptoms and treatment of methotrexate toxicity.

CASE: A 66 year old woman was admitted to the hospital for methotrexate chemotherapy. She had a history of diffuse large B cell lymphoma previously treated with four cycles of R-CHOP therapy along with two cycles of methotrexate and leucovorin. A third cycle of methotrexate treatment was initiated in the hospital. After a few days the patient developed clinical toxicity characterized by altered mentation, increased creatinine from 0.9 to 4.3, increased AST and ALT and pancytopenia with a low reticulocyte count. Twenty-four hours post-transfusion, her serum methotrexate level was elevated at 46. The methotrexate level remained elevated at 48 h and 72 h, with levels of 15 and 6, respectively. On the fifth day of hospitalization, the rescue drug Glucarpidase was given. A second dose was given on hospital day eight. Subsequently, the creatinine, AST, ALT, pancytopenia and altered mental status all began to improve. By discharge on hospital day 32, all evidence of methotrexate toxicity had resolved.

DISCUSSION: Methotrexate is a folate antagonist that has anti-proliferative, anti-inflammatory and immunomodulating effects; it is used for multiple causes. At higher dose levels (>500 mg), it is used mainly to treat hematologic malignancies. However, it is also used in the treatments of breast, gastrointestinal and head and neck cancers. At lower doses (weekly doses of 7.5 to 25 mg), it is commonly used for treatment of rheumatoid arthritis, psoriasis, systemic lupus erythematosus, crohn's, ectopic pregnancy, multiple sclerosis and many others. In this case, methotrexate in conjunction with the folic acid analog leucovorin, had been used twice previously for treatment of diffuse large B cell lymphoma. On the third round of this treatment, the patient developed toxic effects. Common side effects of high dose methotrexate are nephrotoxicity and hepatotoxicity. When giving methotrexate at these levels, aggressive pre- and post-administration treatment with intravenous fluids, urinary alkalinization and leucovorin should be performed. If the patient develops nephrotoxicity, plasma methotrexate levels will remain elevated. At this point, an anti-methotrexate agent is necessary. Other side effects of high dose methotrexate are encephalopathy, stomatitis, and drug rash. Hematologic adverse effects are more common with low dose methotrexate, although the patient in this case developed bone marrow suppression with high-dose therapy. With long-term low dose oral therapy, hypersensitivity pneumonitis can also occur. Treatment for methotrexate toxicity is Glucarpidase. It is a recombinant bacterial enzyme that converts methotrexate to inactive metabolites. It is needed when renal clearance of methotrexate has been compromised resulting in elevated plasma levels causing systemic effects. If the methotrexate level is still greater than 10 at 48 h, then glucarpidase should be given. It will decrease the level by 98 % in 30 min. It is rare but a second dose may be needed, as in this case.

UNCOMMON CAUSE OF COMMON PROBLEM: TESTICULAR TUMOR LEADING TO GI HEMORRHAGE Naba R. Mainali; Madan R. Aryal; Anthony Donato. Reading Health System, West Reading, PA. (*Tracking ID #1934053*)

LEARNING OBJECTIVE 1: To be able to identify a rare cause of GI bleeding secondary to testicular tumor metastasis in an appropriate setting.

LEARNING OBJECTIVE 2: To describe the diagnosis and management of the metastatic disease of testicular germ cell tumor.

CASE: Introduction: Testicular tumors are the most common solid tumors in young adult males, usually presenting with painless solid testicular mass. Germ cell tumors, the most common pathology, have high propensity of distant metastasis. Common sites of metastasis of testicular carcinoma include brain, lungs and liver. Hemorrhagic metastasis to stomach is a rare entity and represents bad prognostic sign. Case Report: A 24 year old male with recent diagnosis of mixed germ cell testicular tumor metastatic to lungs was admitted to the hospital for the evaluation of fatigue and black stool per rectum. He had been treated with orchiectomy and started on chemotherapy with BEP (Bleomycin, Etoposide and Cisplatin). Review of systems was otherwise negative. On physical exam, his blood pressure was 98/64 mmHg. He had pallor on the conjunctiva, but examination was otherwise non-focal. Laboratory studies revealed hemoglobin 7.8 g/dL, hematocrit 24.2 %, platelets 372,000/cmm³ and hemoccult testing was positive. Beta Human Chorionic Gonadotropin was 52322 MIU/ML (normal 0–5 MIU/ML) and Alpha Feto Protein was 27.6 ng/ml (normal: 0.0–14.9 ng/ml). He was given packed red blood cell transfusions, and an urgent Esophagogastroduodenoscopy revealed a single gastric ulcer along the anterior body of the stomach. The ulcer was biopsied, and showed a mixed germ cell testicular tumor metastatic to the stomach. Chemotherapy with BEP was continued and his hemoglobin became 11.1 g/dL. After the second cycle of chemotherapy, his beta HCG became 100 MIU/ML and AFP dropped to 2.6 ng/ml.

DISCUSSION: The accurate diagnosis of gastrointestinal bleeding secondary to testicular carcinoma metastasis requires high index of suspicion with

esophagogastroduodenoscopy and biopsy of the lesion. With the introduction of cisplatin based chemotherapy, metastatic tumor represents highly curable malignant disease. The combination of bleomycin, etoposide and cisplatin (BEP) given at 3-week interval still remains the treatment of choice for the metastatic disease of testicular germ cell tumor.

UNCOMMON PRESENTATION OF DIGOXIN TOXICITY IN SETTING OF ACUTE ON CHRONIC KIDNEY DISEASE AND AGGRESSIVE DIURETIC USE REQUIRING URGENT TREATMENT Hirokazu Ban; Maurice Rachko; Madeeha Saeed. Beth Israel Medical Center, New York, NY. (*Tracking ID #1922264*)

LEARNING OBJECTIVE 1: Recognizing that digoxin toxicity can cause life-threatening arrhythmia, like ventricular tachycardia which may require urgent Digibind treatment.

LEARNING OBJECTIVE 2: Recognizing that diuretics use can lead to digoxin toxicity.

CASE: We present a case of an 85 year-old man with past medical history of dilated non-ischemic cardiomyopathy (ejection fraction of 15 %), non-sustained ventricular tachycardia (NSVT) with automatic implantable cardioverter defibrillator (AICD), atrial fibrillation on coumadin, stage IV chronic kidney disease. Patient was recently discharged from another hospital after being treated for a non-ST elevation myocardial infarction (NSTEMI) where he was started acutely on digoxin and his furosemide dose was increased from 40 mg po twice a day to 80 mg po twice a day and metolazone 2.5 mg po daily was added to treat his heart failure. The patient's chief complaint was only decreased appetite. He presented to an outpatient clinic with alarming AICD and was found to have had multiple episodes of defibrillator shocks for sustained ventricular tachycardia that did not respond to antitachycardia pacing. The patient was admitted to the coronary care unit. His vital signs were all within normal limits and his physical exam was significant for irregularly irregular heart sound with III/VI holosystolic murmur at right sternal border. Initial lab results were significant for creatinine of 3.36 mg/dL (baseline 2.6 mg/dL), serum digoxin level of 2.2 ng/mL (goal 0.5–0.9 ng/mL), potassium of 4.0 meq/L, magnesium of 2.4 mg/dL, and troponin I of 0.157 ng/mL. Chest x-ray revealed cardiomegaly with small right pleural effusion and his ECG showed polymorphic NSVT. Digoxin toxicity was suspected and the patient received 4 vials of digoxin-specific Fab fragments. The polymorphic NSVT resolved after the dose of digoxin-specific Fab fragments. Due to his acute kidney injury, enalapril, furosemide, metolazone were held. On hospital day 2, patient remained free of any further NSVT episodes and was transferred to a telemetry floor for continuous monitoring. His creatinine improved to 2.19 mg/dL near baseline and the patient was discharged with cardiology follow up on hospital day 4.

DISCUSSION: Digoxin is commonly used to treat atrial fibrillation and congestive heart failure. Its well known cardiac side effects include increased automaticity and decreased AV node conduction such as atrial tachycardia with complete AV block and bidirectional ventricular tachycardia which has been related to higher mortality. Often digoxin toxicity occurs in the setting of aggressive diuresis, as in our patient. Due to the narrow therapeutic range of digoxin and the significant overlap between therapeutic and toxic ranges, even slight elevations of digoxin levels can cause acute digoxin toxicity. This is especially problematic among patients with advanced heart disease, underlying atrial fibrillation (suggestive of diseased myocardium at risk), and renal failure. These risks are potentiated by use of increasing diuretic dosages without adequate monitoring. Given these adverse effects, the use and dosage of digoxin routinely have declined in general cardiology practices. Digoxin toxicity is now seen infrequently and acute hospitalizations have declined, however, it must remain on the differential as the potential culprit when patients with above-mentioned diseases on digoxin present with cardiac arrhythmias. Recognizing digoxin toxicity is paramount in treating it adequately. In this case, the patient was urgently treated with digoxin-specific Fab fragments and withholding nephrotoxic agents with good results.

UNCOMMON SEPSIS FOLLOWING PANCREATIC SURGERY Arvind Kalyan Sundaram^{1,2}; Carey C. Thomson^{1,2}. ¹Mount Auburn Hospital, Cambridge, MA; ²Harvard Medical School, Boston, MA. (*Tracking ID #1939655*)

LEARNING OBJECTIVE 1: To recognize Aeromonas Hydrophilia infection as a rare cause of sepsis with respiratory failure

CASE: 69 Year old male was admitted to the Intensive Care Unit (ICU) after developing fever and hypotension following an elective pancreatectomy for a pancreatic adenocarcinoma. Prior to the admission patient was evaluated for painless jaundice. On hospital day two, he developed several episodes of fever to 102 F and hypotension requiring vasopressors. After obtaining blood, urine, sputum and abdominal drainage culture, he was treated with broad spectrum antibiotics including Vancomycin, Levofloxacin and Metronidazole. Despite this coverage, he continued to

have fevers and remained hypotensive, ultimately requiring large volume fluid resuscitation and multiple vasopressors to maintain a blood pressure, and mechanical ventilation for respiratory support. His past medical illness is significant for Hypertension and Gastroesophageal reflux disease. He was Armenian born and lived there as an adult, and had a prior history of heavy alcohol use. Examination did not reveal any sources of infection. Labs were significant for white blood cell count of 21,000 cells/mm³ with a band of 11 %, Hematocrit of 37 %, Platelet of 70,000/mm³, Elevated Alanine transaminase and Aspartate transaminase of 55 IU and 58 IU respectively, Amylase of 805 units/l and lipase of 1300 units/l. Serum chemistry and coagulation profiles were within normal limits. Chest radiograph showed mild congestion and large bilateral pleural effusions, Computed Tomography scan of abdomen and pelvis revealed a stable sub-capsular hematoma and was otherwise unremarkable. Jackson Pratt (JP) abdominal drain and sputum cultures grew gram negative bacilli which were later speciated as *Aeromonas Hydrophilia*. The JP drain also grew *Sphingomonas Paucimobilis*. The blood cultures and urine culture were negative. Patient gradually improved and was later extubated. He completed a total of 14 day course of Levofloxacin and was discharged to acute rehabilitation center for recovery.

DISCUSSION: *Aeromonas* infections in humans are rare and are more commonly seen in immune-compromised host including cirrhosis and malignancy. Among the 14 different *Aeromonas* spp., *A. Hydrophilia*, *A. caviae* and *A. sobria* account 80–90 % of the human isolates. These three species are commonly involved in *aeromonas* infections causing cellulitis, septicemia, meningitis, myositis, peritonitis, gastroenteritis, respiratory tract infections, hemolytic uremic syndrome and hepatobiliary disease. *Aeromonads* are gram negative, non-spore forming, facultative anaerobic bacilli that produces beta-lactamase and are extensively distributed in the environment through soil, water and are present in contaminated meat including chicken and ground beef. The bacteria can be acquired through wound contaminated with soil and water containing *Aeromonad* spp., consumption of contaminated water or meat or through medicinal leech therapy. The most common portal of entry of *A. Hydrophilia* causing bacteremia or sepsis in patient is through the gastrointestinal tract and skin lesions. Though the incidence is low, mortality rate of *Aeromonas* bacteremia or septicemia is around 70 %. Studies have shown that *Aeromonas* bacteremia have high acute mortality and should always be considered as one of the pathogens that can cause sepsis in patient with cirrhosis or neoplasm. Penicillin and first generation Cephalosporin are inherently resistant to *Aeromonas* species and the most effective antimicrobial includes Fluoroquinolones, Carbipenems and third generation Cephalosporin.

UNHAPPY FEET: VORICONAZOLE ASSOCIATED TOXIC PERIPHERAL NEUROPATHY Jayanth Adusumalli; Abhishek Singla; Avyakta Kallam; Edward Horowitz. Creighton University Medical Center, Omaha, NE. (*Tracking ID #1900481*)

LEARNING OBJECTIVE 1: To recognise that chronic Triazole therapy can be the primary cause of peripheral neuropathy.

LEARNING OBJECTIVE 2: To discuss management of this potentially irreversible complication.

CASE: A 53 year old male was diagnosed with rare invasive *Aspergillus* infection of the heart. He underwent mass resection of the right ventricle along with tricuspid valve replacement and was started on long-term voriconazole therapy. His past medical history included allergic bronchopulmonary aspergillosis, IgA deficiency and hypertension. Approximately 1 year after starting voriconazole, he complained of progressively increasing numbness, tingling and weakness of both his feet to the point where he found it difficult to walk. Neurological examination: Motor exam revealed power of 5/5 in all muscle groups along with 2+ deep tendon reflexes. Sensory exam revealed diminished fine touch and vibration sense in the feet, the left side being more involved than the right, along with loss of proprioception in the first and second toe on the left side. Laboratory tests revealed that the patient's Hemogram, electrolytes, Vit. B 12 level, TSH, MMA, SPAP were all within normal limits. Voriconazole serum levels throughout therapy were all within the therapeutic range. Voriconazole was discontinued in favor of posaconazole. This resulted in marked improvement of symptoms over 2 months. On the basis of the temporal relationship of PN to the initiation of voriconazole therapy and subsequent improvement on cessation in the absence of other etiologies, a diagnosis of voriconazole induced PN was made.

DISCUSSION: Triazole antifungals have been known to potentiate PN caused by other agents such as vincristine, but are now being recognized as primary causes of peripheral neuropathy, with both short term and long term use. Symptoms may be sensory, motor or both. The mechanism is still under debate. One recent study claimed incidence of PN with chronic triazole therapy without any other contributing factors to be as high as 10 %, itraconazole being the most frequent culprit. It is important for physicians to be aware that chronic triazole therapy can be the primary cause of PN as it is rare, potentially irreversible and can manifest even with therapeutic serum levels as in our patient. Management includes complete

neurological exam at initiation of therapy and subsequent follow up to catch it early, switching the anti-fungal agent preferably to a non-triazole if neuropathy manifests.

UNPREDICTABLE NATURE OF TOLVAPTAN IN THE TREATMENT OF HYPERVOLEMIC HYponATREMIA Ishan Malhotra; Kalyan Janga; Sheldon Greenberg; Shilpa Gopinath. Maimonides Medical Center, Brooklyn, NY. (*Tracking ID #1937102*)

LEARNING OBJECTIVE 1: Severe chronic hyponatremia must be managed with extreme care especially in patients with chronic debilitating illness. Rapid re-induction of hyponatremia immediately after the diagnosis of Osmotic Demyelinating Syndrome (ODS), within 24–36 h, can reverse the symptoms of ODS and is the treatment of choice.

LEARNING OBJECTIVE 2: Tolvaptan should be only dosed after checking Serum sodium levels .

CASE: A 51 year old male who presented with congestive heart failure exacerbation on admission had a serum sodium of 122 mmol/lt. Patient was fluid restricted and aggressive diuresis was done and as there was no rise in serum sodium levels, Tolvaptan 15 mg was started on hospital day 6. Patient showed improvement after receiving the first dose of Tolvaptan and on hospital day 7 his serum sodium was 126 mmol/L. On day 8 he had a rapid increase in his serum sodium level from 126 mmol/lt to 142 mmol/l after he received the second dose of Tolvaptan. His serum sodium levels further increased from 159 mmol/L to 167 mmol/L on day 8. At this point, tolvaptan was stopped. The patient developed signs of osmotic demyelination syndrome which failed to resolve after rapid correction with hypotonic fluids and desmopressin and was transferred to the medical intensive care unit for further management of hypernatremia.

DISCUSSION: Rapid correction of hyponatremia with tolvaptan can cause osmotic demyelination syndrome (ODS). In susceptible patients, including those with severe malnutrition, alcoholism or advanced liver disease, slower rates of correction may be advisable. Slow correction of serum Na (less than 12 mmol/L/day) is recommended to prevent the emergence of this syndrome (1). There is no standard therapy once ODS sets in. Fluid should not be restricted in patients with hyponatremia who are started on Tolvaptan and serum sodium concentration should be monitored every 6–8 h in order to avoid rapid correction of sodium levels (2) along with frequent urine output monitoring. Rapid re-induction of hyponatremia with hypotonic fluids like 5 % dextrose water and half normal saline along with desmopressin has been shown to improve mortality and even reverse the signs and symptoms of ODS and is currently the favored strategy to treat patients with ODS due to hypernatremia. The present case tells us that severe chronic hyponatremia must be managed with extreme care especially in patients with chronic debilitating illness due to the unpredictable nature of tolvaptan to raise serum sodium levels. In most hospital settings, warfarin dosing happens after checking daily prothrombin time. Similarly tolvaptan should be administered after checking serum sodium levels for that day and it should not be started as a standing order while initiating treatment. References 1. Rockville, MD: Otsuka America Pharmaceutical, Inc.; May, 2009. Samsca (tolvaptan), package insert. 2. Schrier RW, Sharma S, Shchekochikhin D Nat Rev Nephrol. 2013 Jan; 9(1):37–50.

UNUSUAL EARLY MALIGNANT TRANSFORMATION IN PANCYTOPE-NIA: CASE REPORT AND DISCUSSION Dinuli H. Delpachitra; Cherian Verghese. University of Toledo, Health Sciences, Toledo, OH. (*Tracking ID #1930082*)

LEARNING OBJECTIVE 1: Recognize early transformation of hypoplastic bone marrow to acute myeloid leukemia.

CASE: A 74 year old woman with a past medical history of hypertension, osteoarthritis and anxiety disorder presented with fatigue and generalized weakness lasting a few weeks. On physical examination she was thin but in no acute distress. Her initial blood work showed pancytopenia with a hemoglobin of 6.1 g/dL, white blood cell count of $1.5 \times 10^3/\text{mm}^3$, platelet count of 16,000/mm³. In comparison, a previous complete blood count revealed a hemoglobin of 12.4 g/dL, white blood cell count of $3.7 \times 10^3/\text{mm}^3$, and a platelet count of 133,000/mm³. At the time of presentation, her medications included atenolol, lorazepam, and multiple daily vitamins. Her history was negative for any recent infections or new medications. Peripheral blood smear did not reveal any blasts. Bone marrow biopsy was consistent with an aplastic marrow with rare ringed sideroblasts. Myeloid blasts were <5 %. The paroxysmal nocturnal hemaglobinuria panel by flow-cytometry was negative. Cytogenetic studies demonstrated deletion of 17q. Molecular studies however, were negative for FLT3 gene mutation. A repeat complete blood count after 2 weeks demonstrated persistent pancytopenia but with 23 % percent blasts in the peripheral

blood. Bone marrow biopsy was repeated to address the concern of leukemic transformation and it showed 32 % blasts. Immunophenotype analysis showed an abnormal myeloblast population expressing CD13, CD34, HLA-DR and CD11b. The cells lacked expression of CD33, CD9, CD71, and CD117. These findings were consistent with acute myeloid leukemia transformation.

DISCUSSION: The risk of transformation to Acute Myeloid Leukemia (AML) is generally considered to be less likely with hypoplastic MDS. Several clinical, morphological and chromosomal factors have been studied to develop a system of predicting leukemic transformation in MDS patients. The Revised International Prognostic Scoring System (IPSS-R) was published in 2012 as a valid tool to predict survival and risk of transformation to AML. However, its validity in predicting transformation in a hypoplastic marrow is unclear. Several causes of leukemia in a pancytopenic marrow exist and include hairy cell leukemia, hypoplastic MDS, myelofibrosis and paroxysmal nocturnal hemoglobinuria. Non-malignant causes of pancytopenia are well known and include medications, radiation, Systemic Lupus Erythematosus and infections such as Malaria and MiliaryTB. Our patient had Acute Myeloid Leukemic transformation within weeks of her diagnosis. Such rapid evolution is not predicted by the available IPSS-R risk stratification. Since our patient presented with an abnormal myeloblast population expressing CD13, CD34, HLA-DR and CD11b, we can postulate that the appearance of mutations like 17q deletion may be predictive of aggressive behavior in a hypoplastic marrow. Cytogenetic abnormalities are considered unlikely with benign causes of pancytopenia. Early recognition of this transformation is crucial as selected patients may benefit from enrollment in clinical trials.

UNUSUAL HEADACHE - UNUSUAL CAUSE: DURAL SINUS THROMBOSIS DUE TO MTHFR DEFICIENCY Shah Habib; Mashrafi Ahmed. Texas Tech Univ Health Science Center, Amarillo, TX. (*Tracking ID #1938999*)

LEARNING OBJECTIVE 1: Recognize dural venous sinus thrombosis as an unusual but life threatening cause of headache

LEARNING OBJECTIVE 2: Methylenetetrahydrofolate reductase (MTHFR) is a rare prothrombotic state associated with dural sinus thrombosis

CASE: A 29 year old young Caucasian female presented with persistent, sharp and stabbing headache over the front and back of her head for 6 weeks. It started suddenly, and was excruciating in intensity. She had no history of oral contraceptive pill use, but had history of migraine headache which was different from this episode. She had few episodes of nausea and vomiting with some tingling sensation at the distal upper limbs, and mild paresis of the right 6th cranial nerve on presentation. On ophthalmoscopic examination she had mild blurring of the temporal side of the optic disc with intact venous pulsation. MRI brain revealed thrombosis of the sagittal sinus extending into the right transverse sinus. Initial workup for prothrombotic defects, infection, malignancy and pregnancy were negative. Further extensive workup revealed MTHFR deficiency and high homocysteine level. The patient was treated with enoxaparin bridged with warfarin.

DISCUSSION: Dural sinus thrombosis is uncommon, with an overall incidence of <1 per 100,000 cases annually. The disorder is more common in neonates and children than in adults, and among young adults more common in women than men. The mean age of onset is 39 years. The major risk factors for dural sinus thrombosis in adults are prothrombotic conditions, oral contraceptives, pregnancy and the puerperium, malignancy, infection, head injury, and mechanical precipitants. The clinical presentation of dural sinus thrombosis is highly variable. The onset can be acute, sub-acute, or chronic. Headache (of gradual, acute, or thunderclap onset) is the most frequent symptom, occurring in almost 90 % of patients, and may occur as a part of an isolated intracranial hypertension syndrome, with or without vomiting, papilledema, and visual problems. Head CT scan is normal in up to 30 % of dural sinus thrombosis cases, and most of the findings are nonspecific. Brain MRI in combination with MR venography is the most sensitive examination technique for demonstrating the thrombus and the occluded dural sinus or vein. Although a 2010 meta-analysis by Gouveia Lo, et al. did not show MTHFR deficiency as a risk factor for dural venous thrombosis, but in our case, it was the inciting factor. Treatment for dural sinus thrombosis is anticoagulation with low molecular weight heparin bridged with warfarin. Warfarin should be continued 6–12 months.

UNUSUAL PRESENTATION OF MAC INFECTION Tatyana Tarunukha; Eric R. Simon; Pinky Jha. Medical College of Wisconsin, Milwaukee, WI. (*Tracking ID #1930392*)

LEARNING OBJECTIVE 1: Recognize atypical presentation of MAC infection in an immunocompromised patient.

LEARNING OBJECTIVE 2: Review management of disseminated MAC.

CASE: 28 year old female with history of AIDS (previously on HAART) and pancytopenia presented as a direct admission for evaluation of elevated liver transaminases. Laboratory findings were significant for AST elevation of 964, ALT of 220, Alkaline phosphatase of 871, CD4 count of 8, WBC count of .5 and platelets of 87. On presentation, patient appeared comfortable and was not complaining of any symptoms. Physical exam and review of systems were unremarkable. Initially, all hepatotoxic drugs were discontinued and Infectious Diseases and Hematology were consulted for further treatment recommendations. Over the course of hospitalization, patient underwent an extensive microbiology work up as well as imaging of the abdomen, the hepatobiliary tree and biopsies of the bone marrow and liver. Results were significant for a positive AFB blood culture. Bone marrow biopsy showed non-necrotizing granulomatous inflammation with acid fast positive organisms and liver biopsy revealed granulomatous hepatitis with acid fast bacilli. Based on biopsy results and positive blood culture, disseminated MAC (DMAC) with multiorgan involvement was thought to be responsible for the pancytopenia as well as the hepatocellular liver injury. Azithromycin, Rifabutin, and Amikacin were chosen as triple therapy for DMAC as the patient had advanced AIDS with a low CD4 count. WBC count increased with Neupogen administration. During hospitalization patient continued to remain asymptomatic, however, her liver function tests significantly improved after the initiation of antibiotics.

DISCUSSION: Here, we present a patient with disseminated MAC causing granulomatous hepatitis and bone marrow suppression who has remained asymptomatic throughout her illness. DMAC is a life threatening infection caused by either *M. avium* or *M. intracellulare* that carries up to a three-fold risk of death in patients with AIDS. MAC infections typically affect the respiratory or GI tract and symptoms include fevers, night sweats, abdominal pain, diarrhea and weight loss. The infection is acquired through inhalation or ingestion of organisms from soil or water and can subsequently spread through the lymphatics in an immunocompromised host. DMAC typically occurs after the CD4 count drops below 50 cells/mm³ and in patients with CD4 counts of less than 10 cells/mm³, the yearly incidence rate has been reported to be as high as 39 %. First line agents for treatment are Clarithromycin and Azithromycin followed by Ethambutol and Rifabutin. IDSA guidelines suggest that at least two drugs should be initiated for the treatment of DMAC due to concern for development of resistance. In our patient, however, we elected to use a three drug therapy of Azithromycin, Rifabutin, and Amikacin due to the patient's severe immunocompromised state. Ethambutol was avoided due to patient's history of optic neuritis. Therapy will be continued for at least a year and until the CD4 count remains above 100 cells/mm³ for at least 6 months.

UNUSUAL SUSPECTS: RENAL SIDE EFFECTS OF PENICILLINS Cady Blackey Brown; Deepa Bhatnagar. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1926138*)

LEARNING OBJECTIVE 1: Illustrate a rare cause of hypokalemia

LEARNING OBJECTIVE 2: Review the various causes of nephrotoxic effects of antibiotics

CASE: A 46 year-old man with a history of hepatitis C cirrhosis and osteomyelitis of the humerus was sent from infectious disease clinic to the emergency department because of fatigue and weakness. He denied any dizziness, fever or chills. He denied hematemesis, hematochezia and melena. He denied any recent diarrhea and reported having normal oral intake. Two weeks prior he had been initiated on a regimen of nafcillin and rifampin for osteomyelitis. The physical exam revealed stable vital signs and a thin man with scleral icterus in no acute distress. The cardiovascular and lung exams were normal. The abdominal exam revealed mild ascites. The neurologic exam was normal, including normal gait and absence of asterixis. Laboratory results revealed a potassium level of 1.9 and magnesium of 1.8. All other electrolytes were normal and liver enzymes were at baseline. The electrocardiogram revealed flattened T waves. He required aggressive potassium repletion over the ensuing 48 h. However, discontinuation of nafcillin led to normalization of potassium. Supplementation of potassium was then stopped and the potassium level remained normal with symptomatic improvement.

DISCUSSION: Antibiotics are among the most frequently prescribed medications. However, their use is often limited by potential renal toxicity. Internists must make decisions regarding antibiotic therapy by weighing the potential side effects of a medication and the co-morbidities of the patient. A number of antibiotics are known to have renal side effects, particularly decreased glomerular filtration rate (GFR). Vancomycin, cephalosporins, amphotericin, aminoglycosides and bactrim all have the well-known risk of causing acute renal failure. Penicillins, on the other hand, are often a safe choice when considering renal side effects. However, penicillins can affect electrolyte, fluid and acid/base status through renal mechanisms even though they do not affect GFR. In particular, penicillins have been shown to cause hypokalemia. Within the principal cells of the collecting duct, penicillin acts as a non-reabsorbable anion. This causes a luminal negative

charge in the setting of increased aldosterone-driven sodium reabsorption. This negative charge stimulates potassium secretion and can cause severe hypokalemia, as was seen in this case. Since antibiotics are so commonly prescribed, it is important for internists to be familiar with the spectrum of renal side effects of these medications, not just their impact on GFR. This familiarity allows the cause of electrolyte, acid-base or fluid derangements to be identified and treated prior to the onset of significant morbidity.

URACEMIC SICK! Michael Jesinger; Diego F. Alcivar Franco; Andrew Hoellein. University of Kentucky, Lexington, KY. (*Tracking ID #1938763*)

LEARNING OBJECTIVE 1: Describe the presentation, clinical evolution, diagnosis and management of Tumor Lysis Syndrome.

LEARNING OBJECTIVE 2: Outline the approach to hyperuricemia, highlighting the importance of malignancy work up.

CASE: A 65 year-old man with a history of Chronic Kidney Disease Stage III and renal cell carcinoma status post left-sided nephrectomy 6 months ago, was admitted with altered mental status. He was found to have acute kidney failure with a creatinine of 5.5 mg/dL, hypercalcemia of 12 mg/dL, metabolic acidosis, and hyperkalemia. Despite volume resuscitation and naltrexone, his altered mental status persisted. Further evaluation found uric acid 18 mg/dL and phosphate 5.3 mg/dL. Our patient now met Cairo-Bishop criteria and was given rasburicase for hyperuricemia. However, suspicion for tumor lysis at this point was low given that the patient did not receive chemotherapy within the last month and extensive evaluation with peripheral smear, esophagogastroduodenoscopy, colonoscopy, CT of chest, abdomen, and pelvis, and whole body bone scan were without overt signs of tumor burden. Abdominal ultrasound showed irregular hepatic parenchyma concerning for cirrhosis. A transjugular liver biopsy was performed and revealed metastatic renal cell carcinoma which was likely the source of this tumor lysis syndrome. Despite improvement of uric acid to 4 mg/dL, his mental status continued to worsen and after discussion with family members, our patient was transferred to Hospice for comfort care.

DISCUSSION: Tumor lysis syndrome (TLS) is a catabolic disorder in the setting of malignancy with a high proliferative rate, large tumor burden, high sensitivity to treatment, chemotherapy, cytolytic antibody therapy, radiation therapy, or sometimes glucocorticoid therapy can result in the rapid lysis of tumor cells and is considered an oncologic emergency. It is most commonly observed in poorly differentiated lymphomas and leukemia especially in patients undergoing chemotherapy. However, TLS has been rarely described after treatment of nonhematologic solid tumors and in patients not undergoing cytotoxic therapy. Our review of the literature found no reports of renal cell carcinoma-induced TLS. Clinicians should have a high suspicion for tumor lysis syndrome in any patient with a history of malignancy and especially in those with renal compromise. The mainstay of treatment is prevention. Early recognition of TLS is crucial as its sequelae of electrolyte imbalances can result in potentially fatal cardiac arrhythmias or renal failure. The Cairo-Bishop score is based on laboratory changes of hyperuricemia, hyperphosphatemia, hyperkalemia and hypocalcemia and clinical changes of worsening renal function, seizures or changes in mental status and cardiac arrhythmias. Two laboratory and one clinical change is diagnostic. Patients at risk for tumor lysis should be treated prophylactically with allopurinol. In TLS, aggressive hydration and rasburicase often result in rapid improvement of renal function and resolution of symptoms. Allopurinol prevents uric acid from forming while rasburicase functions as a synthetic uric oxidase promoting degradation of uric acid.

URINOTHORAX AS A RARE CAUSE OF DYSPNEA Srividya Bhadriraju^{1,2}; Jeffrey T. Bates^{2,1}. ¹Baylor College of Medicine, Houston, TX; ²Michael E. DeBakey VA Medical Center, Houston, TX. (*Tracking ID #1939593*)

LEARNING OBJECTIVE 1: Recognize urinotorax as a rare cause of severe dyspnea in patients who have undergone recent urologic instrumentation

LEARNING OBJECTIVE 2: Understand the pathophysiology and diagnostic challenges of a urinotorax

CASE: A 62-year-old female with a history of aortic valve replacement on warfarin presented with increased urinary frequency and hematuria; an abdominal CT scan showed a right renal calculus. She was admitted and underwent a right percutaneous nephrolithotomy with placement of a percutaneous nephrostomy tube. On post-operative day eight, she complained of worsening dyspnea at rest associated with non-radiating substernal chest pain, mild nonproductive cough, orthopnea, and mild nausea. Physical examination revealed hypoxia to 82 % on room air, tachypnea, decreased breath sounds in the right lower lung field, and bloody output from the nephrostomy tube. The nephrostomy tube was removed, and a chest x-ray showed a

large right pleural effusion. The patient underwent a right thoracentesis with removal of 1.1 L of malodorous, bloody fluid. Pleural fluid analysis demonstrated a urine-like odor, low protein, an elevated LDH, and an elevated pleural fluid-to-serum creatinine ratio of greater than 1.0. She was diagnosed with urinotorax, and clinically improved after the thoracentesis.

DISCUSSION: Urinotorax results from an accumulation of urine in the pleural space. Initially, leakage of urine into the retroperitoneal space forms a urinoma; urine then moves directly into the pleural cavity due to either an anatomic diaphragmatic defect or via lymphatic drainage into the mediastinum. Although urinotorax commonly occurs ipsilateral to the obstructed kidney, it is rare in unilateral obstruction if the contralateral kidney function is normal. Pleural fluid analysis typically reveals an elevated pleural fluid-to-serum creatinine ratio (much greater than one), a low glucose, a low pH, and a transudative effusion. However, effusions are often misclassified as exudative due to the high LDH. A urinotorax is the only cause of a transudative pleural effusion with a low pH. Renal scintigraphy will demonstrate leakage of tracer from the urinary tract into the pleural space. Once the renal obstruction is relieved, the urinotorax typically resolves. Although obstructive renal disease is common, urinotorax is less frequently recognized. The diagnosis should be considered in patients with a pleural effusion in the setting of obstructive uropathy, trauma from urologic procedures (such as attempted percutaneous nephrostomy, kidney biopsy, or lithotripsy), urinary tract malignancy, or a renal transplant. Severe dyspnea, although present in this case, is uncommon and has been reported only a few times in the literature.

VENOUS AND ARTERIAL HYPERCOAGULABILITY AS PRESENTING MANIFESTATIONS OF PANCREATIC ADENOCARCINOMA Sudeep D. Thapa; Mohammed W. Imam; Lucero C. Chueca Villa. Henry Ford Hospital, Detroit, MI. (*Tracking ID #1926773*)

LEARNING OBJECTIVE 1: Recognize that pancreatic cancer related hypercoagulability can present as stroke, deep venous thrombosis and pulmonary embolism

LEARNING OBJECTIVE 2: Recognize that patients with new onset resistant diabetes mellitus may have pancreatic malignancy

CASE: A 58 years old African American male with history of smoking for 30 pack years, hypertension, STEMI, uncontrolled new onset diabetes mellitus, presented with transient speech and gait abnormality to the Emergency Department. He presented with history of slurring of speech and inability to 'think of the right words' while talking on the phone. He had no difficulty understanding what was being said to him. On presenting to the ED, new onset flattening of the left nasolabial fold was noted. Patient also reported right calf tenderness and mild swelling for 3 days. He also complained of a brief episode of chest discomfort which resolved spontaneously. He denied fever, headache, palpitations and weakness in his limbs. Of note, he also had a history of new onset uncontrolled Diabetes mellitus diagnosed 1 year prior and 30 lb weight loss in 3 months. He had consistently elevated HbA1c despite treatment. On investigations, mild elevation of troponin which peaked at 0.12 mcg/L was noted, there were no new ECG changes. CT scan of the head did not show any acute abnormalities. CT scan of the abdomen showed hypodense mass within the body tail junction of the pancreas measuring 4.8×3 cm and multiple masses were noted throughout the liver. Diffusion weighted MRI of the brain was done which showed an area of acute infarction involving the left frontal gyrus, punctate focus of acute infarction in the left centrum semiovale and punctate focus of acute early infarction in the right centrum semiovale. CT scan of the chest showed multiple small bilateral emboli and small left common femoral deep venous thrombosis. 2 D echocardiogram showed hypokinesis consistent with the patient's history of myocardial infarction. No intra-cardiac thrombus or vegetation was noted. A liver biopsy of the metastatic mass was done and histopathology confirmed pancreatic adenocarcinoma, strongly positive for CK7 and CK19 on immunostaining.

DISCUSSION: Malignancy is a hypercoagulable state and pancreatic adenocarcinoma in particular is associated with intravascular thrombosis. Reports of patients presenting with stroke as the initial manifestation of cancer have been published and bi-hemispheric disseminated multiple ischemic lesions are particularly suggestive of an underlying malignancy. Deep venous thrombosis is a well-known manifestation of cancer and precedes the diagnosis of malignancy in more than 7 % of the cases. Malignancies in general and adenocarcinomas in particular are associated with increased thrombogenicity both in the venous and arterial blood vessels. Both pancreatic neuroendocrine tumors and pancreatic adenocarcinoma are related to new onset treatment resistant diabetes mellitus. Cancer induced tissue damage leads to diabetes due to islet cell and beta cell destruction. Furthermore, patients with diabetes have been shown to have increased risk of pancreatic cancer. Therefore, diabetes can be both a potential cause and effect of pancreatic cancer. In summary, pancreatic cancer should be considered in patients presenting with new onset treatment resistant diabetes and also in patients presenting with thrombosis of the venous and arterial blood vessels.

VENTRICULAR FIBRILLATION ARREST IN A PATIENT WITH PRINZMETAL'S ANGINA Venkatesh Alapati; Francis Golier; Maria Sobolev. Montefiore Medical Center, Bronx, NY. (*Tracking ID #1937220*)

LEARNING OBJECTIVE 1: Identify ventricular fibrillation arrest and treat it appropriately

LEARNING OBJECTIVE 2: Recognize Prinzmetal's angina as a rare cause of ventricular fibrillation

CASE: A 57 year-old woman presented with sudden onset, severe substernal chest pain lasting 20 min. She was hypertensive (190/102 mmHg) with an otherwise unremarkable cardiac exam. Laboratory testing revealed elevation in troponin (0.3 ng/mL). Electrocardiogram demonstrated ST segment elevations in the inferior leads. During initial evaluation, the patient had a ventricular fibrillation arrest and immediately received chest compressions with one electrical defibrillation before return of sinus rhythm. She underwent emergent cardiac catheterization revealing normal coronary arteries without thrombus or occlusion. She was admitted to the Coronary Care Unit for further management. A diagnosis of Prinzmetal's angina was made based on the presenting ST segment elevations in the setting of angiographically normal coronary arteries. Calcium channel blockers were initiated to prevent subsequent coronary spasm. She had no further episodes of chest pain and was discharged home.

DISCUSSION: Ventricular fibrillation is the most frequent mechanism of sudden cardiac death. It is electrically characterized by rapid, irregular waveform with variable amplitude, which can ultimately evolve into asystole. Adult Cardiac Life Support (ACLS) protocols should immediately be initiated once ventricular fibrillation is recognized. If return of spontaneous circulation is achieved, the underlying cause of ventricular fibrillation should be investigated. Myocardial infarction and electrolyte imbalances are the most common causes of ventricular fibrillation. Coronary vasospasm, or Prinzmetal's angina, is a rare cause of myocardial infarction and ventricular arrhythmias. Prinzmetal's angina is typically characterized by cyclical, non-exertional, chest pain with associated ST-segment elevation on electrocardiogram. Episodes are triggered by coronary vasospasm. The prevalence of the disease is not well known. In the United States, 4 % of patients who undergo coronary angiography show evidence of focal spasm. While ST-segment elevations in the absence of coronary occlusion is suggestive of Prinzmetal's angina, provocative tests with potent vasoconstrictors (ergonavine or acetylcholine) can be used during angiography to make a definitive diagnosis. Calcium channel blockers and long-acting nitrates are effective chronic therapies for coronary vasospasm. Myocardial infarction and life-threatening arrhythmias occur in approximately 25 % of untreated patients with Prinzmetal's angina. Patients who experience an arrhythmic complication, especially ventricular fibrillation and sudden cardiac arrest, have a poor prognosis. Further investigation is warranted to determine if these patients will benefit from Automatic Implantable Cardioverter Defibrillators (AICD) or life vests as secondary prevention. Recognition and treatment of ventricular arrhythmias can save lives. Early recognition of Prinzmetal's angina allows for appropriate treatment and prevention of potentially fatal complications.

VISUAL LOSS AT THE HEART OF THE MATTER Laura Hart; Harish Jasti. University of Pittsburgh Medical Center, Pittsburgh, PA. (*Tracking ID #1925881*)

LEARNING OBJECTIVE 1: Recognize the presentation of a transient ischemic attack (TIA).

LEARNING OBJECTIVE 2: Utilize the American Heart Association (AHA) guidelines to perform a cost-conscious evaluation of a TIA.

CASE: A 58 yo female with a history of hypertension, type 2 diabetes, and obstructive sleep apnea presented after five episodes of transient right-sided visual field loss that occurred over the course of 2 days. During the episodes, she also noted associated zig-zag lines in her remaining visual fields, but felt that the visual loss respected the vertical (i.e. that her left visual field was preserved in both eyes). There was no associated numbness, tingling, vertigo, light-headedness, double vision, headache, or dysphagia. Review of systems was notable for dyspnea on exertion further than two blocks. She had no chest pain with or without exertion. She presented to an ophthalmologist on day 1 of symptoms and was diagnosed with an ocular migraine. When she continued to have episodes, she presented to a local ED for further evaluation. Head CT was negative for evidence of ischemia or hemorrhage. The patient was transferred to our institution for further evaluation. On arrival, the patient had a normal neurologic exam with no current visual field defects, which raised concern for TIA as the etiology of symptoms. A diagnostic angiogram demonstrated a 4.5 mm aneurysm located near the cerebellar artery and basilar artery junction but no vessel occlusion to suggest atherosclerotic disease as the etiology of symptoms. Subsequent echocardiogram noted a large, mobile left ventricular

thrombus in an akinetic left ventricle. Based on these results, the patient's visual symptoms were felt to be due to embolic events from the thrombus, which likely developed after a remote MI caused left ventricular infarction. Cardiac MRI showed viable myocardium, and the patient underwent cardiac catheterization and stent placement, after which she was placed on warfarin for treatment of the LV thrombus.

DISCUSSION: TIAs are defined by the AHA as brief episodes of neurological dysfunction resulting from focal cerebral ischemia and not associated with permanent cerebral infarction. TIAs are common, with approximately 200,000 to 500,000 occurring each year and an estimated incidence rate of 0.37 to 1.1 per 1000 per year. Due to the high risk of stroke after a TIA, a thorough work-up should be done to determine the etiology and treat accordingly. The AHA has developed guidelines for evaluation of patients after a TIA. Class I recommendations include head imaging, which is done both for diagnosis of TIA versus stroke, and for its prognostic value. MRI is preferred due to its higher yield. While only 13 % of CTs done after a TIA show clinically relevant ischemia, 46–81 % of MRIs show clinically relevant ischemia. Additionally, the prognostic ability of MRI is better characterized, with changes on diffusion-weighted imaging (DWI) on MRI correlating with an increased risk of stroke. In one study, the risk of stroke within 90 days of TIA was 10.8 % in patients with changes on DWI versus 4.3 % in patients without such changes. Additionally, patients should have non-invasive head and neck vessel imaging, via CT angiogram or MR angiogram performed concurrently with head imaging or as a separate study with carotid dopplers. This imaging is done to determine those patients who are most likely to benefit from carotid endarterectomy or other vessel intervention to prevent stroke. If non-invasive imaging is unclear, a cerebral angiogram should be completed, as this is the gold standard for evaluation of cerebral vasculature. Echocardiogram is a Class II recommendation in the evaluation of a TIA, as the yield is low (approximately 3 %) in the absence of history. However, an echo can be of diagnostic value when the initial evaluation has not revealed a definitive etiology, with yields improving to 61 % for a TEE. Additional Class II recommendations include EKG on presentation, and CBC, CMP, coagulation studies, and fasting lipids to be done as soon as possible to ensure that all other stroke risk factors are evaluated and treated accordingly. In summary, TIAs are common and can present with focal neurologic changes. While no evidence of infarction is noted in patients with a TIA, they are at an increased risk for stroke in the future, and therefore require a thorough work-up for the etiology and for risk stratification and management. Thoughtful utilization of the AHA guidelines allows for complete and cost-conscious care for patients who have suffered a TIA. Source: Definition and Evaluation of Transient Ischemic Attack. Stroke. 2009; 40: 2276–2293

WE SEE WITH OUR EYES, BUT WE SEE WITH OUR BRAINS AS WELL - PHANTOMS IN THE BRAIN: CHARLES BONNET HALLUCINATIONS Karan Singh; Vijairam Selvaraj. Baystate Medical Center, Springfield, MA. (*Tracking ID #1926071*)

LEARNING OBJECTIVE 1: Charles Bonnet syndrome (CBS) was first described in 1760 when he noticed his grandfather, who was blinded by cataracts, describing birds and buildings that Bonnet could not see. The prevalence of complex visual hallucinations in patients with visual impairment is estimated to be 11–15 %. They are usually transient and are often noted to occur among the educated. We describe the case of a visually impaired and psychologically intact male who reported having visual hallucinations to illustrate the importance of considering alternate explanations apart from psychological or drug induced causes when faced with these complaints.

CASE: 70 year old male with no significant medical history except for glaucoma who was functioning independently at baseline was brought in to the hospital by family as patient reported seeing “diminutive ninjas” inside his house. He was awake, alert and oriented and was able to carry a normal conversation. The patient was initially reluctant to describe his symptoms although sympathetic questioning revealed well organized and brilliantly clear, complex visual hallucinations, that were sharper than his usual vision. Prior occurrence of these symptoms had led him to realize they were not real although was frustrated by them. He was noted to have paranoid delusions that his wife may be involved with his hallucinations. MOCA testing revealed score of 21. Lab studies were normal. Eye exam revealed severe visual impairment secondary to the glaucoma. MRI of his brain revealed right occipital encephalomalacia that was related to an old infarct. Psychiatry was consulted and a diagnosis of Charles Bonnet syndrome was made although it was noted that this fixed delusion is fairly atypical.

DISCUSSION: The prevalence of CBS is grossly underestimated to be between 1.84 and 3.5 % in the geriatric population. Even though patients may not voluntarily disclose visual hallucinations, they tend to respond to leading

questions about the same. The proposed hypothesis is that in visually impaired individuals, the visual cortex compensates with abnormally increased activity and conjures up hallucinations from random firing of nerve cells. Although it is a diagnosis of exclusion, the syndrome is often under-diagnosed in clinical practice due to patients' reluctance to admit to hallucinations for fear of being labeled mentally unstable in addition to physicians' lack of awareness of the diagnosis. Physicians need to screen older adults with visual impairment for this syndrome and also be able to provide high quality education as reassurance and explanation can have a powerful therapeutic effect. Improving the visual function and addressing social isolation are also helpful in improving quality of life.

WEIGHT LOSS AND IDIOPATHIC VENTRICULAR TACHYCARDIA: A "GRAVE" SITUATION Claire Larson; Ryan Laponis. UCSF, San Francisco, CA. (Tracking ID #1920287)

LEARNING OBJECTIVE 1: Review the common causes of ventricular tachycardia
LEARNING OBJECTIVE 2: Recognize hyperthyroidism as a rare but important cause of "idiopathic" ventricular tachycardia

CASE: A 53 year old man with a history of hypertension and obesity presented with a 3 week history of fatigue and dyspnea on exertion. He reported a week-long flu like illness prior to symptom onset, and since then had decreased exercise tolerance, shortness of breath, palpitations and diaphoresis. He denied chest pain. Review of systems was positive for an 80 lb weight loss over the past 8 months. He reported a family history of hypertension, myocardial infarction, stroke, thyroid disease, and no sudden cardiac death. Exam was remarkable for a heart rate of 92. Chemistries, complete blood count, and chest x-ray were unremarkable. He underwent a stress echocardiogram which showed 1 mm upsloping ST changes in V5/V6, an apical wall motion abnormality, and multiple episodes of monomorphic non-sustained ventricular tachycardia (NSVT). He underwent coronary angiography, which showed no angiographically significant disease. He was discharged on metoprolol and verapamil, with a diagnosis of idiopathic VT. At a Cardiology appointment 10 days later, labs from his initial visit revealed an undetectable TSH and elevated free T4. He was referred urgently to Endocrinology, and at his visit there was noted to have lid lag, proptosis, thyromegaly and tremors. Laboratory evaluation and ultrasound confirmed a diagnosis of Graves' Disease. He was started on methimazole and continued on the beta blocker. Over the next 2 months, his symptoms of palpitations and dyspnea on exertion resolved. Ziopatch monitoring showed no recurrent ventricular arrhythmia, a repeat stress test revealed no arrhythmias, and he had gained 20 lb.

DISCUSSION: Most NSVT is due to either structural heart disease (most commonly due to coronary artery disease or a cardiomyopathy), or abnormal cardiac ion channels/structural proteins. Ten percent of cases are idiopathic. For patients with idiopathic monomorphic VT, the ECG between episodes, stress test, and coronary angiography should be normal. The most common form of idiopathic VT, Right Ventricular Outflow Tract VT, accounts for 70 % of all cases, and is caused by catecholamine-mediated delayed afterdepolarizations, triggered by exercise or stress. Cardiovascular symptoms in hyperthyroid states are common. T3 is transported into the cardiac myocyte, and produces findings similar to those of beta adrenergic stimulation. Clinical findings may include increased: heart rate, pulmonary artery pressure, cardiac output, ejection fracture, and myocardial oxygen consumption; and decreased: SVR and diastolic blood pressure. Sinus tachycardia is the most common rhythm abnormality in hyperthyroidism, while arrhythmias are primarily supraventricular, with atrial fibrillation occurring in 5 to 15 % of patients. Ventricular arrhythmias due to hyperthyroidism are extremely rare, particularly in the absence of underlying cardiac disease. Review of the literature reveals at least seven cases of thyrotoxicosis induced VT, with three cases in the setting of underlying CAD. In all of the patients, the ventricular arrhythmias resolved with a euthyroid state. This case highlights the initial work-up and management of ventricular tachycardia, and underscores the many cardiovascular effects of Graves' disease, including the rare side effect of ventricular arrhythmia.

WEIL HE WAS RENOVATING Poppy Markwell; Rachel Sandler; Patricia Harlan; Jeff Percak. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1926980)

LEARNING OBJECTIVE 1: Demonstrate the risk of leptospirosis during demolition work

LEARNING OBJECTIVE 2: Recognize the clinical presentation, diagnosis and treatment of leptospirosis

CASE: A 61-year-old man with no past medical history presented with 4 days of bilateral lower extremity muscle pain and subjective fevers. He also reported decreased urine output. Over the preceding weeks, he reported doing strenuous work, including demolition and renovation of a blighted New Orleans apartment. He denied recent illness, sick contacts, animal contact, or travel in the last 6 months. On physical exam, patient was febrile and leg muscles were tender to palpation bilaterally. Initial tests suggested rhabdomyolysis with CK >8000 and creatinine elevated at 4.9. Thrombocytopenia and mild transaminitis were noted. Profound hyperbilirubinemia developed during his hospital course. Renal failure ultimately required dialysis. Broad-spectrum antibiotics were given initially and changed to ceftriaxone when leptospirosis was considered. The patient fully recovered renal and liver function prior to discharge. Serologic testing ultimately confirmed leptospirosis.

DISCUSSION: Leptospirosis is a globally encountered zoonotic infection caused by the spirochete *Leptospira interrogans*, commonly through exposure to mucous membranes, conjunctiva, or breaks in the skin with infected animal urine. While common in tropical areas, the disease is re-emerging in the developed world. The occupational risk of veterinarians, miners, sewer workers and others who may contact animal urine has long been established. Demolition has been suggested as a risk factor, presumably due to exposure to materials contaminated with rodent urine. The disease classically presents as a biphasic illness: an acute phase with leptospires in the blood for about a week and an immune phase with antibody and inflammatory response. Symptoms range from self-limiting febrile illness to acute kidney injury to classic Weil's disease with jaundice, renal failure, and hemorrhage. The mortality of Weil's Disease is 10 %. Pulmonary complications and mild rhabdomyolysis are also common features. The gold standard to diagnose leptospirosis is the microscopic agglutination test. Serologic testing, including rapid tests, is also useful as culture of *Leptospira* is difficult. Penicillin, doxycycline, and cephalosporins are all used to treat leptospirosis. However, the benefit of antibiotics in acute leptospirosis infection is debated. Corticosteroids have been used to limit the damage from host immune response. Supportive care is the mainstay of treatment of severe cases. This case reminds the internist that leptospirosis can be a disease of the tropics but should be considered in cases of febrile illness in persons who have risks of exposure as may be encountered during demolition and renovation.

WHAT IS POTENTIALLY CONCEALED IN UNCONSCIOUS PATIENT WITHOUT DEFINITE ORIGIN Kanoko Fukaya; Chiaki Murase; Munehisa Atsumi; Mitsunori Iwase. TOYOTA Memorial Hospital, Toyota, Japan. (Tracking ID #1928587)

LEARNING OBJECTIVE 1: Recognize that severe sepsis can be an important cause of unconsciousness.

LEARNING OBJECTIVE 2: Remind Group A streptococcus as responsible bacteria in the rapidly progressive cellulitis.

CASE: An 87-year-old woman came to our emergency department with a history of unconsciousness. Three hours before admission, her family found her unconscious at home. She became conscious rapidly when her family called. She had no prodromal symptoms such as chest pain, headache, cold sweats, and nausea. She had atrial fibrillation without treatment and chronic heart failure on medication. She had noticed pitting edema in both legs for recent several years, but she had neither tenderness nor laterality. She also had a past history of cerebral infarction with no sequelae about a decade ago, and gastric ulcer 7 years ago. Her current medications included aspirin, azosemide, and omeprazole. On examination in the emergency department, she was alert and oriented. The body temperature was 37.2 °C, the blood pressure of 80/56 mmHg, the pulse of 51 beats per minute with irregularity, the respiratory rate of 16 breaths per minute, and the oxygen saturation 98 % while breathing ambient air. The conjunctivas were neither anemic nor icteric. The respiratory sound was clear in both lungs, and no murmur was detected. The abdomen was soft and flat without any tenderness. Neurological findings were unremarkable. EKG showed atrial fibrillation without ST-segment deviations. Though the serum troponin-I level was minimally elevated (0.28 ng/mL) at first, no additional change was detected with follow exam after 4 h. No fresh infarcted regions were found in the plain CT scan and MRI of the brain. The cause of unconsciousness wasn't revealed. We examined her again from head to toe, removing her socks. Then, we found redness, swelling, tenderness, and warmth in her left lower extremity, especially foot. There was no trauma but tinea lesions were seen at her toe. The laboratory data revealed that white-cell-count increased 20,300/µL, C-reactive protein 1.7 mg/dL, and D-dimer 11.7 µg/mL. Hemoglobin and Electrolytes, AST, CK and lactic acid were in normal range. Adding the enhanced CT image, both deep vein thrombosis and pulmonary embolism was denied. Then, cefazolin was started for the treatment of cellulitis. After admission, her blood pressure decreased to 75/48 mmHg and the pulse was 76 beats per minute. Furthermore, the redness area of the left leg lesion rapidly progressed from the foot to

the knee in several hours. She didn't have the episode such as water exposure or cat bite. We decided to add vancomycin and clindamycin. On the following day, Group A beta-hemolytic streptococcus was determined from the two sets of blood cultures on admission, then we changed the antibiotics to ampicillin and clindamycin. The treatment of antibiotics lasted for 2 weeks, and cellulitis was improved without progression to necrotizing fasciitis. Fortunately, she could go home on foot on day 20.

DISCUSSION: The chief complaint of this case was unconsciousness and its major differential diagnoses include cardiac diseases, hemorrhage, pulmonary embolism, and neurologic disorders. As for this case, these common underlying diseases were ruled out for the first step in the emergency department. It is said that when we see patients under the unexplainable conditions like consciousness disturbance, hypotension or something like that, we must not miss the signs of early sepsis. Finally we found cellulitis on her left leg by scrutinized physical examinations from head to toe. We did learn that the unconsciousness of unknown origin may be due to early sepsis. Additionally, as for the cellulitis of this case, not only did her skin findings get worse rapidly, but she became also hypotensive. Rapidly progressive erythema with signs of systemic toxicity should be considered of severe infection caused by group A beta-hemolytic streptococcus. Group A streptococcus (GAS), also called "flesh-eating bacteria", causes a wide range of infections and severe complications. Importantly, it may induce severe invasive infections such as necrotizing fasciitis and streptococcal toxic shock syndrome. One study shows that the overall case fatality rate of GAS infection was 11 % but that was much higher in patients with toxic shock syndrome (55 %) and necrotizing fasciitis (58 %). Additionally, amputation was performed in 22 % patients with necrotizing fasciitis. In this valuable case, proper antibiotic therapy was performed and finally we could save the patient's life and her left leg. Therefore, we should start antibiotics promptly under critical condition such as "flesh-eating bacteria".

WHAT IS THIS RASH OVER THE JOINTS? Ryan Morton^{1,2}; Muhammad Usman²; Lucero C. Chueca Villa^{2,1}. ¹Wayne State University School of Medicine, Detroit, MI; ²Henry Ford Hospital, Detroit, MI. (*Tracking ID #1937537*)

LEARNING OBJECTIVE 1: Recognize the clinical characteristics of Löfgren's syndrome

LEARNING OBJECTIVE 2: Expand the differential diagnosis of skin rash and arthralgias

CASE: This is a 31 year old Maltese male with a past medical history of type 2 diabetes mellitus presenting to his PCP with a 1 week history of left wrist swelling and erythema after a hunting trip in northern Michigan in November. He was prescribed Bactrim for potential cellulitis. Five days later he returned with worsening symptoms. More joints were involved as both elbows, ankles, and his left knee were also swollen with a blanching, erythematous cutaneous rash distributed only over the joints. He reported subjective fevers throughout the course of the disease but had no recorded temperature. Lyme titers were drawn, arthrocentesis was performed in the left ankle, and doxycycline was prescribed with follow up in 4 days for potential Lyme disease. At follow up, he was tachycardic and had a leukocytosis of 18,000 cells/mL so he was admitted to Henry Ford Hospital. He denied any target shaped lesions, sore throat, bug bites, sexual contact, history of STD's, contact with carcasses, family history of autoimmune disease, chest pain, shortness of breath, abdominal pain, dysuria, or diarrhea. A salmon colored macular rash on his chest was also observed on admission, which had been unnoticed by the patient. Lab tests showed slight elevations in AST and ALT and a marked drop in albumin of 2.2 g/dL. He had a slight microcytic anemia with low serum iron and significantly elevated ferritin at 900 ng/mL. Blood and synovial cultures were negative for growth and Lyme titers were negative. Other infectious etiologies were ruled out as HIV, hepatitis C, and syphilis showed negative results. Parvovirus was positive for IgG but negative for IgM. An ANA was slightly positive with titer levels of 1:160 and a speckled pattern of immunofluorescence but double stranded DNA tests were negative. Other autoimmune etiological tests were negative including RF, ENA, ANCA, and celiac panel tests. A chest x-ray was performed that showed right sided hilar adenopathy suspicious for sarcoidosis, confirmed by a CT scan of the chest. Elevated ACE levels of 64 U/L, lysozyme levels of 23 ug/mL, and a biopsy showing septal panniculitis consistent with erythema nodosum confirmed the diagnosis of Löfgren's syndrome. The patient was diagnosed with sarcoidosis, discharged, and is currently on a treatment regimen of prednisone and methotrexate with significant improvement of his symptoms.

DISCUSSION: Löfgren's syndrome is an acute type of sarcoidosis that is defined by the triad of migratory arthralgias, bilateral hilar lymphadenopathy, and erythema nodosum. It is most frequently found in women, and is more common in Scandinavian and Irish populations. Erythema nodosum presents as erythematous tender nodules. Lesions can appear on any extremity or on the trunk, but are typically present on the pretibial surfaces of both legs. These are deep, evolving lesions which usually are difficult to visualize initially. Lesions progress to red or violet cutaneous

lesions and spontaneously resolve over 2 to 8 weeks. Non specific symptoms such as fever, malaise and polyarthralgias frequently accompany erythema nodosum. The etiology is unknown but a Type IV delayed hypersensitivity reaction is the most likely pathogenesis suspected at this time. As other symptoms in addition to erythema nodosum spontaneously remit as well, the prognosis associated with Löfgren's syndrome is quite good. Males presenting with sarcoidosis generally do not have erythema nodosum, rather they typically present with bilateral ankle arthritis. Our patient was atypical in a number of ways, in that no nodules were palpated, his lesions were non-tender and only distributed over the joints, and his sex and ethnicity make sarcoidosis less likely. This atypical presentation of sarcoidosis and erythema nodosum should be considered in the differential diagnosis of any patient presenting with polyarthralgias or unexplained erythematous cutaneous lesions. This would avoid the unnecessary testing seen in our patient, facilitating appropriate diagnosis and prompt treatment.

WHEN DOCTORS THINK THEY KNOW Dima Dandachi; Venu Pararath Gopalakrishnan. Saint Francis Hospital, Evanston, IL. (*Tracking ID #1925291*)

LEARNING OBJECTIVE 1: Suspect Septic Pulmonary Emboli in a patient with multiple bilateral peripheral pulmonary nodules and fever with or without obvious predisposing factors.

LEARNING OBJECTIVE 2: Treat Septic Pulmonary Emboli early with prompt antimicrobial therapy to achieve a successful outcome.

CASE: A 54 years old, previously healthy male patient, presented to our hospital with acute onset left sided severe chest pain that progressed in intensity over 1 week. The pain was sharp in character, worsened with inspiration, and not relieved with 10 tablets of ibuprofen a day. He complained of mild dry cough and occasional chills but didn't have any documented fever, sputum, hemoptysis or shortness of breath. Review of system was positive for bright blood per rectum occasional for the last year that was attributed to hemorrhoids. Denied any unintentional weight loss, nausea or vomiting. He had a root canal procedure done 3 weeks ago. His is a smoker 30 pack year, drinks alcohol occasionally, denied any IV drug abuse, works as a cab driver. In the Emergency Department patient was in severe distress because of pain. Patient was afebrile and hemodynamically stable male with Clinical examination revealed normal heart and respiratory findings. Abdominal exam was positive for mild epigastric tenderness, fecal occult blood test was positive. Hemogram revealed WBC of 12.8 k/mm cu, hemoglobin 11.9 g/dL and MCV 89 fl. CT Chest with contrast done was negative for pulmonary embolism, but showed multiple bilateral pulmonary nodules suspicious for malignancy. Left upper lobe showed subpleural 2.4×1.5 cm rounded opacity, emphysematous changes, left hilar lymphadenopathy and moderate size left sided effusion. CT abdomen and pelvis showed folds in the stomach are thickened, otherwise unremarkable. The patient was informed about the most likely possibility of a gastrointestinal malignancy with lung metastasis or primary lung malignancy. Next day, EGD done was negative. Colonoscopy showed non-bleeding internal hemorrhoids, the rest of the exam was normal. He underwent percutaneous CT guided lung biopsy. Pathology report surprisingly showed distended alveoli filled with polymorphonuclear leukocytes mixed with fibrin, no evidence of malignancy, findings consistent with septic emboli. Special stains for organisms were negative. Blood cultures were negative, Trans-esophageal echocardiograph was normal. Mandibular film done was negative for dental abscess. HIV serology, Quantiferon gold, Beta-d glucan, Aspergillus, mycobacterial culture of sputum and pleural fluid were negative. During hospital stay patient developed fever when antipyretics were stopped and his WBC count increased. Left sided thoracocentesis was done and pleural fluid analysis revealed exudative fluid by light's criteria. Both gram stain and culture of pleural fluid were negative. Patient started empirically on Ceftriaxone and Vancomycin. Patient improved significantly. Antibiotics were continued for 14 days. He was discharged home in a stable condition.

DISCUSSION: Septic pulmonary emboli (SPE) is a serious and uncommon condition that poses a diagnostic challenge. Patients with septic pulmonary emboli who are diagnosed early and treated with broad-spectrum antibiotics have a better prognosis than patients with a delayed diagnosis. Establishing the diagnosis of septic pulmonary emboli is not always straightforward, as the radiographic findings may be non-specific. Blood cultures may be negative initially and there may not be a detectable heart murmur. Septic pulmonary emboli travel to the lungs from numerous sources, including infected heart valves, peripheral sites of septic thrombophlebitis, and infected indwelling venous catheters. Other patients at risk are those with odontogenic infections. In patients with a history of intravenous drug use, the most common source of septic pulmonary emboli is an infected tricuspid valve. An echocardiogram can be obtained to evaluate for the presence of tricuspid valve vegetations. However, echocardiography may be limited technically and very small vegetations (less than 3 to 4 mm) may not be detected. Usual presenting symptoms are often non specific. Similarly, chest radiography is not helpful to establish a diagnosis. CT is more useful, usually shows multiple nodular opacities peripherally located. SPE can be suspected by the presence of potential source of underlying infection, febrile illness and multiple pulmonary nodules. Most common pathogen involved is Staph Aureus. We report a case of septic pulmonary emboli that was misdiagnosed as malignancy. SPE can be fatal therefore early diagnosis and appropriate antibiotic therapy are important for the control of the infection.

WHEN EYES DROOP AND THINGS GET BLURRY - THINK BOTULISM

Robert H. Cooper¹; Roger D. Smalligan²; Casie Stoughton⁴; J. M. Richardson⁴; Deree Duke⁴; Aimee L. Geissler³; Agam K. Rao³; Sarah D. Bennett³; Reid Harvey³; Sara Syeda¹; Beverly Nixon-Lewis¹. ¹Texas Tech University HSC, Amarillo, TX; ²Texas Tech University HSC, Amarillo, TX; ³Centers for Disease Control and Prevention, Atlanta, GA; ⁴Potter-Randall Bi-County, Amarillo, TX. (Tracking ID #1934880)

LEARNING OBJECTIVE 1: Recognize presenting symptoms of botulism to treat the patient and stop an outbreak.

LEARNING OBJECTIVE 2: Differentiate botulism from other neuromuscular disorders.

CASE: A previously healthy 32-year-old Iraqi man presented with blurry vision and difficulty speaking for 3 days. He denied fever, chills, headache, neck stiffness, nausea, vomiting, diarrhea, constipation, chest pain and shortness of breath. He had no recent travel, denied smoking, alcohol and drug use. There was no FH of neurologic disorders. On physical exam he was alert, oriented and had normal vital signs. Heart, lung and abdominal exams were normal. Neuro exam showed ptosis, disconjugate gaze and reactive pupils. He had dysarthria, bilateral facial droop and neck weakness, and no gag reflex. No other deficits in strength were observed and DTR's were normal. Initial testing included CBC, CMP, UDS, LP and MRI of the head and neck, all of which were negative or nonspecific. A Tensilon test was negative and additional tests for heavy metals, acetylcholine receptor antibodies and polio were negative. The patient identified two ill contacts who presented with similar signs and symptoms within the previous month, both were diagnosed with atypical myasthenia gravis due to a slightly positive Tensilon test and neither responded to pyridostigmine. One of these contacts had been discharged a few weeks earlier and the other was admitted days earlier and required mechanical ventilation. This similar presentation of three friends within 1 month raised the suspicion of botulism. The local health department and the CDC were notified immediately. After careful review of the case histories, signs and symptoms, botulinum antitoxin was released and administered within 8 h to the two patients who had ongoing progression of symptoms. The apartment shared by all three case patients was searched and potentially contaminated foods which were tested. A fourth case (acquaintance of the 3) was identified at a separate hospital. After many hours of interviews, a common food source was found that the four case patients had eaten at two different apartments on at least three separate occasions. The shared food product was a common Middle Eastern dish known as turshi and was prepared by the case patient with the earliest symptom onset. The turshi was made with fresh vegetables that were fermented at room temperature for weeks. No turshi was available for definitive testing; however, fermented vegetables are known to be associated with botulism outbreaks. Serum and stool samples from the case patients were negative for botulism by mouse bioassay. EMG/NCV testing was conducted on two of the case patients and results were inconclusive. In addition to the botulinum antitoxin administered, supportive care was provided to each patient, three of whom showed slow but consistent improvement and were discharged home. All were given education on proper food preparation techniques. The intubated patient required tracheostomy and longer term mechanical ventilation, but continues to improve slowly.

DISCUSSION: Although on average around 17 cases of adult botulism, caused by toxin production of Clostridium botulinum, are confirmed annually in the USA, myasthenia gravis and Miller-Fisher variant of Guillain-Barre syndrome can have similar presentations to botulism leading to botulism cases being misdiagnosed. Much of the confusion is due to the rarity and the varied way in which botulism can present, including combinations of ptosis, diplopia, slurred speech, dysphagia, dysarthria, muscle weakness and respiratory depression. Classically, it presents with descending paralysis with cranial nerve deficits. Work-up can be misleading as well since false-positive Tensilon tests can occur as in 2 of our cases. EMG/NCV studies are difficult to interpret unless the operator has experience with botulism. Although honey is often associated with botulism, it is only relevant in infant botulism cases. Home canned foods are the most common source of foodborne botulism, while black tar heroin is the most common cause of wound botulism. If botulism is diagnosed promptly, antitoxin can be administered to neutralize circulating toxin, halt symptom progression and shorten disease course; however, existing nerve damage is not reversed. Supportive care is required for days to months to allow for nerve regeneration. CDC has an on-call botulism team available 24/7 to discuss suspected cases and release antitoxin immediately when a single case or outbreak occurs. In conclusion, it is imperative for physicians to include botulism in the differential diagnosis of patients with ptosis, ocular and bulbar symptoms, facial paralysis and dysphagia in addition to descending flaccid paralysis as prompt administration of antitoxin can significantly improve outcomes. Early involvement of the health department and CDC is also needed to identify the food source in the event of a botulism outbreak and thus prevent additional cases of intoxication.

WHEN OCCAM'S RAZOR FAILS: LINEZOLID INDUCED LACTIC ACIDOSIS IN A PATIENT WITH SEVERE AORTIC ATHEROSCLEROTIC DISEASE

Karan Singh; Sunitha Alluri. Baystate Medical Center, Springfield, MA. (Tracking ID #1926067)

LEARNING OBJECTIVE 1: Linezolid induced lactic acidosis was first reported in 2003, and till date there are only few case reports about the same. Linezolid is often used for prolonged duration and thus it is important to keep this side effect in mind. **CASE:** 65 yo M with a complicated PMH which included uncontrolled Diabetes, with numerous prior complicated diabetic infections on Linezolid since the past 6 weeks. He had severe PVD, CKD, CAD s/p CABG along with severe diabetic gastroparesis. He presented with vague complaints of nausea, vomiting and lethargy for 3 days. He clearly denied any abdominal pain. He denied any constipation or diarrhea. He resided in a nursing home and review of their records did not reveal any episodes of hypotension. He was in NSR and his abdomen was soft and non-tender. He had a wound vacuum on, and the wound itself was healthy. His labs revealed a lactate of 6, with an AG of 20 and bicarbonate of 21. He was also pancytopenic and his platelet and WBC counts were normal 2 months back. A CAT scan was done of the abdomen which did not reveal any evidence of colitis. Considering his overall picture, it was thought to be type B Lactic acidosis secondary to Linezolid. On review of his records, there were no new medications except Linezolid. Patient's lactic acidosis and thrombocytopenia both resolved within 5 days of stopping Linezolid.

DISCUSSION: There are limited choices for oral antibiotic therapy in disease caused by resistant gram positive organisms. This is what has made Linezolid an attractive option when IV access is not feasible or when the duration of treatment is long. Linezolid is currently FDA approved for the treatment of Vancomycin resistant Enterococcus, nosocomial pneumonia caused by Staphylococcus and Streptococcus, complicated skin and skin structure infections and community acquired pneumonias. The mechanism by which this drug causes lactic acidosis has not completely been elucidated. Mitochondrial toxicity has been proposed as a causative mechanism. There have also been mortalities reported due to this adverse effect. There is no proven therapy to treat Linezolid induced Lactic Acidosis. In addition to cessation of the drug, thiamine has been used in treatment (potential benefits without harm). A review of the literature reveals that the majority of episodes occurred in older patients and those getting prolonged therapy, and resolution of lactate levels varied from 2 days to 2 weeks. This case and others described in the literature demonstrate importance of continuous monitoring of medication related adverse effects and those factors which might predict which patients are at higher risk.

WHEN SEIZURES CAUSE DROWNING - WITHOUT THE WATER

Alice Williamson; Eric Kasprowicz; Ramprasad Kandavar. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #1926987)

LEARNING OBJECTIVE 1: Identify common and uncommon causes of seizure
LEARNING OBJECTIVE 2: Understand the importance of seizure management

CASE: A 31 year old woman presented to the emergency department after having a grand-mal seizure at work. The seizure resolved prior to EMS arrival. In the emergency department, she had another grand-mal seizure that resolved with lorazepam. She also developed shortness of breath and was found to be hypoxic requiring supplemental oxygen via nasal cannula. She was admitted to medicine for further support and work-up. Of note, she had a known seizure disorder but had been unable to fill her one of prescriptions. Also, our patient had suffered from past episodes of pulmonary edema requiring intubation during episodes of seizures. On exam (when patient was no longer post-ictal), vitals were normal except respirations were 22 with oxygen saturation 85 %. She was alert and oriented, able to speak in full sentences though with a little bit of respiratory distress. She had faint bibasilar crackles on lung exam. CBC and metabolic panel were normal. Valproic acid level was less than 3. Chest x-ray revealed a cardiomedastinal silhouette that was enlarged with continued findings of volume overload including interstitial and alveolar edema, central venous congestion and mild bilateral pleural effusions (consistent with previous chest x-rays taken after she had seized).

DISCUSSION: While uncommon, we diagnosed our patient with neurogenic pulmonary edema (NPE). NPE is defined as clinical syndrome characterized by the acute onset of pulmonary edema following a significant central nervous system insult (1). Upon close review of her medical record and prior imaging, we discovered that our patient had been admitted on three separate occasions due to seizures associated with hypoxia and pulmonary edema, all of which required ICU admission and at least one requiring intubation. Previously, she had been diagnosed with aspiration pneumonitis associated with her seizure activity. While such a diagnosis is plausible, the recurrence of these episodes led our team to establish the diagnosis of neurogenic pulmonary edema. During this admission, she was treated with intravenous furosemide and supplemental oxygen via nasal cannula. This diagnosis of NPE further underscores the importance of controlling our patient's seizure disorder.

WHEN SHOULD WE CONSIDER SYSTEMIC LUPUS ERYTHEMATOSUS IN PATIENT PRESENTS WITH GUILLEAIN-BARRE SYNDROME Hamza H. Tantoush; Ahmed Abuzaid; Haitham Al Ashry. Creighton University Medical Center, Omaha, NE. (*Tracking ID #1917176*)

LEARNING OBJECTIVE 1: Lupus should be considered in patients with Guillain-Barré syndrome who do not respond to intravenous gamma globulins

CASE: A 59 years old female presented with progressive muscle weakness of arms and legs proximal more than distal, together with paresthesia in both hands and feet for one-month duration. Her medical history was remarkable for depression, hypertension, and GERD. Physical examination on admission revealed a blood pressure of 156/86-mmHg and Neurological examination showed absent deep tendon reflexes, and severe symmetrical muscle weakness lower and upper limbs proximal more than distal. Cranial nerves are all normal. Sensory examination showed diminished sensation to light touch pain, vibration and sense of position. The sensory perception was more impaired distally compared to proximally and on the trunk. Patient did not show any urinary bladder or anal sphincters problems. Laboratory revealed an increased esr, crp, normal creatinine, low serum albumin normal LDH, low Platelets, low leucocyte count Folic acid and B12 all normal. Serum and urine protein electrophoresis were negative; The cerebrospinal fluid revealed protein cellular dissociation; urine analysis revealed high urine protein of spot protein creatinine ratio increased. Brain and neck magnetic resonance imaging did not show any pathologic lesions suggesting her weakness. The electromyogram and nerve conduction velocity also indicated sensorimotor demyelinating polyneuropathy. Treatment was started with oral prednisone and intravenous immunoglobulin G for 3 days. No improvement in her muscle weakness. Because of significant proteinuria, additional investigations were performed, including autoimmune serology. These revealed a positive antinuclear antibody ANA test, anti dsDNA, negatives both C/P ANCA, and decreased C3 and slightly decrease C4 values which raised the suspicion of SLE diagnosis. A percutaneous kidney biopsy was performed, which showed membranous lupus nephritis Class V. Because of this severe form of lupus nephritis the patient was treated from day 8 with Mycophenolate along with the high doses oral prednisone. This treatment regimen was tolerated rather well.

DISCUSSION: The prevalence of SLE in patients with Guillain-Barré syndrome has been reported to be between 0.6 and 1.7 %. Diagnosis of Guillain-Barré syndrome is confirmed if the CSF, and clinical neurophysiology studies show typical abnormalities Acute inflammatory demyelinating polyneuropathy, is the most common form of Guillain-Barré syndrome in the most parts of world. Because of the combination of Guillain-Barré syndrome and lupus nephritis, it is difficult to formulate an optimal therapeutic regimen. The treatment strategy is important in early phase of acute neuropathies with pulse steroid and plasma exchange. The association of Guillain-Barré syndrome with lupus seems to have implications for both treatment and prognosis. Prednisone and immunosuppressive therapy cyclophosphamide or mycophenolate should be considered in patients with, Guillain-Barré syndrome as a feature of lupus nephritis.

WHEN SIZE BEGINS TO MATTER: ISONIAZID-INDUCED GYNECOMASTIA IN A PATIENT WITH LATENT TUBERCULOSIS Joanna Marie B. Aquino-Laban¹; Aimee L. Mandapati². ¹Summa Health System, Akron, OH; ²Summa Health System, Akron, OH. (*Tracking ID #1912687*)

LEARNING OBJECTIVE 1: Recognize the clinical features of isoniazid-induced gynecomastia in a patient with latent tuberculosis

CASE: A 65-year-old asymptomatic African-American male presented with a positive tuberculosis (TB) skin test (~22 mm) found during routine testing for hospital volunteers. He is a retired chemist and denied any recent travel, but reported possible TB exposure during his previous volunteer job in a hospital. Chest x-ray was negative. The patient was diagnosed with latent TB infection, and was started on a 9-month regimen of daily isoniazid and pyridoxine. About 7.5 months after initiation of therapy, the patient noted bilateral breast swelling and tenderness. He denied headache, blurred vision, nipple discharge, or changes in secondary sexual characteristics. Blood work showed mild elevation of estradiol, follicle stimulating hormone, and prolactin. Mammogram confirmed the presence of gynecomastia. Given the temporal association of the anti-TB drug to the occurrence of breast swelling, isoniazid was immediately discontinued. One month after withdrawal of the drug, the patient reported partial resolution of his symptoms. He continues to feel better as of this writing.

DISCUSSION: Gynecomastia is a rare but recognized side effect of isoniazid therapy with at least 14 cases reported worldwide. Proposed mechanisms include altered vitamin B6 breakdown leading to defective hepatic estrogen-androgen metabolism, increase in gonadal function after weight gain (“refeeding gynecomastia”), and inhibition of cytochrome P450 system that may impair estrogen metabolism in the liver. Better understanding of this drug association can lead to prompt recognition and appropriate management. To our knowledge, this is the first case report of this rare side effect of isoniazid in the United States, and first in latent tuberculosis worldwide.

WHEN THE MCV IS THE MVP! Alice Williamson; Arti Allam; Ramprasad Kandavar. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1926978*)

LEARNING OBJECTIVE 1: Understanding the importance of the entire CBC

LEARNING OBJECTIVE 2: Comprehending the work-up for abnormal CBC values

CASE: A 24-year old woman with sickle cell disease presented to the emergency department complaining of bilateral lower extremity pain as well as back pain and stomach pain. She stated that the pain was consistent with her sickle cell type pain began 2 days prior to presentation. Her vitals included a temperature of 37.1, pulse of 78, blood pressure of 120/80, respiratory rate of 16, and O2 saturation of 100 % on 2 L nasal cannula. She was in mild distress, complaining of diffuse pain, but alert and oriented. She had mild scleral icterus and a 2/6 systolic murmur. Her lungs were clear to auscultation bilaterally, and her abdomen was soft with diffuse right upper quadrant and epigastric tenderness to palpation. Bowel sounds were present, and her extremities were warm with no rashes or edema. Laboratory values included WBC 10.5, Hgb 7.9, PLT 477, MCV 109.1, RDW 15.7, Na 139, K 3.8, Cl 105, Bicarb 22, BUN 4, Cre 0.4, Ca 8.9, Folate level 18.4, and B12 level 163. Further Work-Up revealed an Anti-Intrinsic Factor Antibody Negative (normal), Anti-Parietal Cell Antibody 38.6 (high), and Methylmalonic Acid (MMA) 129 (within normal range based on healthy blood bank donors).

DISCUSSION: Pernicious anemia is not commonly associated with sickle cell anemia; however, B12 deficiency may be under diagnosed in black patients (1, 2). As of 2010, only four cases of these disease coexisting were documented (3). In a patient with chronic pain issues due to sickle cell disease, vitamin B12 deficiency could easily be overlooked as a contributor to a patient's pain. This case is peculiar in that her B12 was low and she had Anti-Parietal Cell Antibodies present but her MMA was within normal range—a range defined as normal based on the values of healthy blood bank donors. This may be associated with the proposed changes in metabolic pathways in patients who have cobalamin deficiency (4). Another possible explanation is a low serum transcobalamin, though this was not assessed in our patient nor would that explain the antibodies to parietal cells (3). Regardless of these contradictions and based on the risk-vs-benefit of starting Vitamin B12 replacement, we treated this patient for B12 deficiency. This case reminds clinicians to scrutinize every CBC and to question abnormalities. In this case, a patient with HbSS should have a low MCV, not a high MCV.

WHEN THE PAST CLOUDS THE PRESENT: A UNIQUE CAUSE OF ACUTE ON CHRONIC BACK PAIN Craig Mescher; Asher Tulsky. University of Pittsburgh Medical Center, Pittsburgh, PA. (*Tracking ID #1938733*)

LEARNING OBJECTIVE 1: Appreciate that bias exists in the care of patients who present with low back pain.

LEARNING OBJECTIVE 2: Recognize the importance of identifying red flags in acute back pain and their impact on pretest probability for serious disease particularly in patients on chronic opiates.

CASE: A 49 year old female with a history of fibromyalgia with chronic back pain on opiate medication and left breast atypical ductal hyperplasia initially presented to the ED with new onset right lower back pain radiating to her right groin and thigh not controlled by her usual pain regimen. A lumbar spine x-ray was negative for bony lesions and she was discharged home with pain medications. Six days later she returned to the ED now with low back pain radiating down both legs. A CBC showed WBC 17.6, hemoglobin 9.6 and platelets 42 K, normal one-year prior. She was treated with methylprednisolone, cyclobenzaprine, and Percocet for presumed sciatica and told to follow up with her PCP regarding her CBC. Two days later she again presented to the ED as her back pain was not controlled, she was admitted for further work up. A CBC now revealed a WBC 18.5 with a differential of 23.1 % neutrophils, 6.5 % lymphocytes, 38.9 % blasts, 13 % myelocytes, 10.2 % metamyelocytes, hemoglobin 8.3 and platelets 23 K. She was to be transferred to the cancer institute for further care when shortly before transfer she developed severe back pain with numbness of her feet and the inability to move her legs. Neurological exam now showed markedly diminished strength of both proximal and distal lower extremity muscle groups in addition to loss of deep tendon reflexes and rectal tone. MRI of her lumbar spine demonstrated a 5.2×1.4 cm mass within the dorsal epidural space from L2-L4 with extension into bilateral L3 neural foramina. She underwent emergent neurosurgical resection of the mass, which on pathology was diagnosed as a myeloid sarcoma. Peripheral cytogenetics were positive for acute myelogenous leukemia with a 8;21 translocation. She received induction chemotherapy with idarubicin plus cytarabine followed by spinal radiation and HIDAC consolidation therapy.

DISCUSSION: Low back pain is a common presenting complaint among patients with a reported one-year prevalence as high as 73 %. It is often of a benign etiology and treated conservatively. Prejudices exist that affect the management of low back pain. African American race, low socioeconomic status, and patients with any history of substance abuse receive more conservative measures. Imaging studies are pursued early in patients with red flag symptoms that suggest a serious spinal cause. These include weight loss, history of cancer, age over 50, urinary retention, fever, saddle anesthesia, intravenous drug use, and progressive neurological symptoms. When red flag symptoms are absent, a serious spinal cause is almost always ruled out, but in as many as 80 % of people one red flag sign is present while the prevalence of serious cause is 0.9 % suggesting higher sensitivity than specificity. Additionally, failure of conservative measures adds to the sensitivity of detecting a malignant process. Cauda Equina syndrome is as such a rare but serious entity and clinical judgment is prudent. Myeloid sarcomas, or chloromas, are tumor masses composed of immature myeloid cells found outside of the bone marrow. These are rare presentations of hematologic malignancies that can occur with or independent of a bone marrow process. Although there is no ideal treatment, the primary treatment method is chemotherapy and radiation of the underlying malignant process. Surgical removal of the sarcoma is not needed unless required emergently. Cytogenetically, the 8;21 translocation had been repeatedly associated with myeloid sarcomas.

WHEN THINGS DON'T FIT ... THINK ACROMEGALY A CASE SERIES

Patrick Quinlan; Mrunalini Deshmukh; Arti Patel. Reading Hospital, Wyomissing, PA. (*Tracking ID #1934133*)

LEARNING OBJECTIVE 1: Recognize the various presentations of Acromegaly in different settings.

CASE: A 59 year old male with a PMH of resistant HTN, OSA, and DM II presented to Rheumatology for evaluation of persistent right hip pain for 1 year, in addition to the increasing size of his hands, feet, and head circumference. Rings and shoes that he had worn previously no longer fit. Considering the patient's advanced degenerative arthritis, deep voice, enlarged tongue, enlarged mandible and general physical habitus, the diagnosis of Acromegaly was suspected. The patient was found to have elevated IGF (629 ng/ml) and an MRI of the brain revealed an 11 mm mass. The patient was referred to neurosurgery for transphenoidal Resection. A 34 year old female with a PMH of PCOS, depression, and OA presented to her general internist with the chief complaint of a change in her physical appearance in comparison to her twin sister. She was found to have an elevated growth hormone level of 5.01 ng/ml. She was subsequently referred to endocrinology; at the time of presentation she also had galactorrhea. Her prolactin level was 32.7 ng/ml. She was also noted to have an 11 mm mass on MRI of the brain. A 34 year old, Hispanic female with a PMH of carpal tunnel syndrome, presented to the emergency room complaining of a severe headache for 1 day. She had intermittent mild headaches in the past. CT scan of the brain was done which revealed a sellar-based invasive mass. MRI of the brain confirmed an infiltrating mass lesion of the sella turcica which measured 37×28 mm with partial encasement of the cavernous carotid arteries bilaterally. The patient had noticed a change in her facial features over the last 5 years with enlargement of her nose, lips and tongue. Ring and shoe sizes were increased. She was found to have an elevated growth hormone level of 2103 mg/dL and a fasting insulin-like growth factor of 1022 mg/dl.

DISCUSSION: Acromegaly is a condition that results when the anterior pituitary gland produces excess growth hormone (GH) after epiphyseal plate closure at puberty. Classic features include frontal bossing, increased teeth spacing, arthritis, and enlargement of the tongue, lips, nose, hands and feet. It takes several years to manifest these classic features. The first patient in this series exhibited these typical features. The second patient in the series had galactorrhea and a change in facial and physical appearance in comparison to her twin sister as presenting features. This is not surprising as 20–30 % of patients with GH secreting pituitary adenomas also co-secrete prolactin. Although the classic feature of a sellar mass is bitemporal hemianopia, severe headache can be a presenting feature of a pituitary mass and Acromegaly. All three patients were asked to bring their old pictures to see the change over the years. In all three patients diagnosis was confirmed by glucose suppression test.

WHERE ARE THE BLISTERS? A CASE OF BULLOUS PEMPHIGOID WITHOUT BULLAE Victoria T. Liu; Karen Y. Cheng; Pearl Yu. University of California, San Diego, La Jolla, CA. (*Tracking ID #1940162*)

LEARNING OBJECTIVE 1: Recognize drug-induced, urticarial bullous pemphigoid when bullae are not present.

LEARNING OBJECTIVE 2: Diagnose bullous pemphigoid when direct immunofluorescence and serologies are negative.

CASE: An 80-year-old male presented with a 2 week history of rash, distributed mainly on the abdomen and flanks. The rash is associated with pruritus, but no pain or burning. He denied recent changes to medications, topical exposures, hospitalizations, antibiotic use, and increased sun exposure. Medical history was significant for hypertension on lisinopril, and chronic obstructive pulmonary disease (COPD) on low dose prednisone (6 mg daily). Physical exam revealed non-scaly urticarial pink plaques confined to the abdomen and flanks. A punch biopsy showed superficial perivascular inflammation with prominent eosinophils. A second biopsy was obtained for direct immunofluorescence (DIF), which was negative. In the meantime, the patient improved symptomatically with topical clobetasol. Patient's serum was sent for indirect immunofluorescence (IIF), and enzyme-linked immunosorbent assay (ELISA) for antibodies against bullous pemphigoid (BP) antigen 180 and 230. IIF showed positive IgG staining on monkey esophagus substrate at 1:5120 (high) and on human substrate 1:640 (high). Salt split skin assay showed staining on the epidermal roof, consistent with BP. The serum was negative for BP180, BP230 and IgA. Lisinopril was discontinued and replaced with losartan. One month later, patient reported great improvement with resolution of pruritus, and physical exam showed resolving plaques.

DISCUSSION: When assessing rashes in the elderly, BP should be included in the differential. The median age at presentation for BP is 80 years, the same age as our patient. The most commonly involved sites are the trunk, extremity flexures, axillae, and inguinal folds, but up to 30 % of cases remain localized to one area. Though of course the classic presentation of BP is tense bullae, other variants include urticarial, eczematous, vesicular, verruciform, and even pruritis without any visible lesions. If there is urticaria, it can be during the prodromal phase preceding the development of bullae, or an urticaria-only variant of BP, as was the case with our patient. Urticarial BP can be distinguished from true urticaria because the lesions of BP are not transient. Classically, BP is considered an intrinsic autoimmune disorder, but exposure to drugs or infections can also precipitate it, likely due to cross-reactivity of antibodies with the basement membrane. Our patient appeared to have a drug-induced variant of BP, given that his rash resolved with the discontinuation of lisinopril. The absence of elevated ELISA for the most common antigens for BP (BP180 and BP230) can support the diagnosis of drug-induced BP, but it is also possible that our patient had a less common protein target (eg. BP200). Interestingly, our patient's clinical presentation and lab results could both have been muted by chronic prednisone for his COPD. Another important lesson from this case is that BP can be diagnosed even in the absence of positive DIF or serological findings. In a patient with suspected BP, the standard approach is to begin with a punch biopsy of the lesion for H&E staining and of the perilesion for DIF. Though DIF is the reference standard, diagnosis can be made with serum specimens for IIF and ELISA to detect circulating basement membrane antibodies. This case illustrates a non-classical variant of BP that can obscure the diagnosis.

WITH A SPONGY HEART Cindy Wang; Matthew Shaines; Daniel Spevack. Montefiore Medical Center, Bronx, NY. (*Tracking ID #1939728*)

LEARNING OBJECTIVE 1: To learn the classification of cardiomyopathies

LEARNING OBJECTIVE 2: To recognize, diagnose, and treat non-compaction cardiomyopathy

CASE: 65-year old male with no significant PMH complained of shortness of breath for 2–3 days. In the same time his exercise tolerance had acutely decreased to a few steps. His father had a myocardial infarction at age 58. On exam, there was a 3/6 systolic murmur, crackles bilaterally at the bases, and 1+ pitting edema bilaterally. Lab results showed troponin peaking at 0.03 ng/mL and a pro-BNP 3653 pg/mL. Electrocardiogram showed atrial flutter and left ventricular hypertrophy. Echocardiogram revealed severe diffuse hypokinesis and an ejection fraction of 30 %. Cardiac catheterization demonstrated normal coronary arteries. MRI showed extensive spongy trabeculation in the LV apex consistent with non-compaction cardiomyopathy. Extensive delayed enhancement (indicating scarring) of the mid-myocardial layer was present in the septum, apex, and lateral walls. The patient was started on medical management and an ICD was implanted.

DISCUSSION: Cardiomyopathies (CMs) can be classified into two groups—primary and secondary. Primary CMs are limited to the heart, while secondary CMs are cardiac manifestations caused by other systemic diseases. The secondary or “extrinsic” CMs are due to metabolic, endocrine, neuromuscular, inflammatory, or nutritional causes. Ischemic CM is used to identify coronary artery disease as the etiology of heart failure, and is the most common cause of heart failure in developed countries. The primary CMs are fewer in number and are separated into three types—genetic, mixed, and acquired. Acquired CMs include inflammatory (myocar-

ditis), stress-provoked (tako-tsubo), tachycardia-induced, and peripartum. Mixed CMs include dilated and restrictive, which are combinations of genetic and nongenetic. Genetic CMs include hypertrophic, glycogen storage disease, conduction defects, mitochondrial, ion channels disorders (Brugada), and left ventricular non-compaction. Non-compaction cardiomyopathy (NCCM) is a congenital disease of the heart muscle caused by a disruption in the process of myocardial compaction during embryogenesis. The resulting myocardium becomes "spongy" in appearance, with trabecular myocardial fibers forming sinusoidal recesses that communicate with the left ventricular cavity. It is both sporadic and familial, with at least nine specific gene mutations identified. Some examples of reported mutations are troponin T/I, tropomyosin, myosin heavy chain, and myosin binding protein. It manifests clinically as congestive heart failure, arrhythmia, and arterial thromboembolic events. The prevalence is uncertain but has been found in 0.014–0.26 % of all adults referred to echocardiography. The average age of diagnosis is typically in the 40s, but has been diagnosed as early as 11 months and as late as 94. The differential includes other CMs (dilated, restrictive, hypertrophic), myocarditis, pericarditis, aberrant chordae tendineae, left ventricular thrombi, and intramyocardial hematomas/abscesses. Echocardiography is the test of choice for diagnosis, but cardiac MRI is also utilized. Treatment involves heart failure and arrhythmia management, following the same guidelines as other patients. Long-term anticoagulation has been proposed due to the higher incidence of embolic events, but there are no concrete guidelines. Patients should be screened for other musculoskeletal disease. Due to its hereditary nature, first-degree relatives should consider echocardiographic screening or genetic testing.

WOMAN, INTERRUPTED: AN UNUSUAL CAUSE OF PSYCHOSIS Sara Attalla; Deborah Hemel. Montefiore Medical Center, Bronx, NY. (*Tracking ID #1939021*)

LEARNING OBJECTIVE 1: Recognize hallmark neuropsychiatric symptoms of anti-NMDA receptor encephalitis

LEARNING OBJECTIVE 2: Initiate treatment as early as possible to optimize chances for recovery

CASE: A 31 year-old female with no past medical or psychiatric history presented with acute behavior changes. According to her family, the patient was in her fully functional state of health until 1 week prior when they noted changes in mood; she cried frequently, appeared anxious, and had difficulty sleeping, all of which were uncharacteristic. On the day of admission she was disoriented, paranoid and aggressive, prompting her family members to call EMS. Vital signs were within normal limits. CT head was unremarkable. Lumbar puncture (LP) revealed 25 white blood cells with 96 % lymphocytes. On initial exam she was alert and oriented but had poor recollection of recent events. Shortly afterwards the patient began screaming uncontrollably and attempted to leave the hospital. She became combative, and appeared to be responding to internal stimuli. She required several rounds of Haldol and Ativan for sedation. Over the next several days, she experienced numerous similar episodes requiring remarkable physical and chemical restraint. An extensive infectious work up was negative, and a brain MRI showed no gross abnormalities. EEG demonstrated cerebral dysfunction in the L temporal and R parasagittal regions. On hospital day 7, a CT scan of the patient's abdomen and pelvis was performed as there was growing concern for a paraneoplastic process. Imaging revealed a large mass encompassing both ovaries. She was taken to the OR on hospital day 9 for bilateral salpingo-oophorectomy. Pathologic examination revealed a low-grade immature ovarian teratoma. She was subsequently started on high dose steroids and plasmapheresis. She experienced minimal neurologic improvement and so IVIG was initiated. Shortly after her last treatment, she began to show recovery in communication and comprehension. Her mental status improved, and she was discharged home on hospital day 44. CSF later returned positive for anti-NMDA receptor antibodies, confirming the diagnosis. Upon outpatient follow-up 10 weeks after presentation, neurologic function was noted to be nearing her baseline, although she had no recollection of her hospitalization or the events leading up to it.

DISCUSSION: Paraneoplastic limbic encephalitis is a challenging illness to diagnose and treat. A form of this that has been gaining increasing attention is anti-N-methyl-D-aspartate (NMDA) receptor encephalitis, which was identified in 2007. Manifestations of this illness include dramatic psychotic symptoms, altered consciousness, seizure-like activity, catatonia, dyskinesias, and autonomic disturbances. It is believed to be an autoimmune mediated disorder that results in excitotoxicity of the NMDA receptors found mainly in the limbic system. Anti-NMDA receptor encephalitis is prevalent in young women and is often associated with benign tumors, the most notable being ovarian teratomas. Common workup may reveal lymphocytic pleocytosis in CSF and abnormal

frontotemporal activity on EEG. Definitive diagnosis is established by the presence of antibodies in CSF. First line treatment includes removal of tumor, if there is one, and combinations of plasmapheresis, steroids and IVIG. Studies have shown that prognosis is improved when the disease is identified and treated promptly. However, there is typically a significant delay in diagnosing anti-NMDA receptor encephalitis as patients are often misdiagnosed with a primary psychiatric illness. It is therefore important to think of this illness once common etiologies of encephalitis have been excluded.

WORKING OUT WITH MINIMAL CHANGE Derek Worley. Lenox Hill Hospital, New York, NY. (*Tracking ID #1938580*)

LEARNING OBJECTIVE 1: 1.) Recognize the need for detailed histories

LEARNING OBJECTIVE 2: 2.) Generate awareness of supplement use in the general population

CASE: A 33 year old previously healthy male presents with 3 days of bilateral lower extremity edema. The patient also endorsed oliguria and urgency during the previous week. Associated symptoms included lethargy, decreased appetite, and weight gain. He denied any family history of renal disease. The patient stated that he lifts weights most days of the week. His diet consists of low sodium, high protein intake, complex carbohydrates, and no vegetables. The patient also endorsed starting a dietary supplement called Tribulus approximately 1 month prior. He denied any other medication or supplement use. On his vitals were stable and his exam was significant for generalized anasarca with +1 pitting edema of the lower extremities to the tibial plateau. The serum creatinine was 1.89 mg/dL and a urinalysis showed >300 mg/dL of protein and moderate urine blood. Based on the findings the patient was diagnosed with a nephrotic syndrome. For further investigation the patient received a percutaneous renal biopsy, which revealed diffuse foot process effacement, supporting a diagnosis of minimal change disease.

DISCUSSION: Minimal change disease (MCD) is a major cause of nephrotic syndrome in children and adults. Lesions of the podocyte or glomerular epithelial cell define this disease. Most cases of MCD are idiopathic. However it can be associated with drugs, neoplasms, infections, and other glomerular diseases. Here we present a patient with suspected tribulus terrestris induced minimal change disease. Tribulus is a derivative of a weed found in warm climates, hypothesized to increase natural testosterone levels. Tribulus terrestris is taken by many because of the desire to enhance athletic performance. There is limited data as to whether or not this supplement increases the body's own ability to produce testosterone. However animal research has proved this substance to be nephrotoxic. There are case reports suggesting that tribulus can be nephrotoxic in humans as well, however the exact mechanism of the nephrotoxicity of Tribulus remains unknown. We recommend that clinicians screen their patients for use of dietary supplements as some clearly can have harmful side effects.

CLINICAL PRACTICE INNOVATIONS (CPI) "SWEETBEATS" DIABETES CLINIC: YOUR ONE STOP SHOP Reena Agarwal¹; Marta Rico²; Carol N. Lau¹; Joanna White¹. ¹Montefiore Medical Center, Bronx, NY; ²Montefiore Medical Center, Bronx, NY. (*Tracking ID #1939147*)

STATEMENT OF PROBLEM OR QUESTION: It is unclear what is the best format to deliver diabetes care to a population with a high prevalence of uncontrolled diabetes.

OBJECTIVES OF PROGRAM/INTERVENTION: 1. To develop a multi-disciplinary "one-stop shopping" approach to diabetes care in order to make a diabetes management visit more convenient for the patient. 2. To integrate residents into this multi-disciplinary setting. 3. To improve the overall diabetes care of our patients

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT: The Bronx has a 12.1 % prevalence of diabetes mellitus, as compared to 8.3 % in the United States. Within our practice the prevalence is 18.2 %, of which 20 % are uncontrolled (have HgbA1c's above 9 %). Our practice is a teaching site for internal medicine residents within a large academic medical center. It is a Federally Qualified Health Center and therefore a referral center for patients who are uninsured or unable to find a provider. Our population includes those with complex medical and psychiatric problems, significant psychosocial needs and low health literacy. We have a large proportion of patients with uncontrolled diabetes, and a continual influx of new patients who have not addressed their diabetes or are recently diagnosed. Our office offers multiple services for these patients including a health educator, dietician, social worker and pharmacist. However, seeing each of these providers quickly increases the burden of visits on our patients and can lead to a

high no-show rate. We developed a weekly "Sweetbeats" diabetes clinic which incorporates a multi-disciplinary team in one clinical session. Patients are referred by providers either at an office visit or when a high HgbA1c is found by laboratory testing. As each patient checks in for their visit, the team huddles and assigns each patient 2-3 providers based on a review of their needs. The residents are integral to the huddle, and each patient sees one medical resident for medication management. We use the "one-stop" shopping approach even for the patient's room assignment: the patient stays in one room and the providers rotate between patients.

MEASURES OF SUCCESS: The evaluation of Sweetbeats diabetes clinic is folded into our Primary Care Medical Home quality indicator monitoring. We monitor the quarterly HgbA1c, and annual LDL and urine microalbumin. We are in the process of improving our ability to track annual podiatry and ophthalmology visits as well.

FINDINGS TO DATE: We are reporting data for the year of 2012. During this time we were referred a total of 151 patients. Our no-show rates range from 30 to 70 % per session with no clear trend over the calendar year. The average HgbA1c prior to their Sweetbeats DM clinic visit was 10.14 %, this improved to 8.99 %. In addition, the average LDL decreased from 106 to 99.9. However, the number of patients who had a urine microalbumin checked decreased from 110 to 72.

KEY LESSONS FOR DISSEMINATION: In an office with multiple resources we were able to develop a multi-disciplinary clinical session for patients with uncontrolled diabetes. This is more convenient for the patient by limiting the number of visits required. For those patients who do come, we have found improved diabetes control. A major barrier is our continued high no-show rate. We are in the process of eliciting some of the reasons behind this poor patient turnout.

A COMPREHENSIVE CLINIC-BASED STRATEGY TO PROMOTE SAFE OPIOID PRESCRIBING FOR CHRONIC NON-CANCER PAIN IN THE PRIMARY CARE SETTING Jocelyn James; Jared W. Klein; Lisa Chew; Joseph Merrill; Sara L. Jackson. University of Washington, Seattle, WA. (*Tracking ID #1939027*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Use of opioids for chronic non-cancer pain, particularly at high doses, carries significant risk without consistently improving function or quality of life; providers, including trainees, find opioid prescribing a particularly challenging aspect of primary care.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Develop and implement opioid prescribing policies and monitoring plans for patients on chronic opioids; 2. Train providers in the delivery of safe and effective chronic pain treatment; 3. Educate patients regarding the risks of opioids and non-opioid strategies for chronic pain management;

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Harborview Medical Center (HMC) in Seattle, WA, is an urban safety-net teaching hospital with a mission to serve medically and socially vulnerable populations. HMC's Adult Medicine Clinic (AMC) has over 60 resident and attending providers and more than 5000 patients, including 27 % with Medicaid and 24 % uninsured. Coexisting medical, psychiatric and addiction disorders are common. As escalating opioid-related deaths in WA State highlighted the need for improved opioid prescribing practices, AMC implemented a clinic-wide strategy to promote safer prescribing of opioids for chronic pain. In 2010, a multidisciplinary committee of primary care providers (PCPs), pharmacists, nurses, a psychiatrist, a social worker, and an addiction medicine specialist developed opioid prescribing policies and protocols. Guidelines address depression and substance abuse screening, drug selection, dose titration, urine toxicology testing, review of the WA State Prescription Monitoring Program (PMP) database, and agreement violations. A ceiling dose of 120 mg morphine equivalents per day (MED) is recommended and providers are encouraged to taper patients on higher doses. Clinic pharmacists create monitoring plans for patients and maintain a registry to track prescribing practices. The opioid review committee meets monthly to review protocols and discuss cases of patients on high doses or with challenging needs, providing recommendations to PCPs. Provider education is an ongoing component of AMC's opioid strategy. Training incorporates best practices in opioid prescribing, non-opioid pharmacotherapy and non-medication treatments such as Cognitive Behavioral Therapy and motivational interviewing skills. Finally, a patient care controlled substances agreement is used

to educate patients about the risks of chronic opioid therapy and set behavioral expectations.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We recorded the number of educational sessions and cases reviewed by the multidisciplinary committee. Clinic registry data allowed us to quantify patients on chronic opioids and those on extremely high (>1000 mg MED) or high (>120 mg MED) doses before and after implementation of the strategy.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): From 2010 to 2013, three or more training sessions on chronic pain management were held each year for residents. The multidisciplinary committee provided recommendations on 99 cases, an average of 2.4 per month. The number of patients receiving opioids for chronic pain fell 39 % from 591 to 358; the percentage on extremely high doses fell from 10 % (n=60) to 2 % (n=7), and the percentage on high doses fell from 35 % (n=197) to 19 % (n=69).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): We created a clinic-wide strategy to promote safer chronic opioid prescribing in a large academic safety-net primary care clinic. Through increased education, communication, and decision support around pain management, we reduced the total number of patients on chronic opioids and the number of patients on high-dose opioids.

A METHODOLOGY USING INTERNET BASED RESOURCES AND WEBSITES TO IDENTIFY COMMUNITY RESOURCES AND SOCIOECONOMIC FACTORS OF PATIENTS ATTRIBUTED TO A GENERAL INTERNAL MEDICINE PRACTICE LIVING WITHIN A SPECIFIC METRO ZIP CODE Scott Joy^{1,2}; Jordan T. Wehe²; Gavriel Roda²; Edward A. Soto²; Cara Campbell²; Aaron B. Galbraith². ¹The Colorado Health Foundation, Denver, CO; ²University of Colorado-Denver, Denver, CO. (*Tracking ID #1936054*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Providing referrals to community resources is a required element for PCMH certification, but community resources are widely dispersed within a given geographical region covered by a general internal medicine practice, and resources that catalog and illustrate these community services are not readily available to patients and general internal medicine practices.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Identify within the metro Denver area the most common zip code address of patients who are attributed to a particular primary care practice. 2. Explore internet based resources/websites that are available to identify physical community resources (recreational centers, churches, schools and parks) and their location within this zip code. 3. Develop a map of these community resources that can be used by the practice and given to patients who live within the particular zip code.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A query of existing billing data was performed to identify the most common address zip code of patients receiving care within a general internal medicine practice. It was determined that the metro Denver zip code 80205 was the most common address zip code for patients within the practice. A team of 4 undergraduate students in the BA/BS-MD program at the University of Colorado Denver was tasked with searching for internet based resources/websites that would provide detailed data on community resources available in this particular zip code. A comprehensive internet search located the following website (www.city-data.com/zips/80205.html) that allowed for detailed evaluation of physical community resources (churches, recreational centers, schools and parks) within zip code 80205. The website www.maps.google.com was used as an additional resource. The Colorado specific website www.piton.org was identified as a tool to identify relevant demographic information within each neighborhood in the specific zip code, including total population, average household income, % persons in poverty, and crime rate per 1,000 persons.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Determine the total number and addresses of physical community resources (churches, schools, recreational centers, parks) available within the targeted zip code. Create a map of the targeted zip code that includes locations of the physical community resources within the targeted zip code. Identify key socioeconomic factors for people living in each of the neighborhoods within the target zip code.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): Our team's analysis found that zip code 80205 has the following physical community resources: 9 Churches 9 Parks 3 Recreational Centers

1 Denver Police Community Resource Center 18 Schools Locations of the churches, parks, recreational centers and schools were placed on an electronic map of zip code 80205 found on the city-data.com website for reference. This document can be printed and given to patients to educate them on community resources available in their neighborhood. Zip code 80205 was found to have 5 distinct neighborhoods with the following socioeconomic demographics. Range of total population in each neighborhood: 3,106 to 12,710, average 5,927 Range of average household income: \$35,519 to \$44,847, average \$40,313 (Metro Denver average is \$55,129) Range of % of persons in poverty: 14.29 % to 31.5 %, average 26.1 % (Metro Denver average is 14.3 %) Range of crime rate/1,000 persons: 53.77 to 125.02, average 71.53 (Metro Denver average is 60.19)

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The existing internet based websites www.city-data.com and www.maps.google.com can be used by any general internal medicine practice within the United States to identify physical community resources for their patients. A map of resources within the zip code can be created from this data and provided to the practice and to the patients living within the zip code to allow all to understand the community resources available. A general internal medicine practice can also use demographic and socioeconomic factors to target clinical and social resources more effectively. Next steps will be to use the detail provided in this search to reach out and collaborate with community leaders to determine best ways to meet the needs of shared citizens living in these neighborhoods to maximize health outcomes.

A NURSE VISIT PROTOCOL COMBINED WITH POPULATION MANAGEMENT REPORTS IMPROVES QUALITY METRICS IN HYPERTENSION
Jason Higdon; Monica Agrawal; Jennifer Zreloff. Emory University School of Medicine, Atlanta, GA. (*Tracking ID #1937459*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): As the focus of healthcare shifts towards providing high quality care for chronic medical conditions, we must develop novel ways to provide better care, meet quality metrics, and manage ever-increasing demands in primary care.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): In a university-based and NCQA recognized Patient-Centered Medical Home (PCMH), we sought to improve the percentage of patients with hypertension who achieved a goal blood pressure of less than 140/90.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our PCMH pilot practice consists mostly of patients on an employer-sponsored health plan. Using a team-based approach we focused on staff education and empowerment, population management reports, and documentation in our electronic medical record to deliver protocol-driven care to our patients with hypertension. 1. An in-service was done with the entire team including all providers, nurses, and medical assistants to reinforce proper measurement of blood pressure including timing, position, and cuff size. Competencies were observed and scored by the team physicians to ensure buy-in and comfort with a nurse visit protocol. 2. A nurse visit protocol was written for hypertension follow-up visits. This included a standard nursing note for our electronic medical record which includes the patient's medication list, an assessment of medication compliance/side effects, current and most recent blood pressure readings, and follow-up of most recent self-management goals. The protocol includes parameters to identify potentially dangerous vital signs. For patients whose blood pressure is not at goal, the nurse automatically makes a 1 month follow-up visit for reassessment. In our patient population this type of nursing visit is offered at no cost to the patient. 3. We developed a monthly hypertension population management report that lists all patients with a diagnosis of hypertension whose last blood pressure anywhere in our system (excluding inpatient and ER visits) was above 140/90. It delineates if their most recent blood pressure reading in our clinic was at goal or not and notes if they have an upcoming appointment. We use this to generate health reminder letters to our patients which are largely delivered through our patient portal.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Each month, we track the percentage of all patients in our clinic who have hypertension whose last reading was <140/90.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): Our baseline percentage of patients at goal was approximately 64 % which was on par with institutional and national benchmarks. Our peak level of patients at goal was 76 % in October 2013 with the largest improvement coming after the implementation of the standardized nurse visit follow-

up for patients who were not previously at goal. Through the end of 2013 we were at 72 % of patients at goal.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. Using standardized, protocol-driven care provides the foundation for team-based care 2. When physicians actively empower and educate team members to provide care beyond their typical roles, more buy-in occurs which leads to improved monitoring and quality of care 3. Access to accurate data is crucial in implementing population based-care for chronic medical conditions

A PANEL MANAGEMENT APPROACH TO SHARED DECISION MAKING FOR COLORECTAL CANCER SCREENING Kathleen Fairfield^{1,2}; Christine Peura²; Elizabeth Herrle¹; Lauren Daniels¹; Mary McDonough³; Donald Medd¹; Deborah Pyle¹; Mark Bouchard³. ¹Maine Medical Center, Portland, ME; ²Maine Medical Center, Portland, ME; ³Maine Medical Center, Portland, ME. (*Tracking ID #1935561*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Use of decision aids (DAs) in shared decision making (SDM) increases patient knowledge, result in greater patient comfort with decisions and improves patient participation in decision making. However, using DA in primary care practice can be cumbersome due to practical limitations on providers recommending and disseminating DAs, the need to arrange appropriate follow up discussions with patients, and ensuring the ability to act on patient decisions in a timely manner.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): (1) To demonstrate the feasibility of a panel management approach to SDM for colorectal cancer screening (CRC) using DAs in primary care with follow up telephone decision support and the ability to order a screening test if chosen by the patient at the time of the decision support conversation. (2) To determine the effectiveness of this approach in varied practice settings.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We identified English-speaking adults between the ages of 50–75 from three primary care practices (all with resident learners) who were not current on CRC screening according to a review of their medical records, which included a transition to Epic during the record review for all three practices. Primary providers then excluded patients who had active serious medical conditions or for whom screening was otherwise inappropriate at the current time. Patients received a CRC DA through the mail that included a booklet, DVD, and a signed letter from their primary care provider. Patients were called 2 weeks after mailing of DA by a member of the medical team (RN or MA) for follow up decision support.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Chart reviews were completed 6 months after the mailing to determine (1) if the patient had been reached for decision support, (2) had completed CRC screening, or (3) reported using the DA and making a decision not to be screened.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): 1,484 DAs were mailed to patients but 258 (17.4 %) patients were found to have been previously screened, medically unfit, transferred, or did not speak English before follow up support, and those patients were excluded from the remainder of the study, leaving an N of 1,226. 663 (54.1 %) were reached for follow up support and 148 (28.7 %) were further excluded from the study, leaving an N of 1,078. Of the remaining 515 patients reached for follow up support, 226 (43.9 %) patients stated they reviewed the DVD/booklet; 77 (34.1 %) declined screening, 41 (18.0 %) were interested in a FIT test, 79 (35.0 %) were interested in a colonoscopy, and 28 (12.4 %) did not make a decision. Two hundred four patients did not review the DVD/booklet: 93 (45.6 %) declined, 21 (10.3 %) were interested in a FIT test, 33 (16.2 %) were interested in a colonoscopy, and 57 (28.0 %) did not make a decision. Further chart review and office visits found two additional patients that had already been screened, leaving a final N of 1,076. Six months has elapsed for 940 patients. Of these, 143 (15.2 %) have completed a screening: 51 (5.4 %) chose a FIT test and 93 (9.9 %) chose a colonoscopy. The 111 (77.6 %) patients that were reached for follow up support were more likely to complete a screening compared to the 32 (22.4 %) who were not reached ($p<0.001$).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The panel management approach to SDM is feasible and required little time on the part of the PCP, but did require a significant amount of time for other office personnel including time for decision support, which increased effectiveness. To sustain this model, EMRs need to be populated with information on prior screenings, and to systematically identify unscreened

patients as they turn 50 or join a practice. This approach, including the help of other team members, provides an opportunity for SDM outside the office visit and could fit well in a patient centered medical home model. The overall effect of this SDM process on increasing screening rates was small in this study, but decision support increased effectiveness.

A PATIENT CENTERED PAIN MANAGEMENT PROTOCOL: A BIO-PSYCHO-SOCIAL APPROACH TO THE MANAGEMENT OF CHRONIC PAIN Katherine Kueny; Tara Turner; Susan Burbach. University of Nebraska Medical Center, Omaha, NE. (*Tracking ID #1935632*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Although chronic pain is one of the most common complaints seen by general internists, it is also one of the most multifaceted and complex conditions to effectively manage in a primary care setting, lending itself well to utilize a patient-centered, bio-psychosocial approach to pain management.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To provide quality and safe chronic pain management by implementing a patient-centered, bio-psychosocial approach to pain management in a resident-run outpatient clinic. 2. To improve the communication and documentation of pain contracts between the ER and outpatient clinic setting. 3. To provide comprehensive resources and education on various strategies for managing chronic pain for all patients seeking treatment for chronic pain.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A bio-psychosocial pain protocol was implemented in a resident-run general internal medicine outpatient clinic, and incorporated as part of our patient centered medical home model. The protocol was developed to standardize clinic management of chronic pain, improve patient education of pain management, standardize the use and management of pain contracts, establish methods of communicating a patient's pain management plan with other departments in the organization, and to incorporate behavioral management of chronic pain as part of the standard treatment plan. The development of the model included perspectives from physicians, nurses, and behavioral medicine clinicians, as an effort to incorporate an inter-professional approach to pain management. As part of the new protocol, every patient who is on a pain contract is required to attend a chronic pain class, taught by behavioral medicine clinicians. Changes have also been made in the EMR to better document the status of pain contracts, so that other departments are aware of this information. In addition, narcotic prescriptions were changed to be written every 28 days, so that refills always landed on the same clinic day with the same attending physician. Every patient with a diagnosis of chronic pain now receives a pain management folder, which includes additional resources and education on pain management.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We plan to evaluate multiple layers of the new chronic pain protocol ranging from patient satisfaction, adherence to pain contracts, self-management behaviors, depressive screening scores, and frequency of ER visits. We plan to use qualitative metrics to gather patient perceptions and satisfaction tied to the new protocol and chronic pain education class. Utilizing data on our clinic's standard PhQ-2 and PhQ-9 depression screenings, we will assess the impact a comprehensive, bio-psychosocial approach has on depression symptoms. We have worked with the university emergency room to develop a plan for researching the impact of the protocol changes on frequency of emergency visits. We also plan to use quantitative measures to assess a change in patient's self-management behaviors following the education class. We anticipate an increase in adherence to pain contracts due to incorporating the patient more in the pain management plan from the beginning of treatment.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): The new protocol has been in place for 1 year now. In response to the documentation changes related to the protocol, continuity and consistency of pain management treatment plans have improved particularly between the ER and our particular outpatient clinic. This has reduced the frequency of miscommunication and improved consistency of treatment plans between the inpatient and outpatient setting. The integration of behavioral medicine as part of the standard pain management protocol has increased our ability to treat co-morbid psychosocial conditions that have been reported to exacerbate chronic pain. Also, physicians have reported less frustration with narcotic refills, since moving to 28 day refills ensuring that the same physician is responsible for refills.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

Treating chronic pain from a bio-psychosocial framework has reduced frustration and miscommunication among providers. Patients benefit from a focus on written and verbal education regarding pain management. Incorporating and assessing biological, psychological, and social factors from the start of treatment assists the physician and patient in developing a more comprehensive and effective management plan. Standardizing the clinic's protocol on pain management has improved the consistency of education and

resources that patients are exposed to. It is yet to be determined the long-term impact this new protocol has on narcotic use and patient/provider satisfaction. We are also revising the program to better monitor attendance of the chronic pain education class and adherence to pain contracts.

A RANDOMIZED CONTROLLED TRIAL OF A DAILY "I.R.A." MEDICAL HUDDLE Rahul Vanjani¹; Nancy Chang¹; Maria Arkipoff¹; Steven Shea^{1,2}; Jessica R. Singer¹. ¹New York Presbyterian Hospital - Columbia University Medical Center, New York, NY; ²Mailman School of Public Health - Columbia University, New York, NY. (*Tracking ID #1936985*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Providers and staff at academic clinics often work in silos rather than as integrated members of a medical team, and this may result in low job satisfaction, poor work environment and feelings of burn out, ultimately resulting in inefficient care delivery.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To implement a daily medical huddle including all members of the patient care team with the following objectives: 1. Create a structured system for communication about clinic logistical and patient care 2. Foster social cohesion—a sense of team—between team members 3. Improve work satisfaction and decrease burnout among team members

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We conducted a randomized controlled trial to pilot a daily medical huddle from August to November 2013 in an urban, academic, joint faculty and resident outpatient primary care practice that provides 75–80,000 visits/year. The clinic has four structurally similar modules, each with relatively consistent teams of staff and providers. Two of the four modules in our clinic were randomized to the huddle intervention. The huddle was based on a customized framework we designed entitled I.R.A. (introduction, reflection, anticipation). Clinical duties were suspended each morning at 9:00 am to allow all team members (attending physicians, residents, medical assistants (MAs), registered nurses (RNs), front desk staff) in the intervention modules to congregate in a circle in order to engage in a process of organized introduction by name and role, reflection on what went well the day prior and what did not, and anticipation of upcoming logistical problems or patient issues. The huddles were led by the medical assistant in order to empower a non-clinical member of the team. Huddles generally lasted 5 min and team members were encouraged to stand rather than sit as a way of promoting efficiency and remaining cognizant of time.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): An 8-item modified version of the Staff Experience Survey from the University of Chicago and the Commonwealth Fund was used to measure job satisfaction, burnout, problem-solving, efficiency, communication and work environment characteristics on a 5 point Likert scale. The survey was administered to a convenience sample of staff and providers at baseline and upon completion of the 4 month intervention period. For each survey respondent, a change score was calculated for each of the items (score after intervention - score prior to intervention). For bivariate analysis, t-tests were performed to assess differences in item scores between groups. Linear regression with interaction terms was used to test for differential response to the intervention by providers and staff members.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): We surveyed 48 people in our clinic and received responses from 41 individuals (response rate 85 %); 45 % were providers and 55 % were RN/MA/front desk staff. About 2/3 of the respondents were from the intervention modules. Prior to the intervention, the responses from control and intervention modules did not differ on any of the items. However, physicians were more likely to report lower feelings of job burnout (2.2 ± 0.6 vs 3.0 ± 1.1 , $p < 0.01$) and higher job satisfaction (4.1 ± 0.9 vs 3.4 ± 0.9 , $p < 0.01$) compared with non physicians staff members. Physicians were also more likely to report that their module functioned as a team (3.3 ± 0.9 vs 2.7 ± 0.9 , $p = 0.05$) and feel like the work they perform is appropriate for their level of training (3.9 ± 0.7 vs 3.3 ± 1.0 , $p = 0.03$). After the intervention, there were no significant differences between control and intervention modules in any of the items. We found that providers and staff responded differently to the intervention. Providers in the intervention modules perceived an improvement in teamwork (p -interaction = 0.02) and problem solving (p -interaction < 0.01) compared with staff; there were no differential responses in the other items.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our pilot RCT demonstrated that a structured daily huddle can improve teamwork and

problem solving from the perspective of the physician providers, but similar improvements were not noted by other staff members. As many clinics have already or will soon implement huddles as part of the patient centered medical home, it is important to recognize that huddles may have unintended consequences and effect groups differently. We did not see improvement in job satisfaction, burnout, efficiency, communication and work environment characteristics which may be attributed to small sample size, non-blinded design, short intervention period, or occasional cross-over of staff between intervention and control modules. We also note that our choice of downstream benefits to assess in the survey may not have included some relevant processes such as improved patient care and culture of safety. Based on overwhelmingly positive anecdotal feedback from staff and providers, the huddle has been adopted by all modules in our clinic. Next steps will include sharing our findings with the teams and seeking suggestions for how to improve the huddles.

A RESIDENT-LED INTERVENTION TO IMPROVE TEAM-BASED CARE IN AN INTERNAL MEDICINE CONTINUITY CLINIC Stephanie Nothelle; Eunice Yu; Laura Hanyok. Johns Hopkins Bayview Medical Center, Baltimore, MD. (*Tracking ID #1937682*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Internal medicine trainees need to master the skills of delivering high-quality care for complex patients in an outpatient, team-based patient-centered medical home; however, many trainees still practice in clinics that have not adopted this care model.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To design a low-cost, low-time intensity intervention to promote team-based care in the house staff outpatient practice 2. To improve understanding of roles and value of team members among residents

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Two interventions were instituted, pre-clinic huddles and monthly multidisciplinary meetings. The interventions took place in the General Internal Medicine practice at Johns Hopkins Bayview Medical Center, an academic medical center, where 45 residents in both primary care and categorical internal medicine tracks are primary care providers. In this practice, resident and attending physicians are assigned to one of three clinical “pods” where a consistent team of medical assistants (MAs) and medical office assistants (MOAs) works. Pre-clinic huddles took place in the 15 min prior to the first scheduled clinic appointment in each of these pods and included the house staff providers, MAs, and MOAs as well as an attending physician. The huddle started with a non-medical “question of the day” that also served as a team building exercise. The MAs reviewed issues that could contribute to workflow limitations that day, such as staffing shortages or vaccine availability. Then, each resident briefly reviewed their list of patients with the team, with a focus on making staff aware of workflow issues such as need for an interpreter or for procedure setup. Multidisciplinary meetings took place once a month and were focused on Medicare and Medicaid patients identified as high-risk for health care utilization by the Johns Hopkins Community Health Partnership (JCHP), a separate program. The team was comprised of a nurse case manager, a community health worker, a behavioral health coach, resident physicians, and an attending physician. The nurse case manager led these meetings by reviewing each active or newly enrolled patient who had a house staff provider and inviting the team to comment on active problems. Each team member shared information on the patient and a problem-solving discussion was initiated. At the conclusion of discussion, the plan of care was updated appropriately in the EMR.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Pre-clinic huddles are being evaluated by an anonymous survey administered to residents and medical office staff prior to initiation of huddles and then 6 months later. The survey uses a Likert scale to measure how frequently house staff discuss patient and workflow issues with MAs and MOAs prior to a clinic session, the perception of working in teams in clinic and whether or not the huddle is enjoyable. The survey also asks for open responses regarding usefulness and areas for improvement. The multidisciplinary meeting is being evaluated 6 months after implementation using quantitative and qualitative survey questions. Using Likert scale-based responses, the survey assesses perception of the impact of the meetings on patient care, house staff understanding of the roles of each team member including themselves, and understanding of the value of multidisciplinary care as a result of the meetings. Open response questions again assess usefulness and areas for improvement.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE “FINDINGS WILL BE DISCUSSED”): Thirty-one of the 45 eligible house staff completed the pre-intervention survey. Seventy-three percent reported that they touched base with MAs and MOAs prior to clinic sessions less than half of the time, and 22 % never did. On a scale of 1-4 [with 1 meaning not at all and 4 meaning a great deal], house staff responded on average 3.6 that they feel that they work in teams with MAs and MOAs, while MAs and MOAs responded on average 2.7. Six months after the intervention, medical office staff view the huddles favorably and feel more strongly that they are working in a team with house staff, rating of 3.17 out of 4. Results of the post-intervention resident surveys on huddles and multidisciplinary meetings will be available in February 2014.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. Prior to the establishment of dedicated time for collaboration such as a huddle, most house staff in our practice did not discuss patient care regularly with other team members such as MAs and MOAs. 2. Small, low cost interventions such as pre-clinic huddles that bring together providers and office staff regularly can improve team based care. 3. Non-physician team members may perceive teamwork differently than physician team members.

A SYSTEM FOR TRANSITIONAL CARE MANAGEMENT IN THE PATIENT CENTERED MEDICAL HOME Carol R. Fleischman. University of Pennsylvania, Radnor, PA. (*Tracking ID #1940768*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The patient centered medical home is considered a key factor in preventing readmissions, yet our hospitalized patients may be falling through the cracks; if we leave our follow up plans to individual practice, and do not have a system, our patients may be at risk for readmission due to not getting timely or medically relevant follow up care

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Centralize our admission notification and increase our awareness of when patients are admitted to any hospital in our region Accomplish telephone follow up with the patient promptly upon discharge, performing the key functions of medication reconciliation, and assessing any unmet needs. Ensure prompt follow up appointment with the patient’s primary care internist or relevant subspecialist.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Penn Medicine at Radnor is an eight-physician general internal medicine practice located in a suburb of Philadelphia, part of the Clinical Practices of the University of Pennsylvania. Patients from Penn Medicine at Radnor can be admitted to a number of University of Pennsylvania Health System hospitals as well as other hospitals in our region which are not affiliated with our health system. Our health system sends an electronic discharge notification to the primary care physician. The outlying hospitals all have disparate means of notifying the patient’s primary physician of a hospital stay. Notification of admissions and discharges was sporadic and unreliable. Furthermore, each physician dealt with admission notifications differently, and full schedules sometimes made it difficult to schedule follow up visits after hospitalization. Our goal was to devise a centralized system to track our admissions and collect relevant data about them at the practice level. All admission and discharge notifications, whether emails, faxes, or phone calls, were routed to one person as well as continuing to be routed to the patient’s primary physician. All admissions were then logged onto monthly spreadsheets which were placed on an external drive that was accessible yet secure for data analysis. We hired a care management RN, who makes follow up calls to patients after discharge and completes a Care Management form in our electronic medical record (Epic). We now also track the calls and patient’s follow-up visit date on the admissions spreadsheet.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): This system measurably improved our timely awareness of admissions and discharges. Between September 2011, when we fully implemented this program, and now, there was a steady increase in the number of admissions we captured per month. In recent months, we are tracking a stable average of about 100 admissions per month. We also achieved a marked improvement in scheduling 7–14 day follow up visits. Patient satisfaction survey. We created and distributed a survey to assess patient perception of whether the follow up calls assisted them with medication concerns, efficacy in self-management, follow up care, and overall sense of continuity and security regarding their care. The data collection for this survey is currently underway.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE “FINDINGS WILL BE DISCUSSED”): Between September 2011 and September 2013 the percentage of patients receiving a follow up within 7 to 14 days of discharge

increased from 27 to 60 %. In 2011, 20 % of discharged patients did not receive a follow up visit. In 2013, less than 1 % did not receive a follow up visit.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

Transitional care management cannot be left to chance. We designed a simple yet reliable system for tracking admissions and discharges, identifying problems after discharge, and scheduling follow up care. We leveraged existing resources within our health system (Events of Interest, Care Connectors) and reached out to hospitals that are not part of our system. Having a point person or small team responsible for connecting discharged patients to their follow up care is a much better system than relying on each physician's diverse practice in receiving faxes/records regarding discharges and getting patients in. A care management nurse, using a templated phone encounter form, can quickly and efficiently uncover lapses/needs and assess patient status. Efficient and timely follow up also requires dedicated session time for hospital follow ups. Much effort is being expended on the hospital side of the readmission equation. However, outreach from the outpatient setting—the patient's medical home—may be just as important in ensuring continuity and preventing readmissions.

A UNIQUE MODEL FOR MULTIDISCIPLINARY BEDSIDE ROUNDS IN AN ACADEMIC TEACHING HOSPITAL Eric A. Young^{1,2}; Jaime Pauk¹; James M. Beck^{1,2}; Mel Anderson^{1,2}; McKenna Burck¹; Stephen Szapor¹; Adam Roberts¹; Chad Stickrath^{1,2}. ¹Denver VA Medical Center, Denver, CO; ²University of Colorado School of Medicine, Aurora, CO. (*Tracking ID #1939319*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Valuable models for improving interprofessional communication through multidisciplinary bedside rounds (MBR) have been described in the literature; however, these models often depend upon geographic localization of patients and providers.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Our goal was to create a sustainable model for MBR on a medical unit in an academic teaching center without geographic patient or provider localization.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our hospital is an academic, tertiary care teaching center with five housestaff teams caring for patients on three medical wards and in an open ICU. As part of a Rapid Performance Improvement Workshop (RPIW) aimed at improving patient flow, we developed a strategic plan for implementing MBR on a pilot 27-bed medical unit. Key components of the intervention included: 1. Shifting of the morning medication administration time from 9 am to 7 am, allowing nurses to join the resident teams on bedside attending rounds 2. Creation of a Provider Sign-In Sheet posted at the charge nurse desk with contact information for both nurses and physicians caring for each patient 3. Development of a protocol for housestaff teams to use the Provider Sign-In Sheet and Cisco® phones to quickly identify and contact each patient's nurse prior to starting bedside presentations 4. Creation of a system for auditing day-to-day completion of multidisciplinary rounding using nursing self-report 5. Implementation of bimonthly displays of each housestaff teams' frequency of multidisciplinary rounding, coupled with rewards for performance

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The intervention was evaluated using two methodologies: 1. Quantitative improvement in the frequency of physician-to-nurse communication during teaching rounds was assessed using daily nursing self-reports. 2. Qualitative evaluation using a 28-question survey adapted from available instruments and refined through cognitive interviewing. Constructs included overall satisfaction and perceived impact on teamwork culture, interprofessional communication, nurse job satisfaction, provider workload and impact on future practice. The survey was administered anonymously to nurses, medical students, residents and attending physicians who had participated in MBR in the preceding 5 months. Results were analyzed using descriptive statistics and differences between provider groups were assessed using Fisher's Exact Test.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE “FINDINGS WILL BE DISCUSSED”): Our MBR initiative has been successfully employed for 5 months. During that time we have gathered daily nurse self-reports for 759 patient encounters, out of which multidisciplinary rounding occurred in 669 (success rate 88 %). Previous observational work from our hospital demonstrated that physician-to-nurse communication on rounds occurred only 5 % of the time; thus, we have achieved an 83 % improvement in interdisciplinary communication during medical teaching rounds. Ninety-five out of 142 providers completed the qualitative

survey (67 %). In general, satisfaction was high, with similar percentages of nurses and physicians agreeing that the initiative should be expanded to other wards (100 % and 97 % respectively, $p=1.0$). Eighty-five percent of resident physicians agreed that MBR should be incorporated at other hospitals in which they train. Physicians and nurses agreed that mutual understanding of care plan changes increased since the initiative began (nurses 93 % and physicians 94 %, $p=1.0$). The perception of improved collaboration was similar, with 94 % of nurses and 93 % of physicians agreeing that they worked more often as a well-coordinated team ($p=0.68$). Nursing job satisfaction improved, with 65 % reporting increased job satisfaction since the onset of the MBR initiative. MBR did not appear to significantly impede provider workflow as 87 % of nurses reported MBR was an efficient use of their time. Similarly, 85 % of physicians indicated that MBR only prolonged rounds by 10 min or less. Finally, MBR did not appear to hinder the educational value of teaching rounds, with 40 % of residents reporting that MBR increased the educational value of rounds and the other 60 % reporting no effect.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1)

Multidisciplinary rounding is feasible in an academic institution without geographic patient and provider localization 2) Key lessons we have learned: a. The process for communication must be streamlined b. The system should strive to be workload-neutral c. Sustainability requires some means of auditing and providing performance feedback

ACTIVE REFERRAL MANAGEMENT - A SPECIALIST/PCP COLLABORATION TO ADDRESS ACCESS, VALUE, AND EXPERIENCE Sandhya K. Rao¹; Ryan Thompson¹; Creagh Milford¹; Nancy Wei³; Calvin A. Richardson²; Sara Hoffman²; Timothy Ferris¹. ¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Physicians Organization, Boston, MA; ³Massachusetts General Hospital, Boston, MA. (*Tracking ID #1939604*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can a specialist-based referral review program reduce avoidable specialist visits by replacing the office based consultation with non-visit based alternatives for physician to physician consultation?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Develop a mechanism for referring clinicians to access specialist expertise through alternatives to face to face patient encounters 2. Reduce wait days and total visits per patient 3. Improve patient and provider experience

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): There are two related components to our intervention: 1. Active Referral Management: Specialty identifies referral reasons for which a face to face visit may be avoidable. Using our electronic referral management platform, the specialist reviews all incoming referrals in those areas weekly. When appropriate, the specialist emails the referring physician directly with recommendations, either to replace the visit, or to suggest additional tests or therapies to initiate prior to the specialist visit. Patients identified as urgent are triaged appropriately. Specialists are paid a quarterly stipend based on projected volume of incoming referrals 2. Curbside Consults: In two of our participating specialties, clinicians will have the option to submit a request for a “MD to MD” consult. Both take place in the ambulatory primary care and specialty practices of an urban academic medical center which is part of an integrated delivery system and uses both an electronic medical record and referral management system.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Key Process Measures 1.% of total incoming referrals reviewed: Aim is approximately 50 % to ensure broad impact. However, selecting appropriate referral reasons for review drives overall efficiency of the program, so some specialties will be lower. 2.% of referrals alternatively managed: Core performance measure of program; reflects both effectiveness of our case selection as well as utility of program. 3.% of referrals with pre-consultation tests/treatment recommended to referring MD: Secondary process measure which may drive reduction in scheduled follow up visits to specialist, improved patient/provider satisfaction, and both clinical and patient-reported outcomes 4.% of referrals with visit scheduled urgently: Measure of collateral benefit in which referrals not initially flagged for urgent scheduling are triaged by specialist Outcome Measures 5. Wait days—expect to reduce as visits are deferred 6. Referral rate—expect to reduce as PCPs are educated 7. Total visits per unique patient—expect to reduce with reduced follow up visits 8. Lab/Imaging utilization per referral—expect to reduce with PCP education 9. Patient/patient

satisfaction—expect to improve with improved timeliness Balance Measures 10. Cost per visit avoided 11. Time per visit avoided

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *â€œFINDINGS WILL BE DISCUSSEDâ€*): Diabetes: approximately 6 months Percentage of referrals reviewed - 100 % Number of referrals reviewed - 359 % alternatively managed - 13 % with previsit planning - 30 % Outpatient capacity gain - 60 h over 6.5 months Specialist time per visit avoided - 1 h Thyroid: approximately 5.5 months Percentage of referrals reviewed - approximately 10 % Number of referrals reviewed - 40 % alternatively managed - 55 % with previsit planning - 0 % Outpatient capacity gain - 11 h in 5.5 months Specialist time per visit avoided - 30 min General Endocrinology: 1 month Percentage of referrals reviewed - 50 % Number of referrals reviewed 93 % alternatively managed - 18 % with previsit planning - pending Outpatient capacity gain - 17 h Specialist time per visit avoided - 1 h Total of 85 visits avoided, approximately 75 h of clinical time invested. Cost at the time of writing is approximately \$115 per visit avoided.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

Through our three pilots thus far, we have learned that together, PCPs and specialists are able to manage a significant portion of referrals through non-visit based activities. Specific lessons include: 1. Process mapping is key: Without developing a detailed, interdisciplinary understanding of the existing referral process, overlaying this new process will be disruptive and of limited value. 2. Use the PDSA model during all stages of implementation: With the high potential for dropped balls, unscheduled appointments, and confusion for patients/providers, weekly interdisciplinary huddles during which key process indicators and cases are reviewed are critical. 3. Well defined clinical scope, focusing on questions most appropriate for non-visit based consultation is critical to achieving efficiency, but may limit overall impact. 4. A quarterly stipend based payment for 1–2 clinicians per specialty, as opposed to a fee-for-service model, encourages an efficient, “programmatic” orientation. 5. Our progress to date has required approximately 75 h of specialist time to avoid 85 visits. Over time, we hope to improve the precision with which we define the scope of referrals reviewed to optimize our use of specialist time.

ADDRESSING FREQUENT UTILIZATION OF THE EMERGENCY DEPARTMENT Paras Mehta; Animita Saha; Ethan Sherrard; Tamara D. Burdon; Joseph Brancatello. Carolinas Medical Center, Charlotte, NC. (*Tracking ID #1941752*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Frequent ED utilizers' (FUEDs) multiple physical and behavioral health needs are not adequately addressed in the ED resulting in the overutilization of high-cost, low-value services.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES):

1. Reduce number and frequency of emergency department visits.
2. Educate patients about services provided within Medical Home and link to services as needed.
3. Utilize integrative care team to reduce costs of patient care.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This pilot was conducted in a hospital-based inner city clinic where majority of patient population is uninsured or underinsured. The entire program started with formation of an interdisciplinary team comprised of the clinic Directors, acupuncturist, behavioral health counselor, social worker, patient navigator, care managers and program coordinator. We used the hospital system's billing system to identify FUEDs to invite to the Drop-in Self-Management Group. The targeted population has been able to access the clinic, as evidenced by at least one visit in the past 2 years. The main innovative and novel intervention is a once a week, Drop-In Self-Management Group (DISMG) held in the clinic location. Patients who attend were provided with a light snack and transportation help. The purpose of the DISMG are: 1. Intensive care management with very low Care Coordinator to patient ratios. 2. Behavioral health services on-site using co-located therapists, and linkage to a behavioral health provider as needed. 3. Linkage to a PCP in the office 4. Education about how to appropriately navigate the healthcare system 5. Referrals to community resources based on need 6. Acupuncture is offered to interested patients to help address the biopsychosocial continuum in patients with high levels of anxiety or chronic pain. 7. Self-management support is enabled by motivational interviewing. Participants are given a toolkit containing disease-specific educational resources and Templates. A patient coordinator will make regular contact with the targeted patients using their preferred method of communication. When a patient does visit the ED, the hospital's Social Workers will re-educate the patient and will close the communication loop with the Clinical Care Coordinator to follow up with the patient the next day. Following a

hospitalization, a transitional care visit may occur telephonically, in the clinic, and/or in the patient's home, depending on the patient's need.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The most important indicator of success is how well the participating FUEDs are linked with available resources. Several factors that contribute to success are successful linkage to a PCP and behavioral health counselor (if necessary). An increase in use of these low-cost services indicates improved patient understanding of how to properly utilize healthcare services. We are also examining the effect of the program on the patients' perception of how well they can manage their health effectively; self-efficacy plays a tremendous role in an individual's overall health status. The effectiveness of the program is ultimately gauged by the reduction of ED visits and associated costs. The greater the reduction in costs, the greater the success of the program.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

All patients identified as being a FUED eligible for our program were successfully linked with a PCP. We realized a 37 % reduction in ED use, with annual number of visits dropping from 13.4 to 8.4. This equates to a 1.94 million dollar estimated reduction in annual charges for the 16 patients who have attended at least one group. The availability of drop-in medical appointments after group averted at least two visits to the emergency department. Eighty-eight percent of the patients received social work services, while 25 % see the integrated behavioral health counselor weekly. All uninsured patients were linked with the sliding scale department and were eligible for reduced-cost care or government-subsidized insurance, impacting the uncompensated care provided by the clinic. All group participants have a behavioral health diagnosis and multiple comorbidities. A supportive group environment is essential for maximum patient benefit. Most group participants have chronic pain. Incorporating acupuncture proved to be effective in reducing pain by average of 30 %.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

The process should start with team building with members who play key role in transitioning patients from ED to their medical home. Key points to remember after the initial phase are: 1. Motivational Interviewing to promote patient engagement and self-management, group facilitator needs to be trained in this technique 2. Intensive care management and social work involvement for educating patients about available services within clinic or community 3. Addressing Behavioral Health issues 4. One specific group model will not fit every practice, need to tailor to population or practice

ADOPTION AND UTILIZATION OF E-CONSULTS IN A VETERANS AFFAIRS HEALTHCARE SYSTEM Varsha Vimalananda¹; Gouri Gupte³; Justice Clark²; Jay D. Orlander²; Steven R. Simon². ¹Center for Health Organization and Implementation Research (CHOIR), Bedford, MA; ²VA Boston Healthcare System, Boston, MA; ³Boston University School of Public Health, Boston, MA. (*Tracking ID #1926077*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Patient-centered medical homes (PCMHs) should improve patient access to healthcare; however, access to specialists may be limited by long distances and wait times, and PCPs often lack ready access to specialty expertise.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES):

To improve access to specialty care for ambulatory patients and PCPs through electronic consultations (e-consults).

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Setting: VA Boston Healthcare System (VABHS) provides primary care through PCMHs to 32,000 Veterans at 3 hospitals and 8 community-based clinics. It is the main referral center for the New England VA Network. Implementation: E-consult implementation for VABHS medical specialties began in 1/2011. Discussions with primary care leadership and emails to PCPs described the availability and purpose of e-consults. By early 2013, e-consults had expanded to include most clinical services, including mental health and pharmacy. Any VABHS provider can request e-consults. Providers at some other New England VA facilities also have limited access to VABHS e-consults. Process: E-consult requests generated in the electronic health record are routed to the consulting service. Within 3 working days, specialists are expected to initiate a dialogue with the requesting provider or convert the e-consult to a traditional patient appointment.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We examined trends in adoption and utilization of e-consults at VABHS quantitatively and qualitatively. We identified the most common requesters,

recipients, requester-recipient service dyads, and requesting provider types. We measured the median time to completion. We then examined the full text of e-consult requests and responses from primary care and between the commonest requester-recipient dyads to better understand e-consult utilization. We are now conducting semi-structured interviews with key stakeholders (leadership, administrators, clinicians).

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE “*FINDINGS WILL BE DISCUSSED*”): Within VABHS, we found: - Top requesting Departments: Medicine (59 %), Surgery (35 %), and Other (6 %) - Top requesting Sections within Medicine: Primary Care (76 %), Pulmonary (4 %), Cardiology (3 %). - Top requesting Sections within Surgery: Orthopedics (41 %), General Surgery (15 %), Optometry (11 %) - Top recipients: Cardiology (11 %), Orthopedics (11 %), Sleep (11 %), Hematology (10 %), and Pulmonary (5 %). - Top requester-recipient dyads: Orthopedics-Orthopedics (65 %), Optometry-Ophthalmology (18 %), Ophthalmology-Optometry (6 %) - 591 intra-specialty e-consults; 85 % within Orthopedics. - Requesting provider types: NPs (34 %), MD attendings (24 %), MD residents/fellows (10 %). - Median time to completion across specialties: 2.2 working days (IQR 0.9–9.6). On review of e-consult full text and in initial interviews with key stakeholders, we found both expected and unexpected uses of the technology. The majority of e-consults requests are clinical. Expected clinical uses include requests for data interpretation and advice on workup and treatment. Unexpected clinical uses vary. For example, we noted questions about workup prior to a scheduled specialty visit, and e-consults to Infectious Disease from a long-term care unit (inpatient) as a means to address non-urgent issues. Orthopedics places most of the intra-service e-consults as a means to document a detailed pre-operative chart review. There are multiple examples of administrative uses of e-consults, all of which represent unexpected use. For example, Pulmonary receives e-consults as a mechanism for granting access to low-dose lung cancer screening CTs, currently a limited resource for which Pulmonary is the gatekeeper. In Optometry, e-consults are commonly used for appointment scheduling.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): E-consults are frequent at VABHS. Nearly one-third originate from clinicians outside VABHS, representing robust use of the e-consult mechanism to improve specialty access for patients at locations with more limited specialty services. Within VABHS, as intended, Primary Care is the most frequent Section utilizing e-consults. Response time is generally satisfactory but widely variable. Access to specialty clinical input is a common use of e-consults. Surprisingly, we find many examples of the e-consult mechanism being utilized for other clinical and administrative uses. These represent unexpected ways that e-consults are used to achieve electronic communication and documentation within and between specialties. While these applications may meet the needs of the institution, providers and patients, they do not fulfill the original intention of e-consults. Therefore, measuring the volume of e-consult use alone may provide misleading and insufficient information in the assessment of improved patient and PCP access to specialty care. Further investigation is needed to better understand the processes leading to wide variation in response time; the rationale for unexpected uses of the e-consult mechanism; and what features of the e-consult program represent valid measures of quality care.

AN INTERDISCIPLINARY INTERVENTION TO REDUCE THE RISK OF ADVERSE EVENTS IN HOSPITALIZED PATIENTS WITH NUT ALLERGY
Christina Lee¹; Barry Schlossberg²; Sally Wong²; Daniel I. Steinberg¹. ¹Beth Israel Medical Center, New York, NY; ²Beth Israel Medical Center, New York, NY.
(Tracking ID #1933394)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): A sentinel event of anaphylaxis in a staff member revealed that food items on the hospital menu were improperly labeled as to whether they contained nuts, prompting concern that patients with nut allergy were at risk for adverse events.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Ensure that no nut-allergic patient suffers an allergic reaction to improperly labeled hospital food. 2. Explore the process of how information about patient food allergy is documented in the medical record.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A medical resident ate a turkey salad prepared by the hospital food service and developed immediate abdominal pain and urticaria. The resident had a history of anaphylaxis to nuts, and went to the ED where anaphylaxis was diagnosed and treated. The turkey salad was found to contain walnuts but was not labeled as such. The resident was concerned that other food items may not be

properly labeled and that patients with nut allergy could be at risk for anaphylaxis. The prevalence of nut and/or peanut allergy in the general population is reported as up to 1.4 %. Tree nuts (of which walnuts are a sub-type) are one of eight foods that account for 90 % of all food-allergy reactions (<http://www.cdc.gov/healthyouth/foodallergies/>). The resident and medicine residency program director contacted the directors of food services and of nutrition. Review of the hospital menu found that three items containing nuts were not properly labeled. An additional patient safety issue was identified. Our institution's food service uses software (CBORD Nutrition Service Suite) to select foods compatible with a patient's allergies. We discovered there is a delay in patient allergies being entered into CBORD. This system does not automatically receive allergy information from the computerized physician order entry software (GE Centricity Enterprise) that providers use to record patient food allergies upon admission. Manual information transfer between these systems is required, resulting in a window of up to 12 h in which patients could be served foods they are allergic to. Two solutions were considered—consistent labeling of all foods containing nuts, or removal of nuts from all food served in the hospital. The latter was chosen as it was more reliable, simpler and did not result in any loss of nutritional value.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. Ability to remove all nuts from food items on the hospital menu. 2. Closing the communication gap between our computerized physician order entry (CPOE) and our food services database.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE “*FINDINGS WILL BE DISCUSSED*”): 1. Within days of our interdisciplinary intervention and a review of the menu, nuts were removed from all hospital food items. 2. To date there have been no further reported events of nut allergy to food prepared in the hospital kitchen. 3. An ongoing goal is to correct the delay in information transfer between our CPOE and our food services database.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): We present this case to point out that it cannot be assumed that all hospital food menu items are clearly labeled as to whether they contain nuts or other food allergens. In addition, providers should be aware that a delay in communication regarding patient food allergies may exist between their institution's CPOE system and the food services database used to generate patient meals. Such a delay could jeopardize patient safety. In this case, we identified a risk of nut allergy, however the same question we asked and process we followed could be applied to other food allergens (for example gluten, eggs or dairy). Different food allergens may require different solutions. In the case of nuts, complete removal from the menu was feasible. For eggs and gluten, proper labeling may be a more practical approach. We found that engaging an interdisciplinary team consisting of a resident, a program director, and food services and nutrition staff was easy and effective. Automatic and more immediate communication of patients' food allergies to a hospital's food service should be the goal. Efforts continue at our institution to solve this issue.

ARE YOU EX-FOLEY-ATING? A HOSPITAL-WIDE INTERVENTION TO DECREASE URINARY CATHETER USE, INCLUDING NURSE-DIRECTED POSITIVE-REINFORCEMENT STRATEGIES Jennifer Meddings²; Cynthia Budelmann¹; Heidi Reicher². ¹Greenville Health System-Laurens County Memorial Hospital, Clinton, SC; ²University of Michigan, Ann Arbor, MI. *(Tracking ID #1939856)*

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Encouraging nurses to remove unnecessary urinary catheters quickly is challenging and important because nurses often are required to perform more bedside tasks regarding incontinence after catheters are removed.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To reduce unnecessary Foley catheter use and catheter-associated urinary tract infection rates, with a focus on education and positive-reinforcement strategies for nurses.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In a 90-bed acute care community hospital with 8 critical care unit beds, several interventions were implemented in 2012 including: 1) February hospital policy regarding urinary catheter use requiring catheters to be ordered by physicians only for approved indications, daily assessment of necessity, standard expectations for bedside care regarding placement and maintenance, and encouragement for nurses to remind physicians to remove unnecessary catheters; 2) March 2012 entry into the ‘On-the-CUSP: STOP CAUTI’ program from the Agency for Healthcare Research and Quality (<http://www.onthecuspstopcathi.org/on-the-cuspstop-cauti/>) involving educational toolkits and data collection resources to reduce CAUTIs, with feedback of Foley catheter

utilization rates to nurse leaders and units; 3) April 2012 purchase and training for bladder scanner; 4) July 2012 initiation of the "Are you ex-Foley-ating" campaign by the infection preventionist to encourage nurse removal of catheters including entertaining nurse-humor posters, daily rounding by the infection preventionist with nurses (for positive reinforcement and just-in-time education), monthly feedback and by rewarding each catheter removal with small wrapped gift with an appreciation note (exfoliating cream for the first catheter removal, and candy for additional catheter removals).

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Before-and-after hospital-wide and critical care unit rates of Foley catheter utilization (i.e., ratio of Foley catheter days to patient days) and catheter-associated urinary tract events were monitored on monthly basis, with monthly feedback provided to each unit.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *"FINDINGS WILL BE DISCUSSED"*): Hospital-wide urinary catheter use ratios in 2011–2013 varied between 0.17 and 0.30, before and after interventions, with no sustainable reduction from an average of 0.2. CAUTI events also did not decrease, yet the CAUTI definition (as defined for National Healthcare Safety Network surveillance reporting) also changed over time. Critical care unit measures of urinary catheter use and CAUTI events varied widely, not unexpectedly given only 8 beds. Unfortunately, despite multiple interventions including an enthusiastic response for the "ex-Foley-ating" nurse-directed interventions, no sustained reduction in urinary catheter use was demonstrated.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): In this small community hospital, despite multiple interventions, including standard strategies (education, policies, feedback) and nurse-directed positive-reinforcement strategies, urinary catheter use did not decrease. Given nurse enthusiasm for the "ex-Foley-ating" campaign, it is possible that specific nurse empowerment to remove unnecessary catheters by protocol (without requiring individual physician orders) may have further reduced catheter use; yet, despite requests by infection control since February 2012, this hospital's nurses are not empowered to remove catheters.

BRIDGING THE CHASM-ADVANCED ILLNESS MANAGEMENT: HIGHER QUALITY, LOWER COST Sandy Balwan¹; Ramiro Jervis¹; Joseph Conigliaro¹; Kristofer L. Smith². North Shore LIJ Health System, Manhasset, NY. (*Tracking ID #1936650*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can delivering in-home care, to elderly patients with multiple chronic illnesses and functional impairment, focused on prompt response to changes in clinical condition and high quality transitions, result in lower total cost of care?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Leverage information technology including real time notification to Improve care coordination between hospital, physician group, and home/community services. 2) Create an on-demand program to respond to patient's changes in clinical status through same day urgent visits, 24/7 telephonic triage and off-hours community paramedicine. 3) Improve patient specific metrics (hospital length of stay, number of hospital encounters, readmissions, patient satisfaction, percent of death at home).

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The North Shore LIJ Health System Advanced Illness Management (AIM) House Calls Program is a multidisciplinary team of physicians, nurse practitioners and social workers with central support personnel including a nurse intake manager, practice manager, biller, data analyst, project manager, administrative assistant, medical coordinators, medical director, and director of quality and case management. Program eligible patients require two or more chronic conditions, a recent hospitalization or unmet symptom need, and meet Medicare definition of home boundedness. Patients must also be willing to allow AIM providers to serve as their primary care provider. Patient Characteristics: Mean age was 85 years, 72.2 % female and 27.6 % male. Most needed assistance with 5–6 ADL's (65 %). The most common diagnosis were diabetes, protein-calorie malnutrition, decubitus ulcer of the skin, congestive heart failure, cardiac arrhythmias, COPD, renal failure, stroke, vascular disease, and Parkinson's and Huntington's disease.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/

INTERVENTION): Quantitative measures to evaluate the program include hospital admission rate, 30 day readmission rate, hospital length of stay (LOS), percent of in-home post discharge medicine reconciliations performed within 48 h, percent of patients with advanced care planning and percent of patients who die at home. Qualitative metrics included American Academy of Home Physicians surveys of patient satisfaction, likelihood to recommend the program, and whether the program met patient needs.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *"FINDINGS WILL BE DISCUSSED"*):

Among the enrollees in the program, the percentage of patients who had a post-admission contact within 48 h rose from 45 % in quarter 3 of 2012, to 85 % in quarter 3 of 2013. The acuity of patients entering the program, increased over time with the average HCC diagnosis risk score increasing by 46 % by quarter 3, 2013. Mean hospital LOS decreased from Q4 in 2012 (8.61 days) to Q3 in 2013 (7.28 days). Compared to the year prior to enrollment, patient experienced a 37 % decrease in hospital admissions. Hospital 30 day readmission rate was 17 % for patients discharged to rehabilitation facilities and 12 % for patients discharged to home. Post discharge in-home medication reconciliation was performed within 48 h of discharge for 94 % of patients in quarter 3, 2013 compared to 63 % in quarter 2, 2012. Of the total patients enrolled in the program, 95 % had an advanced care plan in place. In 2013 65 % of patients were able to die at home. Patient satisfaction: When asked about likelihood to recommend the program, 84 % responded "definitely yes" in September 2013 compared to 77 % in October 2012. Seventy one percent responded "definitely yes" when asked if they were seen by the team within 36 h for urgent medical problems in 2013, compared with 63 % in 2012. When asked about receiving answers to medical questions the same day, 65 % responded "definitely yes" in 2013 compared with 45 % in 2012. Sixty five percent responded that the program reduced their trips to the ED in 2013 compared with 56 % in 2012. Eighty percent of patients felt that the program improved their quality of life in 2013 compared with 71 % in 2012.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

Implementation of a high quality advanced illness management program can decrease admission rates, hospital length of stay and increase patient satisfaction despite an increase in overall patient acuity. AIM programs can provide person-centric planning to balance curative and comfort care as disease progresses. Such programs must include an interdisciplinary team, and provide coordination of care between hospitals, physicians, home, and community services. However, the needs of the community can quickly outpace program resources. Our wait list is currently over 100 with a 3–4 month wait for non-acute referrals. Programs must also ensure buy in from senior leadership, finance and quality departments, and must leverage informatics to achieve high reliability. The employment of community paramedicine to assist with patient evaluation and triage during off hours is also critical to program success.

BRIEF CLINICIAN SURVEY CAN PRODUCE REMEDIAL FACTORS TO REDUCE CLINICIAN BURNOUT Sara Poplau¹; Scott Shimotsu²; Mark Linzer¹.

¹Hennepin County Medical Center, Minneapolis, MN; ²Hennepin County Medical Center, Minneapolis, MN; ³Hennepin County Medical Center, Minneapolis, MN. (*Tracking ID #1926205*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Clinician stress and burnout rates are high and rising across the country.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Many contributors to these conditions have been studied. We piloted a brief survey to determine areas for work life improvement within medical departments at an upper Midwestern safety net hospital.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The survey was administered by a new Provider Wellness Committee charged with improving clinician wellness throughout the institution. We developed a brief questionnaire that was distributed electronically via Survey Monkey to clinicians. The instrument was adapted from prior worklife measures from the MEMO study (Minimizing Error Maximizing Outcome). It is comprised of 10 quantitative questions concerning stress, burnout and their predictors, and one open ended question about stress. The survey was sent to all 540 inpatient and outpatient clinicians in the hospital system, including dentists, psychologists, physicians and advanced practice providers (NPs and PAs).

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/

INTERVENTION: The survey queried job satisfaction, stress, burnout, workload; time for documentation, work environment (chaotic, busy, calm), values alignment with leadership, teamwork, time spent at home using the electronic medical record (EMR), and EMR proficiency. The analysis included simple counts and frequencies of outcomes by department. We used adjusted logistic regression to evaluate factors that predicted burnout, and performed latent class analyses to determine characteristics of satisfied and dissatisfied clinicians. We hypothesized that burnout rates would vary among departments, along with the predictors.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *“FINDINGS WILL BE DISCUSSED”*): Of the 540 providers, 352 (65 %) clicked on the survey and 314 (58 %) completed it. Of the 314 providers who completed the survey, 166 (53 %) filled in the open ended question about stressors, some typing pages of commentary. Of the respondents, 59 % were female, 85 % were white, and 19 % were part-time. Fifty-four percent were physicians, and 34 % were APPs. Burnout rates ranged from 0 to 50 %. In general, most providers were satisfied with their jobs (82 %), although 60 % noted a high degree of stress. Approximately 45 % noted poor or marginal control of their workloads, 51 % had insufficient time for documentation, and 44 % spent excessive time at home using the EMR. Adjusted regression analyses showed that burnout was predicted by stress (Odds Ratio (OR) 13.8, 95 % CIs 5.3, 35.7), lack of control (OR 5.5, CIs 2.6, 11.3), values alignment (OR 0.28, CIs 0.13, 0.63) and lack of EMR proficiency (OR 3.1, CIs 1.1, 8.8). Satisfied clinicians demonstrated low burnout, high values alignment, excellent teamwork, and high EMR proficiency. These findings were presented to a 4 h Provider Wellness Committee retreat with department Wellness Champions to determine tailored interventions for wellness and lower burnout. Intervention focal areas included communication, team building, promoting work control, and minimizing EMR stress. For example, a seminar may be convened to improve providers' abilities to navigate through the EMR with "short cut" keystrokes or toggling.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): This pilot process shows it is possible to use a brief survey tool to inform an institution and address work life challenges and high burnout rates. Wellness-oriented interventions should focus on lack of control, values alignment, EMR proficiency and teamwork. The impact from wellness interventions on important outcomes such as clinician turnover and quality of care remains to be determined.

CAN E-CIGARETTE HELP PATIENTS TO REDUCE OR STOP SMOKING IN PRIMARY CARE PRACTICE? Jean-Paul Humair; Rodrigo Tango. University Hospitals of Geneva, Geneva, Switzerland. (*Tracking ID #1938888*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The evidence about the acceptability and effectiveness of the electronic cigarette (E-cigarette) to reduce or stop tobacco use in primary medical care is very limited but plausible.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): This exploratory study assessed whether the E-cigarette was acceptable for patients, helpful for a short-term reduction or cessation in tobacco smoking and defined the profile of regular E-cigarette users.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Since mid-2013, E-cigarette was offered as a new aid to smokers who attended an outpatient clinic of an urban university hospital in Switzerland. All smokers received the usual motivational and behavioral counseling. Those who wished to reduce tobacco use or failed to stop smoking with usual cessation therapy (nicotine replacement, varenicline, bupropion) were offered to use E-cigarette with nicotine.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Acceptability will be evaluated with the proportion of patients using the E-cigarette daily for several months. The effectiveness will be assessed by proportions of E-cigarette users who either reduced their tobacco consumption by at least 30 % or quit smoking completely at the end of follow-up and at 1 year. Effects of E-cigarette on withdrawal and mental symptoms, changes in expired CO measurements, patient satisfaction and adverse events must also be measured.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *“FINDINGS WILL BE DISCUSSED”*): Seventeen patients chose to use the E-cigarette. They were heavy and dependent smokers consuming a daily average of 23 cigarettes and smoking their first cigarette 16 min after waking up. A somatic tobacco-related illness (65 %) and a mental disorder (82 %) were very common in this sample. All patients but one used the E-cigarette daily either to reduce their tobacco use (59 %) or to quit

smoking (41 %). Most patients (88 %) changed their behavior positively with either tobacco reduction or cessation during an average follow-up of 3 months. Half of patients (47 %) decreased their mean cigarette consumption by 57 %; the reduction was lower than 30 % for a single patient using E-cigarette without nicotine. A similar proportion (41 %) reported to have achieved tobacco abstinence. Pharmaceutical nicotine replacement or varenicline were used at some stage by 59 % of patients in association with the E-cigarette. Patients reported no significant side effects but were often unclear about their nicotine intake and levels of nicotine in E-liquid cartridges.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): E-cigarette with nicotine is well accepted and used daily by most patients willing to reduce consumption or to quit smoking after failed attempts. Short-term results in this very small sample suggest that E-cigarette might be effective to help smokers attending in primary care to reduce or stop tobacco use. Clinicians may start offering to some smokers the E-cigarette, which enlarges the choice of smoking cessation aids. As stronger evidence is needed, clinical trials with larger samples should test the effectiveness of E-cigarette to change smoking behavior and maintain it in the long-term among patients in primary care practice.

CAN PHYSICIAN REVIEW OF READMISSIONS IMPACT PROVIDER PERCEPTIONS AND REDUCE READMISSION RATES? Edmund A. Liles¹; Carlton R. Moore¹; Beth Ann Brubaker¹; Jonathan Kirsch¹; Paul Ossman¹; Monica Reynolds¹; Jacob Stein²; John M. French¹. ¹University of North Carolina School of Medicine, Chapel Hill, NC; ²University of North Carolina School of Public Health, Chapel Hill, NC. (*Tracking ID #1938216*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): If hospitalist physicians perform chart reviews and root-cause analyses on their readmitted patients, will it change their perceptions of the causes and preventability of readmissions, and reduce overall readmission rates?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Hospitalist physicians conduct chart reviews and root-cause analyses on all of their patients readmitted within 30-days of hospital discharge 2. Assess impact on hospitalist physician perception of cause and preventability of readmissions 3. Assess impact on 30-day all-cause readmission rate

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We present a before-after (uncontrolled) trial evaluating timely feedback of readmissions to hospitalist physicians. As a part of routine patient tracking, the quality improvement department of UNC Hospitals creates a daily list of patients who are currently registered as receiving care within UNC Hospitals (inpatient, observation, procedure or emergency department). For this study, that list is filtered to include only those patients who were an inpatient within the last 30 days and cared for by a faculty member from the Hospital Medicine Program. Patients are removed from the list if they have planned readmissions (UNC Psychiatry or Rehabilitation on the same day, or return to the North Carolina Cancer Hospital for planned chemotherapy). The hospitalist physician for the index admission is notified on the day of a readmission. The hospitalist physician is responsible for performing a chart review and root-cause analysis on the readmission. The chart review and root-cause analysis is a structured tool adapted from the Institute for Healthcare Improvement STAAR Initiative.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The primary measure of success is a reduction in the 30-day readmission rate. We also assessed physician perceptions regarding the causes of readmissions and estimates of preventability, both before and after the intervention. Since a reduction in readmissions may be a result of physicians keeping patients in the hospital longer, we also collected data on length of stay during the study period. The notifications and chart reviews began July 1, 2013 and are ongoing. Descriptive statistics are presented. Continuous variables are analyzed via *t*-test for means and chi-squared for proportions. A Shewhart P chart is used to describe 30 day readmission rates over the course of the study.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *“FINDINGS WILL BE DISCUSSED”*): 30 day all cause readmission data is currently available through the end of October 2013. For the 18 months prior to the intervention our 30 day all cause readmission rate was 12 %, since starting our intervention the rate has decreased to 10 % (chi-squared, *p*=.18). The Shewhart P chart for 30-day readmissions shows a possible trend toward reduced readmissions since the start of the intervention in month 19. Average length of stay increased from 4.73 days over the prior 18 months to 5.01 for the

4 months since the intervention (*t*-test, $p=0.1$). At baseline the top three contributors to readmissions were felt to be patient understanding, medication non adherence, and substance abuse/addiction. After 6 months of the intervention, the top three contributors were felt to be substance abuse/addiction, medication non adherence and lack of primary care. Based on the STAAR tool chart review, the index hospitalization and readmission had the same diagnosis in 50 % of cases. Thirty percent of the readmissions were labelled preventable. The two most common categories contributing to readmission were problems with adequate follow up and medication errors or complexity.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our intervention of readmission notification and chart review has resulted in a downward trend in readmission rates without significant changes in length of stay. The initial results are promising and our data collection and analysis is ongoing. Physicians continue to feel the majority of readmissions are not preventable. Chart review and physician perception indicate follow up and medication adherence are major concerns. Our faculty group continues to discuss our readmission rates during monthly faculty meetings and we have formed a complex care committee to develop individualized care plans for our highest needs patients.

DEVELOPING A GERIATRICS CONSULT CLINIC IN THE SAFETY NET

Anna H. Chodos¹; Christine Ritchie^{1,2}; Janet Myers²; Hali Hammer³; Edgar Pierluissi¹. ¹UCSF, San Francisco, CA; ²UCSF, San Francisco, CA; ³UCSF, San Francisco, CA. (Tracking ID #1938100)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The health care safety net provides primary care to medically and socially complex older adults, but there are rarely geriatrics specialists available in this setting.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): A. Create an outpatient geriatrics consult service in the San Francisco Department of Public Health's (SFDPH) safety net healthcare system using eReferral, an existing electronic health care record (EHR) referral mechanism. EReferral allows for iterative conversation between primary care providers (PCPs) and specialists, and allows efficient communication of recommendations and scheduling. B. Measure the proportion of geriatrics referrals that were managed through: 1) electronic advice (e-advice), or 2) e-advice and co-management (eg. direct social work referral, call patients or caregivers) without seeing the patient, or 3) comprehensive geriatrics assessment (CGA) of the patient in an outpatient setting. C. Measure consult's impact on PCP satisfaction and PCP's feelings of self-efficacy in geriatrics.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In October 2012, we began a geriatrics outpatient consult service for 2 SFDPH primary care clinics, for patients age 65 or older. We accept consults via eReferral, and the staff of 1 geriatrics fellow and 1 attending meet twice weekly to review consult questions and accompanying patient records, and triage to 1, 2, or 3 as listed above. We have a once monthly half-day clinic for CGA and do home visits as needed.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We measured the number of consults received, time spent for consults, and nature of referral questions. We used surveys to assess providers' satisfaction and self-efficacy with geriatric conditions after the consult.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): Over 54 weeks, PCPs referred 100 patients to the geriatrics consult service and 2 geriatrics providers each spent an average of 77 min (median 60 min) weekly reviewing and responding to them. Of the 100 patients referred, 20 were managed with e-advice only, 17 were managed with e-advice and time-limited co-management, and 63 were seen in the clinic. Most consults (68 %) listed >1 reason for referral and 21 % asked for CGA or management of medical complexity. Common consult questions were cognitive impairment (60 %), social issues (27 %), medication review (26 %), and falls (19 %). For the 63 patients seen (in 13 clinic sessions and 11 home visits), each visit took an average of 2.1 h per patient. Provider surveys (response rate 65.9 %) showed 94.9 % would use it again, 78.3 % strongly agreed that their question was addressed to a satisfactory level, and 97.3 % felt their geriatrics knowledge improved.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A Geriatrics consult clinic can provide effective support to PCPs in the safety net setting without seeing every patient. The most frequent reasons for referral were

cognitive impairment, medical complexity and social issues. Providers felt the service was useful, including for patients seen with e-advice only. The next steps are to examine: 1) the nature of consult questions dealt with via e-advice vs. CGA, 2) the interventions of the geriatrics consult clinic, 3) patient outcomes before and after geriatrics consult, eg. number of inappropriate medications as determined by Beers criteria; health care utilization; documentation of advance care planning, and 4) identify ways to improve specialists' time-efficiency, particularly with CGAs.

DEVELOPMENT AND IMPLEMENTATION OF AN ELECTRONIC REGISTRY TO SUPPORT ADHERENCE TO OPIOID PRESCRIPTION GUIDELINES AMONG ADULT PRIMARY CARE PROVIDERS Christopher W. Shanahan¹; Donna Beers¹; Vinay Hoolloemann³; Karen E. Lasser¹; Jane M. Liebschutz^{1,2}. ¹Boston University School of Medicine, Boston, MA; ²Boston University School of Public Health, Boston, MA; ³VINK Software Technologies Inc., Acton, MA. (Tracking ID #1937571)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): To design, develop and implement an electronic registry for use in primary care by a nurse case manager to improve care of patients being treated with opioid medications for chronic pain.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Develop, implement, and test an electronic registry of patients with chronic non-cancer pain being treated with long-term opioid medications for use by a dedicated Nurse Case Manager (NCM), with a goal of maximizing efficiency and safety while minimizing risk of addiction and diversion. 2. Ensure that the electronic registry is intuitive, user-friendly, and closely supports the NCM's actual workflow. 3. Develop, implement, and test tailored reports for use by the NCM, the project investigators, and specific primary care providers for use within an academic detailing session to improve provider performance and adherence to chronic pain management and opioid prescribing care guidelines (American Pain Society - American Academy of Pain Medicine).

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The electronic registry was developed to support evidence-based case management within a cluster randomized control trial comparing adherence to guideline based care of patients treated for chronic pain with opioids in primary care based practices (internal medicine and family medicine) in an urban safety net hospital and three community health centers in Boston. Primary care physicians (PCP) will be randomized to one of two conditions: intervention (nurse care management, registry, electronic decision support tools, and academic detailing) or control condition (electronic decision support tools only). Chronic pain patients (560) and PCPs (56), both control and intervention, will be followed for 12 months after study enrollment to assess the primary outcomes of rates of PCP adherence to chronic opioid therapy guidelines and opioid misuse among patients. The intervention group will receive intensive practice support from the NCM, who has access to the electronic health record and a state-of-the-art electronic registry tool designed and built by the study's technology team. The registry provides a dynamic, filterable work list which is clickable and linked web-based forms to facilitate various clinical encounters including: medication refills, risk assessment, clinical assessment, and treatment plan creation, along with flexible reporting which provides both practice and provider specific monitoring for care management and academic detailing.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The following specific aims will serve as measures of this study's success: 1) Evaluate the relative effectiveness of the intervention compared to the control condition on rates of PCP adherence to chronic opioid therapy guidelines. 2) Evaluate the relative effectiveness of the intervention compared to the control condition on rates of clinically significant reduction in opioid misuse by patients. 3) Develop a road-map for widespread dissemination of the implementation strategy, through qualitative assessments and a cost analysis.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): 1. Development of a computer application to support actual clinical workflow for programmatic interventions that is simultaneously being developed in terms of staffing and workflow is feasible but complicated. 2. Design and development of efficient workflow enhancing technology is labor intensive and requires rapid design and development cycles. 3. Theoretic design work is critical but only provides the starting point for the full understanding of the workflow of a new clinical process. Flexibility and iterative open dialogue combined with sufficient time to develop, test, and revise is critical. 4. Screen shots of developed key components of the functional registry, an integrated workflow/application diagram will be presented.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Development of an advanced, automated case-management registry, must be grounded in actual clinical practices and processes. Success of the development process is critically dependent on a trusting and bidirectional partnership between clinical users and application developers based on mutual respect and a shared goal of creating the most clinically effective application possible.

DIABETIC GROUP VISITS: A "REAL WORLD" PILOT PROGRAM Marshall Fleurant¹; Megan Bergstrom^{3,1}; Bonnie Burke⁴; Gertha Dabady¹; Karen Chalmers²; James Rosenzweig²; Karen E. Lasser¹. ¹Boston University School of Medicine, Boston, MA; ²Boston University School of Medicine, Boston, MA; ³Boston Medical Center, Boston, MA; ⁴Boston Medical Center, Boston, MA. (*Tracking ID #1934535*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can we utilize a series of diabetic group visits to improve self efficacy for patients with diabetes, maintain patients' access, complete diabetic processes of care and achieve improved hemoglobin AIC (HbA1c) control?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1.) Evaluate the feasibility of the diabetic group visit series as a mechanism to treat patients with diabetes within a large urban safety-net patient centered medical home 2.) Evaluate patient health beliefs before and after group visits 3.) Maintain or improve HbA1c levels over the course of the group visit series

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This program consists of four group visits and a set curriculum occurring over 3 months. Every 3 weeks patients meet, these visits are designed to increase patient self-efficacy and improve HbA1c levels. The curriculum encompassed the pathophysiology of diabetes, medication use and safety, diabetic nutrition and weight loss, and helpful resources to help treat your diabetes. Each visit is 2 h long and facilitated by a multidisciplinary team. The visit begins with a lecture followed by an interactive session led by a nurse practitioner to reinforce lessons learned and allow patients to share experiences. During interactive sessions, patients leave the group for individual medical consultations with a provider. A pharmacist or nutritionist may lead interactive sessions during the second hour. Our experience includes both a spring and fall series with eight group visits in total.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We measured patients' attendance, HbA1c levels before and after the series, and measured health care utilization including outpatient and emergency department visits as well as hospitalizations. We also collected data on process measures such as testing for HbA1c, urine microalbumin, and low-density lipoproteins (LDL). We assessed patient health beliefs using a previously validated "Diabetes Related Health Beliefs" survey.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *â€œFINDINGS WILL BE DISCUSSEDâ€*): We invited two primary care providers (PCP's) patients ($n=167$) who were identified as diabetics by the electronic medical record problem list. In total 20 patients participated. Approximately 13 patients attended the four visit spring series and 8 attended the four visit fall series. One patient attended both series. We measured HbA1c 6 months after the completion of the spring series; 10 of 13 patients experienced declines in HgA1c from baseline. The average decrease in HbA1c was 0.52 % (Standard Deviation, 1.75 %). In the year prior to group visits, only 10 of the 20 participants saw the same PCP continuously (defined as at least 50 % of all PCP visits were with the same provider). However during the group visits 16 of the 20 participants saw the same PCP continuously and 10 of 20 patients went to group visits solely for their primary care needs. Group visits appeared most effective in capturing process measures for patients that were infrequent utilizers of care. Exactly 82 process measures were completed in the 6 months before and after the first group visit. Approximately 20 % of all labs were processed during the group visits. Among patients whom attended 10 or less total outpatient visits in the year, 40 % of process measures were processed during group visits vs only 5 % for patients who attended greater than 10 total outpatient visits per year. Group visits seem to affect participants perceptions on the role of medication in the care of diabetes but not the role of diet. Prior to the group visit series, 43 % who completed the survey ($n=7$) were confused by all the medications given to them by their doctor, after the group visit series 17 % ($n=6$) endorsed this belief. However approximately 57 % agreed that medications would control diabetes before the group visit series vs 33 % after the group visit series. Patient's beliefs regarding the role of diet in the control of diabetes did not change. For example over 70 % of patients before and after the group visit series believed that diet could help control complications related to diabetes or that they should continue to follow their diabetic diet even if they did not feel better.

Approximately 50 % of patients before and after the group visit series felt that their diabetes was well controlled.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

Among a selected group of patients who participate, group visits can improve continuity within primary care and improve HbA1c. Group visits may also play a role in meeting recommended process measures for a selected subset of patients. Strongly held beliefs prior to group visits may be difficult to alter, patient's self perception on medications or diet are important factors to consider when designing a program.

DIABETIC RETINOPATHY IS COMMON AMONG PATIENTS SEEKING CARE FOR DIABETES IN A COMMUNITY HEALTH CLINIC Carolyn F. Pedley¹; Claudia L. Campos¹; Emily W. Gower²; Daniel Nelson²; David Friedman⁴; Ramon Velez¹. ¹Wake Forest School of Medicine, Winston-Salem, NC; ²Wake Forest School of Medicine, Winston-Salem, NC; ³Wake Forest School of Medicine, Winston-Salem, NC; ⁴Johns Hopkins School of Medicine, Baltimore, MD. (*Tracking ID #1939136*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): What is the incidence of diabetic retinopathy identified by high resolution retinal photography in a community health clinic?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To screen diabetic patients in a community-based adult medicine clinic using a high resolution non-mydriatic retinal camera. To evaluate retinal images for diabetic retinopathy and other ocular pathology To calculate the incidence of diabetic retinopathy in this underserved population

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The Downtown Health Plaza is a safety net university-affiliated outpatient clinic that provides health care for approximately 1,700 adults with diabetes. The majority of patients are uninsured or are covered by Medicaid. The clinic serves as a training site for medical residents supervised by eight faculty physicians. The retinal camera, computer, software and study protocol were provided by a research grant awarded to the Johns Hopkins research group with funds from the Centers for Disease Control. Retinal photographs were read at the Wills Eye Center in Philadelphia, PA and participants were referred to the Wake Forest Eye Center or their preferred ophthalmologists for further management as needed

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The success of the program was measured by the number of diabetics screened and the photographs having sufficient quality to identify retinal pathology. Follow up appointments with Ophthalmology for those with significant retinopathy also were tracked.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *â€œFINDINGS WILL BE DISCUSSEDâ€*): 180 participants were screened over a 6 month period. Participants' ages ranged from 19 to 91 and 67 % ($n=120$) were female. We were unable to obtain photographs for 1 individual due to difficulty positioning her in front of the camera. An additional 13 % of photographs could not be read due to poor image quality or inability to view the retina because of corneal or lens opacity. Among the remaining 156 participants, 29 %($n=46$) had abnormal retinal findings requiring referral to an ophthalmologist, with 17 requiring urgent follow up due to severe diabetic retinopathy. Only 26 % reported seeing an eye doctor in the last year and less than 50 % had seen an eye doctor in the last 2 years.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A significant number of screened participants had retinopathy requiring further management by ophthalmology. Given the low rate of eye care utilization in this population and the success of this program in screening participants, the use of camera screening for diabetic retinopathy in primary care should be considered on a broad scale. Such programs would increase diabetic retinopathy awareness in these populations. Challenges: There is considerable expense in purchasing the camera, software, reading, data tracking and personnel in implementing a screening program utilizing retinal photography. The tracking of participants involves sharing information across several settings including the clinic, the reading center, patients, providers, and the ophthalmology group.

EMBRACING THE HUDDLE IN A RESIDENT TEACHING CLINIC Edward Ewen; Sarah Schenck; John Donnelly. Christiana Care Health System, Newark, DE. (*Tracking ID #1938872*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Despite ongoing efforts to improve the consistency and quality of care delivered in our resident teaching clinic our performance had stalled after modest improvement in several measures, in part due to unrecognized or missed opportunities to affect care during the course of scheduled patient visits.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): A pre-session huddle each day to: 1) Identify opportunities for improvement immediately prior to the patient visit 2) Improve the overall consistency and quality of care delivery 3) Optimize Systems Based Practice in the setting of a Patient Centered Medical Home by more fully integrating the medical assistants into the resident-patient office workflow

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A Huddle is an informal meeting between a provider and medical assistant to discuss, anticipate and prepare for the needs of the patients in an upcoming clinical session. In order to successfully role out the patient care Huddle, we started with physician and staff education. A presentation was given to all of the providers as part of the Preclinical Pearls teaching curriculum. The staff was also given education about the importance of the Huddle. To standardize the information that was shared during the Huddle, a form specifically designed for this purpose was completed by the residents and discussed with the Medical Assistant before the morning session. To ensure the completion of the Huddle, a 15 min block of time was incorporated into the schedule every morning. Faculty preceptors were assigned the responsibility of making certain the Huddle was completed each day. The Huddle was initiated in July 2011.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Since the Huddle emphasized preventative health care and chronic disease management, we focused on two aspects of care that could be directly impacted and facilitated by a pre-visit huddle; annual foot exams in diabetic patients and pneumonia vaccination in patients 65 years and older. To measure the success of our intervention we surveyed the residents on their impressions of the Huddle immediately prior to and 1 year after initiating the Huddle. We also analyzed pre and post intervention completion of annual diabetic foot exams and pneumonia immunization using a simple 2-rate chi-square test and a segmented Poisson regression to compare rates and trends 3 years prior to and 2 years following the intervention.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): The Huddle was well-received by residents who indicated improvement in both communication with staff and efficiency in care delivery in 4 of 5 items surveyed. For 2 years prior to the intervention residents were receiving regular feedback on their diabetic foot exam performance, however, pneumonia vaccination reporting was started 1 year after Huddle initiation. The rate of annual foot exams increased from 42.5 % before to 63.8 % after intervention ($p < 0.001$) with a significant increase in the rate of improvement from 0.28 to 0.63 % per month ($p = 0.001$). Pneumonia vaccination rates initially fell in the first year following the Huddle from 60.1 to 58.3 % ($p = 0.5$), however, once performance feedback was provided to the residents the rate climbed from 58.3 to 70.4 % ($p < 0.001$) and was accompanied by a significant increase in the rate of change from 0.01 to 0.5 % per month ($p < 0.001$).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The Huddle, when combined with provider-specific performance feedback, can lead to significant improvements in the quality and consistency of care delivered in a resident teaching clinic. In our experience, a planned roll-out with education for both physicians and staff was needed before starting the Huddle process. The development of a Huddle checklist/form provided greater process uniformity and efficiency. In addition, protected time in the schedule for the Huddle to take place was essential for successful integration into the office workflow.

ENHANCING APPROPRIATE USE OF CARDIAC TELEMETRY TO IMPROVE CARE AND REDUCE WASTE Daniel Henderson; Christopher Kelly; Deepa Kumaraiah. Columbia University Medical Center, New York, NY. (Tracking ID #1934836)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Is a quality improvement effort to limit overuse of continuous electrocardiographic monitoring in general medical inpatients associated with improved rates of appropriate use?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): I. To define clinical guidelines for the use of cardiac telemetry for general medical ward patients, a population for whom no such guidelines exist, in a large, urban, academic medical center. II. To redesign the process of ordering cardiac telemetry around such guidelines, with oversight of extended use of telemetry, in order to curtail overuse. III. To evaluate the redesigned ordering process for effects on use and overuse of cardiac telemetry.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In 2013, our hospital, a 710-bed academic general hospital member of a 1600-bed academic medical center, faced unprecedented demands in the wake of a recent natural disaster and temporary closure of several major hospitals. In this context, our institution identified continuous cardiac telemetry as a source of delayed care and waste of resources. We redesigned the process of telemetry ordering to promote appropriate use and minimize resource constraints. Cardiac telemetry, once found only in coronary care units (CCUs), is now widespread in nearly all units of most hospitals, despite limited or absent clinical evidence for its utility beyond a limited set of cardiac conditions. A handful of studies have loosely linked telemetry with bottlenecks to patient flow, particularly emergency department (ED) waiting, and with adverse clinical outcomes as a result. In fall 2013, we redesigned our telemetry ordering process to curtail inappropriate use and relieve system pressures due to overuse. Through a systematic literature review, we identified a limited evidence base for telemetry use, especially in patients without major cardiac problems, where guidelines are sparse. We developed a list of conditions for which telemetry was clearly or probably indicated, with thresholds for discontinuation. We also created a set of conditions where telemetry was commonly ordered, but clearly not indicated. This information was disseminated and incorporated into order-entry functions of the electronic health record system for timely availability at the point of care. This presentation details our evaluation of telemetry orders in one-month periods before and after implementation to assess the appropriateness of orders, within the ongoing evaluation of the project's effectiveness in curtailing telemetry overuse and its sequelae.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We measured the proportion of appropriate orders, per the new guidelines. Appropriate orders had one clear indications, and inappropriate orders, clearly non-indicated ones, as assessed by order free text data and focused chart review. Benefit of the doubt was assumed, and cases where a determination could not be made were counted as indeterminate. The goal was a 33 % or greater reduction in inappropriate use between study periods.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE "FINDINGS WILL BE DISCUSSED"): We will present our institutional guidelines for telemetry in general medicine ward patients, as well as the analysis of the improvement project. Initial evaluation of 100 randomly-selected patient telemetry orders from both study periods revealed 46 % inappropriate orders in the pre-intervention period, and 32 % in the post-intervention period, a 30.4 % reduction, and a statistically significant effect at the 5 % level by the chi-squared test. Indeterminate orders made up 12–18 percent of reviewed entries. These initial results show a significant effect, just below the specified goal of the measure. To ensure 80 % power for a 20 % effect, further analysis of 500 patients will be presented in the final results, along with stratified analyses to assess for confounding due to differential ordering practices by provider and service types.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Telemetry is frequently overused, and this overuse is responsive to a simple intervention to improve practice. Guidelines for the appropriate use of telemetry can be developed to guide its use where a dearth of evidence exists, significantly improving appropriateness. Clinicians respond to informational interventions at the point of care.

FACTORS CONTRIBUTING TO READMISSIONS FOR PATIENTS WITH ISCHEMIC HEART DISEASE Vishal Patel; William S. Weintraub; Roger Kerzner; Edmondo Robinson; Tabassum Salam; Daniel J. Elliott. Christiana Care Health System, Newark, DE. (Tracking ID #1934521)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Despite intense scrutiny on the need to reduce readmissions, surprisingly little is known about the factors which lead to readmissions. Understanding these factors could help more appropriately target interventions to improve care transitions.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): We performed a thorough case review of all patients with ischemic heart disease readmitted within 30 days of discharge from percutaneous coronary intervention (PCI) or coronary artery bypass grafting (CABG). We sought to identify factors leading to readmission, determine preventability, and implement real time interventions to circumvent these readmissions.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Structured case review of all adult inpatients at a single tertiary care institution discharged from May 2013 to date with an index visit that included ischemic heart disease with revascularization who were readmitted within 30 days of discharge. All patients were enrolled in an integrative and innovative care management program prior to index discharge and consented for this review. Case review involved chart audits, interviews with re-admitting physicians, patients, and overall case adjudication by a physician team using a standard tool.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Demographic information and patient characteristics were collected to determine its relation to preventability. Data on preventability, location where efforts to prevent revisit could have been targeted factors for readmission, and role for care management to further engage the patient were also collected.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): Forty-five patients had an unplanned 30 day readmission. Forty-seven percent (21) of the readmissions were assessed as potentially preventable; 11 % were very likely to be preventable and 36 % were likely to be preventable. Of the preventable readmissions, 48 % (10) could have been prevented prior to index discharge and 33 % (7) could have been prevented at home or nursing home. There was role for case management to further influence patient's care in 95 % of the preventable cases. During discharge process, patients were, on average, started on 7 new medications from admission and issues related to medication reconciliation were seen in 15 % of the cases. The major factor during discharge process was not having a follow up appointment scheduled within 2 weeks of discharge (40 %). Major issues for home and outpatient care included inadequate services provided by home health services or nursing home (25 %), difficulty to manage symptoms at home (22 %), and poor communication with patients (28 %). In terms of hospital readmission, 70 % of all patients were readmitted for cardiac causes.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): This study has identified key factors for readmission and has shown that case management has a crucial role in preventing these events. Issues around communication and fostering partnership can help improve care transitions. Implementation of a multi-disciplinary group will help to customize targeted interventions with emphasis on the discharge process from index visit and management of post-acute care cardiac symptoms at home.

FEASIBILITY OF DIABETIC RETINOPATHY SCREENING USING A NON MYDRIATIC CAMERA IN A COMMUNITY HEALTH CLINIC Claudia L. Campos¹; Carolyn F. Pedley¹; David Friedman²; Emily W. Gower^{4,3}; Daniel Nelson³; James L. Wofford¹; Ramon Velez¹. ¹Wake Forest University, Winston-Salem, NC; ²Wilmer Eye Institute-Johns Hopkins School of Medicine, Baltimore, MD; ³Wake Forest University, Winston - Salem, NC; ⁴Wake Forest University, Winston Salem, NC. (*Tracking ID #1938696*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Is routine screening of diabetic retinopathy with a non mydriatic camera feasible in the primary care setting?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): – To perform routine retinopathy screening using a high resolution retinal imaging camera on all diabetic patients that present for regular clinic visits in the Adult Medicine Clinic - To train clinic personnel to operate a non mydriatic camera and upload photographs for remote grading - To determine patients' self-report experiences with the screening process and elicit patients' input for improving the screening process

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Located in Winston-Salem, North Carolina, USA, the Downtown Health Plaza Adult Medicine Clinic is affiliated with Wake Forest Medical Center, involves resident training and serves as a safety net for the community. It typically logs more than 25,000 adult clinic visits each year and serves a large number of Medicaid and uninsured patients. Three physician assistants, eight faculty and 40 resident physicians have clinic sessions 1–3 times a week with the

support of 9 nursing staff (2 CMAs, 6 LPNs and 3 RNs). Diabetic participants were offered retinal photography as they came to clinic for regular appointments. Photographs were performed at the time of the appointment and a small number (34/180) were given appointments for photographs at a later date -Personnel training: Designated nursing staff received training to operate the camera and upload pictures on the computer system; 3 LPNs completed an -in person- four hour training course. A research assistant was also trained to take photographs when the nurses were unavailable or too busy. -Patient recruitment and intervention: during patient rooming, nurses recommended retinopathy screening to all diabetics presenting for a clinic visit. Immediately after the clinic visit (or before when the providers were running behind), the patients were consented and fundus photography was performed in a private darkened room. At the beginning of the program, we attempted scheduling of participants to return for photographs at a separate time point. Midway through the program nursing personnel changes made it difficult for the nurses to have the time to consent the patients, enter data into the computer and to take the photographs. After that point, a designated research assistant performed most of these activities. The nurses continued to control patient flow. - Uploading of Images: nurses and coordinator uploaded the images to the Wills Eye Telemedicine Center. Prior to upload they were able to review images and share them with the clinicians. - Post review follow up, referral, and patient satisfaction survey: Participants were contacted by phone with their results and referred for appropriate follow up care. A copy of the findings was also sent to their primary care provider. A post- screening questionnaire was conducted 2–3 months after screening.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Number of participants screened on a weekly basis

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): Prior to designating a full-time research assistant to helping, 1–2 participants were screened per day for 2 days each week. After employing the research assistant, screenings were performed nearly every day, and the number screened per day more than doubled, averaging 4 per day, 5 days per week. On busy clinic days, 8–10 participants were screened when the research assistant was present. 61/180(34 %) retinal screenings were scheduled for a later appointment date. Of 61 scheduled visits, participants only kept 34 (55 %).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A program of screening retinal photography can be implemented in a busy clinic practice. With limited clinical resources and the time required to perform and track the photographs, there must be dedicated personnel to perform these duties. Timing of the test during clinic visits is a more effective system to serve our low income patients. Nurses were a vital component in recruiting patients and maintaining the flow of participants.

GETTING HIP TO VITAMIN D: A HOSPITALIST PROJECT FOR IMPROVING THE ASSESSMENT AND TREATMENT OF VITAMIN D DEFICIENCY IN ELDERLY PATIENTS WITH HIP FRACTURE John Stephens¹; Christine Williams¹; Eric Edwards¹; Darren A. DeWal²; Paul Ossman¹; Edmund A. Liles¹. ¹UNC Hospitals, Chapel Hill, NC; ²UNC Hospitals, Chapel Hill, NC. (*Tracking ID #1927582*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Our hospitalist group, which co-manages all patients with hip fracture at our institution, had no standardized approach for the assessment and treatment of vitamin D deficiency in patients with fragility fractures, despite Endocrine Society recommendation for screening this population and prior studies demonstrating high prevalence of deficiency.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To standardize and improve our group practice for the assessment and treatment of vitamin D deficiency in elderly patients with hip fracture. To measure the prevalence of vitamin D deficiency in elderly patients with low trauma hip fracture at our institution.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We reviewed medical evidence, including major practice guidelines, for screening for vitamin D deficiency in elderly patients with low-trauma hip fracture and assessed our group's adherence to best practice. Review of all hip fracture patients cared for by our group from June 2010 through October 2012 revealed that only 38 % had been assessed for vitamin D deficiency. Of those patients who had a level checked, 61 % were found to be vitamin D deficient using a cutoff of <30 ng/mL. Of those deficient, only 39 % were treated with the appropriate dose of vitamin D. Our conclusion was that group performance on this issue was varied and substandard. In October 2012, we created an intervention to address these findings. We presented a review of evidence and data from our practice to the hospitalist group. Concurrently, we altered the hip fracture order set in the hospital

computerized physician order entry system to include prechecked boxes for measurement of vitamin D level at admission and empiric supplementation with 1000 international units of vitamin D.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We studied implementation of the new order set by searching the hospital database for patients with ICD-9 codes for femoral neck fracture linked with discharge physicians in our group. Outcome measures included the percentage of patients screened for vitamin D deficiency and percentage of deficient patients discharged on the correct dose of vitamin D, both before and after intervention. We also described the prevalence of vitamin D deficiency in this population.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): Following our intervention, 95 % of hip fracture patients were checked for vitamin D deficiency, compared with 38 % before intervention. The proportion of patients with vitamin D deficiency who were discharged on the correct dose of vitamin D also improved, rising from 39 % before to 67 % after intervention. The prevalence of vitamin D deficiency was 49.5 %.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The prevalence of vitamin D deficiency in elderly hip fracture patients at our institution is high. Our hospitalist group practice performance in screening for vitamin D deficiency in this population was varied and not in adherence with current practice guidelines. With a review of best evidence and alteration of the hip fracture computerized physician order entry order set, we successfully standardized group practice and improved adherence to practice guidelines.

IMPLEMENTATION OF A RESIDENT HOSPITAL DISCHARGE CLINIC AT AN URBAN ACADEMIC MEDICAL CENTER Maria Hamm de Miguel; Amanda Ramsdell; Steven Shea; Nancy Chang; Luis M. Ducasse. Columbia University, New York, NY. (*Tracking ID #193847*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Hospital discharge is a vulnerable time for patients, prone to adverse events which may be mitigated by rapid follow up (<2 weeks) in a patient centered medical home setting within the same institution.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To provide timely follow-up to medicine patients within a resident PCMH in order to reduce ER visits and hospital readmissions 2. To improve the quality of the discharge process through continuity and communication between inpatient and outpatient 3. To educate residents on the importance of transitions of care

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Patients discharged from medicine teams at New York Presbyterian Hospital - Columbia University Medical Center, with participating Medicaid/Medicare plans or uninsured are given rapid follow up with a designated PGY2 (<2 weeks) in the resident continuity clinic on campus. The community served is diverse but primarily Hispanic, of low socioeconomic background, and with multiple co-morbidities. At the appointment, patients are assessed clinically and functionally, medication reconciliation is completed, new labs and tests are planned as needed, and continuity appointments are made or confirmed.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. 30-day ER visits and hospital readmission rate [Data pending] 2. Quality metrics on the discharge process and post-discharge period: a. Quality of the discharge summary b. Medication reconciliation c. Interim events d. Interventions required at discharge clinic appointment e. Hospitalist vs. resident team comparison 3. Resident survey of educational benefit [Data pending]

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): 423 patients were scheduled from 6/17/13 to 11/4/13, and 228 patients came. The high no show rate (46 %) is a critical finding that requires further investigation. Quality metrics are available for 147 patients, a 64 % completion rate. Discharge summaries were submitted for 90 % of patients. Ninety-three percent included relevant hospital events, 86 % an updated discharge medication list, 61 % PMD follow-up, and 66 % pending labs/test when required. At the visit, 27 % had incorrect medications, 16 % had difficulty obtaining new medications, 26 % were not taking medication as prescribed, and 12 % had new side effects. Patients reported new or persistent symptoms 42 % of the time. Only 1-6 % of patients had adverse events including falls, ER visits, or new limitations in mobility or functional status. Medications were adjusted in 41 %, lab follow-up in 31 %, social work referral in 12 %, and referral to the ED in 2.8 %. Forty-three percent required new primary care appointments, and 26 % required specialist. Comparing quality metrics for resident and hospitalist teams using a

chi-squared analysis (power >80 % for alpha=0.05) the majority of variables did not show a significant difference. Residents were more likely to complete discharge summaries (OR=4.5, 95 % CI 1.5–13.8, $p=0.05$) but were more likely to require a PMD or specialist visit to be made (PMD: OR 0.5, CI 0.2–0.98, $p=0.04$, specialist: OR 0.4, CI 0.2–0.8, $p=0.02$).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The implementation of a discharge clinic has highlighted how vulnerable the post-discharge time is, and identified multiple areas for process improvement. The rate of interim adverse events is low (1–6 %), but the potential for new events is high, due to persistent conditions, need for lab follow up, medication errors, and lack of adequate follow up planning. We found few differences between resident and hospitalist team patients. The challenges are a high no-show rate, a moderate completion rate of quality metrics, inadequate quality of discharge summaries, and inadequate continuity planning. These deficiencies indicate areas for further investigation and improvement.

IMPLEMENTATION OF A SCREENING PROGRAM TO ADDRESS UNHEALTHY ALCOHOL USE IN AN ACADEMIC GENERAL INTERNAL MEDICINE CLINIC Emily K. Sturkie; Daniel E. Jonas; Carol Golin; Catherine Grodensky; Jennifer Kinley; Shana Ratner; Thomas M. Miller. University of North Carolina, Chapel Hill, NC. (*Tracking ID #1936705*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Unhealthy alcohol use is common, but usually goes undetected and unaddressed in primary care

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To uniformly screen all patients in clinic for unhealthy alcohol use 2. To identify patients who would benefit from a primary care based harm reduction intervention 3. To use motivational interviewing techniques to counsel patients with unhealthy drinking and to provide appropriate referral resources for patients with alcohol use disorders

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The University of North Carolina Internal Medicine Clinic is an academic practice serving approximately 12,000 patients. The clinic uses a visit planner to prompt clerks, nurses, and doctors to perform disease management and health maintenance interventions. Utilizing this planner, we introduced a program to screen and counsel patients for unhealthy drinking. We developed educational materials and conducted a half-day workshop in motivational interviewing and intervention protocol for teaching faculty. We produced a guide to lead providers through a motivational interviewing-based intervention for risky drinkers and a separate, parallel pamphlet for patients that included educational materials and a log to track consumption. To train housestaff, we developed curricula for two pre-clinic conferences. To screen patients, nurses are annually prompted to ask patients if they drink alcohol. Those responding affirmatively answer a second question about the number of times in a year they drink > four drinks (> five for men under 65). Nurses ask those with positive responses to complete the AUDIT to identify patients with alcohol use disorders. Physicians score the AUDIT and start a two visit intervention for patients without alcohol dependence. In the first visit, physicians address unhealthy drinking, explore patients' interests in changing their behavior, and encourage patients to keep a log of alcohol consumed. At the second visit, physicians review the log with the patient and assist with setting goals to reduce unhealthy drinking. Patients with alcohol use disorders are referred for more intensive treatment.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Number of patients screened, proportion of eligible patients who are appropriately offered counseling or referred, and how faculty perceives the usefulness of the guides.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): In the first 3 months of the program, we screened 1,695 patients. Of those patients, 5 % ($n=87$) screened positive and completed the AUDIT. We performed chart reviews of 74 patients who screened positive. In the clinic note, physicians mentioned alcohol use in 54 % ($n=40$) and documented counseling in 38 % ($n=28$). Three of the 74 patients screened positive for alcohol use disorders, but none of these patients were referred to alcohol use treatment programs. A provider survey was distributed after implementation of the prompt. Of the 11 providers who responded, 80 % ($n=9$) felt that the guides were helpful.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): We have been successful at implementing alcohol screening in our practice to identify patient with unhealthy alcohol use. We developed resources to guide physicians

through screening and motivational counseling. Our next step is to improve the consistency with which we counsel, refer patients with alcohol use disorders, and document our interventions.

IMPROVING ATTENDANCE TO PRIMARY CARE APPOINTMENTS: RANDOMIZED CONTROL TRIAL OF TEXT MESSAGING TO PATIENTS AT A COMMUNITY HEALTH CENTER Sanja Percac-Lima^{1,2}; Patrick R. Cronin³; Anjali Thakkar⁴; Adrian Zai^{2,3}. ¹Massachusetts General Hospital, Chelsea, MA; ²Massachusetts General Hospital, Boston, MA; ³Massachusetts General Hospital, Boston, MA; ⁴Harvard Medical School, Boston, MA. (*Tracking ID #1939188*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Poor adherence to medical appointments not only negatively impacts the quality of care, but also reduces access to care for other patients. In 2012, the Massachusetts General Hospital Chelsea HealthCare Center (MGH Chelsea) adult medicine practice had the highest no-show rate in our hospital's primary care network. A previous pilot study revealed that forgetfulness and miscommunication were the most common patients' reasons to no-show to their appointments.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Implement text messaging to patients at a community health center and using a randomized control trial (RCT) evaluate its effect on appointment attendance

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): MGH Chelsea is a community health center serving predominantly Latino, non-English speaking and low-income patients. Adult patients seen at the practice were eligible for the study and randomly assigned into two arms: 1. Control: receive usual care—a reminder phone call 2 days prior to their appointment 2. Intervention: receive usual care and text message reminder 7-days and 1-day prior to the appointment. We designed an informatics tool to automatically: (1) provide Patient Services Coordinators with electronic rosters of patients who are due for a call reminder, and (2) send text message reminders to patients prior to their appointments.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The primary outcome was the no-show rate in the control and intervention groups. The secondary outcomes included: the no-show rate by age, race, gender, language and insurance, by text message outcomes in the study arms, cancelled/rescheduled appointments and return-on-investment.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE Δ FINDINGS WILL BE DISCUSSED \square): The RCT started on August 1st, 2013 after 2 weeks of testing phase and randomization. In the intervention there were 3550 unique patients and, 716 (20.2 %) of patients consented to receive text messages, 93 (2.6 %) opted out and 2,061 (58.1 %) did not respond, and 680 (19.2 %) did not have a cell phone number. The no-show rate was slightly lower in the intervention than control (1101/6093=18.1 % vs 339/1395=19.6 %, $p=0.24$). However, in the intervention, the subgroup of appointments where patients consented to receive text messages had significantly lower no-show rate 13.3 % vs. 19.2 % ($p<0.0001$) than those who did not consent.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Improving attendance to primary care appointments in underserved populations is challenging. Although the text message intervention lowered the no-show rate, a significant number of patients do not respond to the addition of a text message reminder. Patients who consent to text messages have significantly better attendance with primary care appointments. Exploring the reasons why patients do not respond to receive messages and improving consent process to text messaging could improve the impact of the intervention.

IMPROVING COLORECTAL CANCER SCREENING UTILIZING LEAN SIX SIGMA METHODOLOGY IN AN ACADEMIC GENERAL INTERNAL MEDICINE CLINIC Shana Ratner¹; Brooke B. McGuirt¹; Kathryn A. Brennan¹; Jonathan Thornhill²; Summer Hogan²; Kim Young-Wright³; Shaun McDonald³; Thomas M. Miller¹; Michael Pignone^{1,4}. ¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²University of North Carolina-Chapel Hill, Chapel Hill, NC; ³University of North Carolina-Chapel Hill, Chapel Hill, NC; ⁴University of North Carolina- Chapel Hill, Chapel Hill, NC. (*Tracking ID #1928120*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Colorectal cancer (CRC) screening rates were sub-optimal in the University of North Carolina Internal Medicine Clinic (UNC IMC) with many potential root causes.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Use Lean Six Sigma methodology to identify root causes of the sub-optimal screening rate 2) Pilot and test methods of outreach for unscreened patients 3) Improve the CRC screening rate in the Internal Medicine Clinic

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The UNC IMC is an academic general internal medicine clinic with approximately 12,000 patients. We formed a multidisciplinary team to improve CRC screening, using Lean Six Sigma methodology. The team interviewed patients, physicians, clinic staff, and GI procedures staff to map the processes for stool cards and colonoscopy and identify barriers to screening. Root cause analysis identified 68 root causes of sub-optimal screening rates. Using multi-voting and an impact-effort grid, we chose 5 for rapid cycle improvement. We identified the exclusive use of a "visit-based approach" without supplementation from a population-based approach and poor documentation of outside studies as key root causes that we could test with chart reviews and outreach letters. We tested two approaches to overcoming these root causes: 1) sending outreach letters to patients who turn 50 and may not have scheduled visits (signed by the medical director); 2) having providers review their panels of unscreened patients to update documentation of outside studies and offer screening via personalized letters. We scheduled 17 residents and 3 attendings to complete panel reviews in phase 1 of the project.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): CRC screening rate in active clinic patients ages 50–75.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE Δ FINDINGS WILL BE DISCUSSED \square): Non-personalized letters sent to patients at age 50 had minimal success: 2 % (1/48) of those receiving letters completed screening with 3 month follow up. Physicians who performed panel reviews in phase 1 ($n=20$) had an average of 57 patients on attending lists and 16 patients on resident lists. Phase 1 physicians sent a total of 313 letters. The screening rate improved by a mean absolute increase of 5.0 % (range: -8.7 % to +18 %) in physicians who completed chart reviews and letters in phase 1 versus those who are scheduled to complete them in phase 2 (mean absolute increase 0.4 %). From January to December 2013, the overall clinic CRC Screening rate improved from 62.8 % (4609/7337) to 66.0 % (4943/7489), $p<0.0005$, with an increase in the screening rate every month since the project began.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Centralized, non-personalized outreach letters to patients at age 50 had low efficacy. Individual physician chart reviews and personalized letters coming from the PCP improved screening more effectively.

IMPROVING TRANSITION OF CARE FOR PATIENTS WITH HIGH RISK FOR READMISSION Raghib Zeitouni; Animita Saha; Katherine E. Gettys; Kelly Avey; Tamara D. Burdon. Carolinas Medical Center, Charlotte, NC. (*Tracking ID #1937631*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): A 2009 analysis of Medicare patients showed that 50 % of patients readmitted within 30 days had not seen their physician since their last discharge, poor transition not only increase healthcare cost but also has a detrimental effect on patient and their family's wellbeing.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Identifying patients with high risk for readmission at the time of hospital admission 2. Checking in with patients 2 days post discharge by a pharmacist/social worker and establishing an appointment within 5–7 days of discharge with their PCP's office 3. Validating if this process reduces readmission.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This pilot study was conducted in an Internal Medicine residency clinic where majority of patient population is uninsured or underinsured, has high disease burden and tremendously low overall and health literacy. The entire program started with formation of a team which involved Faculty physicians, Internal Medicine residents, nurses, pharmacist, social worker, case managers and quality improvement (QI) coaches. This started initially as part of an AHRQ funded ImPact grant where our clinic participated but then we continued with it even after the grant ended. Inpatient staff team used IHI risk stratification tool to determine post discharge follow up in clinic where several slots were available to accommodate these patients. When a follow up appointment was made at the time of discharge, the scheduler sent a notification to the care provider-MD, pharmacist and social worker. This triggered a phone call by the pharmacist who according to a

checklist designed by IHI (STARR) did medication reconciliation, identified social and financial barriers limiting access to medications, food or appointment and importantly reminded the patient or family about the appointment. Presence of social or financial barriers triggered a phone call by a social worker or case manager. All communications were recorded in EMR and were available to MD's. While in the Medical home they spend time with the pharmacist, care coordinator, social worker and primary care provider. This special emphasis on medication reconciliation, barriers to care, access issues and teach back all helps the MD formulate a more comprehensive plan of care.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The most important success was bringing the team together; there was representation from every component of the clinic team who took the role of champions. The other important measure of success was collaborating with our pharmacist team who played a tremendously important role if not the most important role and realization that lack of understanding about changes in medication regimen is almost 100 % ubiquitous and perhaps one of the factors that can be impacted the most. Educating and training faculty and residents and staff in the QI process and developing an QI mindset is an important achievement of this entire process. Improved access increased the comfort level and satisfaction of inpatient care team in making smooth transition for the patients. Quantitatively, we have definitely seen that we touched significant number of high risk patients and the 2 day post discharge phone call made a tremendous impact in getting these patients to their appointment. This entire process resulted in reduction of readmission.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): During the pilot 72 patients were identified by inpatient team as high risk got an appointment within 5–7 days post discharge. We could reach 66 % of patients by phone, of which 74 % made it to the appointment. Among the group of patients that could not be reached by phone, only 12.5 % showed up for the appointment. This finding is statistically significant and shows the importance of 2 days post discharge phone call. All patients who were identified by inpatient team as high risk got an appointment within 5–7 days post discharge. We could reach 66 % of patients by phone, of which 74 % of patients made it to the appointment. Among the group of patients that could not be reached by phone, only 12.5 % showed up for the appointment. Among patients who made hospital follow up appointment, 27 % of patients got readmitted within 30 days, on the other hand 45 % of patients who did not make it to the appointment 45 % got readmitted within 30 days. These findings are statistically significant as well.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The process should start with team building with members who play key role in transitioning patients from inpatient to their medical home. Key points to remember after the initial phase are: 1. Timely Access to Care 2. Post discharge visit Planning: this needs to start before patient leaves hospital 3. Two days post discharge phone call by pharmacist and SW/care managers

INNOVATION IN SHARED MEDICAL APPOINTMENTS (SMAS) FOR DIABETES MANAGEMENT: ENGAGING RESIDENTS IN INTERDISCIPLINARY LEADERSHIP AND SELF-DIRECTED CURRICULUM DEVELOPMENT Christina B. Pham; Jennifer Huang; Dylan Bothamley; Patrick T. Lee; Yamini Saravanan. Harvard Medical School/Cambridge Health Alliance, Cambridge, MA. (*Tracking ID #1936691*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The shared medical appointment (SMA) is a model of care with potential to significantly improve patient experience and outcomes for patients with chronic disease. Currently, few US internal medicine residency programs provide formal training in leading SMAs. The SMA format should be integrated into residency training because it provides internal medicine trainees an opportunity to develop: 1. leadership skills to direct an interdisciplinary team 2. experience in applying quality improvement theories 3. skills that engage and educate patients in non-traditional formats

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Understand the evidence behind the SMA model and why it works for diabetes management. 2. Explore how the SMA is an effective tool for the development of resident skills in all six Accreditation Council for Graduate Medical Education's (ACGME) core competencies: patient care, medical knowledge, practice-based learning and improvement, systems-based practice, professionalism, and interpersonal skills and communication. 3. Engage, teach, and mentor residents to lead SMAs.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We developed and implemented a new structure for internal medicine resident-led SMAs for diabetic patients at the Cambridge Hospital Primary Care Center - one of the teaching clinics at the Cambridge Health Alliance - an urban safety net, Harvard Medical School-affiliated community hospital. Training residents in leading SMAs has (1) increased resident case volume and allowed for care of diabetic patients in traditional and non-traditional formats, (2) provided opportunity for leadership of interdisciplinary care teams, and (3) allowed residents a practicum to apply quality improvement principles in daily practice. We designed an SMA process where third year residents lead the planning, execution, and de-brief of an interdisciplinary team every 6 weeks. The team consists of a medical assistant, dietitian/diabetes educator, pharmacist, medical student/junior resident, senior resident, and teaching attending. During the SMA, the senior resident examines patients, engages them in active management of their diabetes, and teaches a patient-directed educational curriculum. Most importantly, however, the resident fosters an environment of peer mentorship, which patients repeatedly cite as the overarching value that keeps attendance high. At the end of the session, the resident runs a de-brief and enters ideas for process improvements into a change log that feeds into future plan-do-study-act (PDSA) cycles. The implication for this innovation is that our process can easily be replicated at other internal medicine residencies, to not only produce a cadre of physicians with evidence-based training and experience with SMAs, but most importantly, to offer more patients an effective way to manage their diabetes.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): – Patient exit surveys - Qualitative one-on-one patient interviews - Provider exit surveys - Patient attendance and attrition data - Clinical diabetes metrics

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): – Improved patient satisfaction with self-management of their diabetes based on formal exit interviews - Marked enthusiasm and positive feedback on evaluations from patients, who are requesting more frequent sessions - Resident's active leadership of an interdisciplinary team surrounding diabetes management - Structured resident training in the mechanics of SMA implementation - Development of resident skill set in leading SMAs and designing curriculum based on patient needs and quality improvement metrics - Based on formal evaluations, marked enthusiasm and positive feedback from residents, who are requesting to lead more sessions than originally planned

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The SMA is an effective format for care of diabetic patients. There is increased patient empowerment and satisfaction with self management of their disease. The SMA is an effective tool for the development of resident skills in the ACGME core competencies. **FEASIBILITY OF MAINTAINING PROGRAM AND TRANSFER TO OTHER PROGRAMS:** We have shown that this program can be run and maintained by a staff of one to two medical assistants, one medical student or junior resident, one diabetic educator, one resident physician, and one attending preceptor. We run our 120 min groups (60 min for all labs, exams, community time; 60 min for formally led group time) on a 6-week cycle, which is proving sustainable for both providers and patients. Importantly, this structure was scalable to a financial break-even point at approximately 12 patients per SMA session. With the commitment of program leadership and the allocation of appropriate staffing for the project, this structure can be implemented by internal medicine programs with large diabetic populations.

INTEGRATING BEHAVIORAL HEALTH SERVICES AND PRIMARY CARE AT AN URBAN, SAFETY-NET TEACHING HOSPITAL: A PILOT PROGRAM Christine A. Pace¹; Joanna Buczek²; Alissa Cruz¹; Lee Ellenberg¹; Foote Jonathan²; Ellen W. Gimman¹; Cindy M. Gordon²; Hannah M. Marks¹; Robert Sokolove^{1,2}; Jeffrey H. Samet¹; Charlotte Wu¹. ¹Boston University School of Medicine, Boston, MA; ²Boston University School of Medicine, Boston, MA. (*Tracking ID #1923614*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Although behavioral health conditions are known to affect the overall health of primary care patients, barriers to effective behavioral health care at Boston Medical Center's Adult Primary Care Clinic (including the lack of systematic behavioral health screening and the delivery of most behavioral health services in another department) have led to missed opportunities for early identification of these conditions as well as gaps in patient access and coordination of care.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To improve early identification of depression and unhealthy substance use; improve access to psychotherapy and substance use counseling; and improve the quality of on-site care for depression and unhealthy substance use through primary care provider trainings and collaborative care protocols.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Boston Medical Center's Adult Primary Care Clinic is a 36,000-patient practice at an urban, safety-net, academic teaching hospital. This pilot program of integrated behavioral health services is located in one of the clinic's six teams, with the goal of spreading an optimized program across all teams. The pilot involves the following new elements: 1) Standardized, annual screening for depression and unhealthy substance use, initiated by front desk staff and medical assistants; 2) Short-course psychotherapy and substance use counseling by an on-site, full-time licensed clinical social worker (LICSW), with facilitated referrals to specialty behavioral health for patients requiring long-term treatment; 3) A community resource expert who connects patients with resources such as food stamps or transportation; 4) Depression care management, modeled after IMPACT, in which the LICSW collaborates with providers to assess, educate and counsel patients with depression and adjust treatment as needed; 5) Staff and provider training on the rationale for behavioral health screening, the screening and referral workflows, and, for providers, brief interventions for unhealthy substance use and evidence-based depression treatment in primary care.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Metrics include: 1) Proportion of patients who receive annual screening for depression and unhealthy substance use; 2) Of patients referred to the LICSW: a) proportion given an appointment within 14 days; b) proportion who attended their appointment; 3) Proportion of patients with a diagnosis of depression who have a recorded PHQ9 score in their medical record; 4) Provider satisfaction with behavioral health services, measured by pre- and post-intervention surveys.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *â€œFINDINGS WILL BE DISCUSSEDâ€*): A 26 question pre-intervention survey was completed by eight attending providers and five residents ($n=13$). PHQ9 and referral data were obtained from hospital databases. Early pilot metrics will be available in April. Baseline findings include: 1) Approximately half of providers reported annual screening for depression with the majority of patients. All providers reported annual screening for unhealthy substance use with the majority of patients, but few reported consistently doing brief interventions. Providers reported a low level of staff assistance with screening. 2) With 10 being the highest score, the average satisfaction with available behavioral health services was 4.4. Although providers rated the importance of communication with behavioral health specialists as 8.4, the average rating for communication with these specialists was 3.6. 3) In a review of referral data over two week-long periods of the 2012-13 academic year, 100 % of adult primary care patients referred to the specialty Behavioral Health clinic were given appointments for a group clinic orientation, but only 25 % percent attended a clinical intake visit within 6 months. 4) Of patients with depression in their problem list, only 2.5 % had a recorded PHQ9 score in their record prior to the pilot.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our novel pilot program of behavioral health integration in a safety net, academic hospital primary care setting has yielded several lessons: 1) Customizing screening workflows to our clinic and electronic record was challenging, requiring months of pre-testing with staff and problem-solving with the multi-disciplinary team. Such efforts, however, heightened staff engagement and helped us anticipate problems prior to implementation. 2) Despite the pilot's small scale, each step has benefited from extensive collaboration between Behavioral Health and Primary Care. To ensure that participating providers and administrators have sufficient time for the project, such collaboration has required buy-in from departmental leadership, with a plan for sustainability and dissemination. 3) Even with high levels of institutional support and interdisciplinary collaboration, it is challenging to support non-billable efforts from providers such as psychiatrists when fee-for-service payment still dominates. Creativity is required to adapt evidence-based models such as IMPACT in an era of mixed payment models.

INTEGRATING CARE FOR HEPATITIS C VIRUS INFECTION WITH OFFICE-BASED THERAPY FOR OPIOID DEPENDENCE Christine A. Pace^{1,2}; Judith I. Tsui^{1,2}; Claudia Nader³; Lexie P. Bergeron²; Colleen T. LaBelle²; Jeffrey H. Samet^{1,2}. ¹Boston University School of Medicine, Boston, MA; ²Boston

Medical Center, Boston, MA; ³St. Elizabeth's Medical Center, Brighton, MA. (*Tracking ID #1942516*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Individuals receiving opioid agonist treatment (OAT) are an accessible population with very high HCV prevalence, yet a minority of them receive appropriate HCV care, including treatment.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) To provide on-site HCV care (including counseling, education, and appropriate testing) for treated opioid dependent patients in general internal medicine clinics. 2) To increase the number of opioid dependent patients who receive pharmacotherapy for HCV.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The HCV-OBOT Program grew out of a desire to provide integrated HCV and substance use treatment in a population with a high prevalence of HCV. The Office-based Opioid Treatment (OBOT) Program based in the General Internal Medicine (GIM) clinic at Boston Medical Center has been in existence since September of 2003. It is a collaborative care model in Primary Care between nurse care managers and physician generalists to provide treatment (primarily buprenorphine/naloxone) for opioid dependent patients. It cares for over 400 patients, approximately half of whom are infected with HCV. The goal of the program is to reduce barriers to appropriate HCV care including treatment by providing on-site care for HCV. The program building on existing OBOT resources, including 3 full-time nurse care managers, was initiated by two physicians with HCV treatment experience, one an infectious disease specialist and the other a general internist/addiction specialist.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1) Number/percent of OBOT patient who receive appropriate confirmatory testing (HCV viral load). 2) Number/percent of OBOT patients who undergo HCV evaluation. 3) Number/percent of OBOT patients who are treated for HCV.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *â€œFINDINGS WILL BE DISCUSSEDâ€*): The HCV-OBOT Clinical Pathway was established in spring of 2010. In 2011, there were 424 patients enrolled in the OBOT program. Ninety-seven percent were screened for HCV on intake, and of those screened, 227/55 % were antibody positive, a slightly lower prevalence than that observed in methadone clinics. Among seropositive patients, 209/92 %, had an HCV viral load test completed, and of those, 157/75 % were positive demonstrating chronic infection. Nearly one-half of those (70/45 %) agreed to see an HCV medical provider and received an appointment, but only 42/60 % kept their appointment. Most medical visits centered on education, counseling, and work-up towards treatment. Ten patients have been treated, representing 6 % of the eligible sample, and eight patients have been cured of HCV.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): We found that it was feasible to implement a pathway for providing on-site HCV care in a large office-based opioid treatment (OBOT) program. Patients were receptive to receiving HCV care in conjunction with treatment for their opioid addiction. Although the no-show rate for appointments was high, the clinic provided an opportunity for a small number of patients to be cured of their infection. Challenges to be addressed in the future include overcoming misconceptions at the patient and provider level regarding HCV treatment, and navigating rapidly changing treatment options.

INTENSIVE PRIMARY CARE FOR HIGH READMISSION RISK ADULTS Colleen Lynch; Ania Wajnberg; Mathew Jacob; Maria Basso Lipani; Susan Bernstein; Claudia Colgan; Jill Kalman; Alex Federman. Mount Sinai School Of Medicine, New York, NY. (*Tracking ID #1933012*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Does intensive, team-based primary care consisting of low patient/provider ratios, open access, and social work services improve outcomes for high risk adults?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To examine the impact of intensive primary care on hospital stays, emergency department (ED) visits, and outpatient quality measures in a population of adults with high risk of readmission.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR

COMMUNITY CHARACTERISTICS: Mount Sinai Medical Center created the current Internal Medicine Associates- Preventable Admissions Care Team (IMA/PACT) primary care clinic in the fall of 2012. Patients are referred from PACT, an inpatient social work- led transition program begun in 2010 that has been shown to reduce hospital utilization. Core to the model is connection to a medical home; patients that do not have a primary care provider are referred to IMA/PACT. Patients are also referred by physicians within the Sinai system if they have similar high-risk criteria as the PACT program, including >2 ED visits or hospital admissions in the past 6 months, ≥3 chronic illnesses, and psychosocial complexity. Psychosocial complexity is subjectively determined based on markers including low income, low health literacy, psychiatric diagnoses, housing instability, and substance abuse. IMA/PACT is housed within the IMA clinic, an urban academic training practice. Care is delivered by teams consisting of 1 physician (MD), 1 nurse practitioner (NP), and 1 social worker (SW). Two teams are currently active and each team manages a panel of 200 patients. MD and NP roles are similar in terms of patient care, but MD team members provide NP oversight and clinical support. Providers become familiar with the entire team's patients, and patients can see either panel provider for urgent visits. Open access is achieved by reserving one third of provider's daily slots for urgent visits. Patients see their SW at every scheduled MD/NP visit, allowing for rapid evaluation of psychosocial issues and ongoing supportive care for mental health and chronic illness management. New visits are 1 h, and follow up or urgent visits are 30 min in duration for all (MD/NP/SW) visits. Team meetings are held weekly and the clinic is physically within one hallway, allowing for real-time communication around active patient issues. The high level of collaboration between MD/NPs and SW results in a holistic approach to patient care.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We are comparing 6- and 12-month all-cause ED visits and hospitalizations before and after IMA/PACT enrollment with a concurrent control group of patients not enrolled in the program but matched by clinical risk and healthcare utilization characteristics. We will also assess the program's impact on intermediate outcomes like blood pressure control and HgbA1c values, and on process measures like receipt of vaccinations and diabetic retinopathy screening.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *“FINDINGS WILL BE DISCUSSED”*): From September 2012 to October 2013, 171 new patients were enrolled in the program, 77 % from the PACT program. The average age is 63 years, 63 % are female, 70 % have Medicare, 45 % have Medicaid, and 18 % are dually eligible. The average number of chronic medical conditions is 7; diabetes, hypertension, and asthma/COPD are the most common. Preliminary data show a 27 % reduction in hospital stays and a 44 % reduction in ED visits in the 6 months after program enrollment.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Patients at the highest risk for ED visits and hospital stays may benefit from intensive, multidisciplinary team-based primary care.

INTERPROFESSIONAL TRAINEE DEVELOPMENT OF AN AFTER VISIT SUMMARY IN A COMMUNITY-BASED OUTPATIENT CLINIC TO IMPROVE PATIENT SATISFACTION Chelsea Bowman¹; Eugene Fan¹; Joseph A. Hippenstein¹; Anna Strewler²; Jonathan Van Nuyts^{2,1}; Daniel Wheeler¹; Shalini Patel^{2,1}; Meg Pearson^{2,1}. ¹University of California, San Francisco, San Francisco, CA; ²Veterans Affairs Medical Center, San Francisco, CA. (*Tracking ID #1928178*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): An after-visit summary (AVS) improves patient satisfaction in regards to patient-provider relationships and communication. However, our community-based outpatient clinic (CBOC) had no standardized mechanism to provide patients with an AVS.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Develop an AVS incorporating contributions from patients, staff and providers 2) Increase percentage of patients who receive an AVS 3) Increase overall patient satisfaction with understanding of their treatment plan

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): An interprofessional team consisting of internal medicine residents and nurse practitioner (NP) trainees led by clinic attendings formed to improve written communication at our CBOC. First, we surveyed patients, staff and providers to assess the perceived need for an AVS and to identify key content areas to include in the summary. The survey data was used to create a prototype AVS, which was distributed to all clinic staff for feedback and revision. We piloted this revised AVS with select providers to determine ease of use

prior to dissemination. The AVS was distributed to all providers who maintained a primary care panel in the clinic including 5 internal medicine attendings, 12 internal medicine residents and 1 NP student. We collected patient survey data to establish current baseline practices of providing written communication and patient satisfaction scores on communication. These surveys were continued after AVS distribution to evaluate the effect of the intervention.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The primary outcome was defined as the percentage of patients who received written communication after their clinic visit; our goal is to increase this percentage from 73 to 90 %. Our second goal is to increase the percentage of patients that "strongly agree" they understand their treatment plan and increase patient overall satisfaction with the understanding of their treatment plan. Outcomes will be based on the patient survey data collected both pre- and post-AVS implementation.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *“FINDINGS WILL BE DISCUSSED”*): Key content areas identified by both providers and patients considered beneficial for an AVS included: medication changes, when to get laboratory or radiology tests, pending referrals and next appointments. While 81 % of providers reported they used written communication at clinic visits, only 73 % of patients reported they received written communication prior to AVS implementation. An overwhelming percentage of providers preferred a written AVS compared to a computer based AVS, 82 % vs. 18 % respectively. A preliminary pilot of the AVS showed an increase in patient reported receipt of written communication from 73 to 83 %. In addition, the percentage of patients who "strongly agreed" they understood their treatment plan increased from 56 to 67 %. Similarly, patients overall satisfaction with their understanding of the treatment plan increased from 81 % (62 % strongly agree and 19 % agree) to 89 % (33 % strongly agree and 56 % agree). AVS dissemination and data collection are ongoing.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Incorporating patient, staff and provider preferences in the development of an AVS in a CBOC can improve written communication between providers and patients and improve patient satisfaction with their understanding of the treatment plan. Incorporating clinic staff in the development of an AVS contributed to the adoption and sustainability of our project. The AVS has become a patient education tool used widely by clinic staff, including mental health providers and nurses, to help enhance communication. An AVS must be appropriately targeted and efficient to ensure provider participation.

INTRODUCTION OF A COPD TEMPLATE IN AN INTERNAL MEDICINE RESIDENT CLINIC TO IMPROVE DISEASE MEASURE RECORDING Jonathan N. Byrd. Washington University in Saint Louis School of Medicine, Saint Louis, MO. (*Tracking ID #1927252*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): COPD is an extremely common condition with high and continually increasing morbidity; however, failure to establish an accurate diagnosis or to document functional status, risk factors, or immunization status can lead to inappropriate management plans as well as inefficient use of physician clinic time.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Improve accurate diagnosis of COPD and condition severity 2. Improve reporting and verification of influenza and pneumonia immunization 3. Improve reporting of smoking status 4. Lead to improved allocation of clinic time and guide management decisions

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The ABIM's Chronic Obstructive Pulmonary Disease Practice Improvement Modules™ and the 2013 Global Initiative for Chronic Obstructive Lung Disease guidelines were used to identify several measures to incorporate into an EMR template to be used in the internal medicine outpatient resident clinic at Washington University in St. Louis. These measures included FEV1/FVC percent, FEV 1 %, GOLD stage, mMRC functional status grade, oxygen necessity, arterial blood gas metrics PCO2 and PaO2, history of intubation, smoking status, and pneumonia and influenza vaccination status. Interns in the residency program were used as study subjects. Planned intervention included a 15 min presentation to all interns reviewing COPD pathophysiology, diagnostic criteria per the GOLD guidelines, management approaches based on functional status and lung spirometry, and instruction on use of the COPD template in the EMR. Posters advertising the COPD template with instructions were posted throughout the resident clinic. The interns' patient panels were assessed 3 weeks prior to intervention for

number of COPD patients, documentation of COPD diagnosis, PFTs, smoking status, and influenza and pneumonia vaccination status. The interns were assessed for 6 weeks after the intervention for the use of the COPD template and documentation of above variables.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Rate of the COPD template use in the resident clinic as well as the rate of recording pulmonary function, smoking status, influenza and pneumonia vaccination status with and without use of the COPD template.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE “*Findings Will Be Discussed*”): 33 COPD patients were evaluated before intervention vs. 48 COPD patients to date (4 weeks post intervention). Template usage rate was 12.5 % (6/48). Reporting rate before intervention was 90.9 % (30/33) for smoking status, 66.7 % (22/33) for influenza vaccination, 72.7 % (24/33) for pneumonia vaccination, and 60.6 % (20/33) for PFTs. Rate after intervention among non-template users was 85.4 % (41/48) for smoking status, 68.5 % (33/48) for influenza vaccination, 68.5 (33/48) for pneumonia vaccination, and 52.1 % (25/48) for PFTs. Among template users reporting rate for these variables were universally 100 % (6/6). Notably 12.3 % (10/81) of assessed patients were not documented as having COPD despite adequate diagnostic information.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Based on preliminary data, structured tools in clinical documentation of COPD do improve incidence of recording among internal medicine residents when used; however, incorporation rate of COPD template in clinic notes was far less than expected. Additional strategies such as weekly email reminders or clinic attending instruction to encourage template use may aid in further achievement of above objectives. This tool can be used to focus clinic time on deficits including readiness for smoking cessation or need for immunizations.

LESSONS LEARNED IN IDENTIFYING PATIENT SELF MANAGEMENT GOALS AND PLANS AND ADDING GROCERY STORE BASED NUTRITIONAL SERVICES TO THE MEDICAL NEIGHBORHOOD OF A GENERAL INTERNAL MEDICINE PRACTICE Scott Joy^{1,3}; Jennifer Cullingford²; Jeannie Schwendtner²; Oswaldo Hernandez⁴; Gerardo Caldera Rosales⁴. ¹The Colorado Health Foundation, Denver, CO; ²King Soopers, Denver, CO; ³University of Colorado, Denver, CO; ⁴High Street Primary Care Center, Denver, CO. (*Tracking ID #1935130*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Criteria for certification as a PCMH specify that patients must be asked about their self management goals and plans, which often include eating a healthier diet, but follow-up for nutritional services can be variable and may not be covered by insurance plans.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Develop a self management goal/plan sheet to give to patients to understand the patient's most important goal to improve their health. Identify patients in a general internal medicine practice who choose a goal of eating a healthy diet. Identify a retail grocery store chain that offers nutritional services in metro Denver, CO, and explore opportunities for partnership between the general internal medicine practice and nutritional services led by registered dieticians that are offered at the grocery store.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A must-pass element of PCMH is that the practice develops and documents self-management plans and goals in collaboration with patients and families, provides educational resources or refers patients/families to educational resources to assist in self-management. Our academic GIM practice developed a one page, self management plan/goal form which includes the following: Graphics that represent various health goals that a patient can choose by circling the relevant graphic. Sections asking for the patient to document a written plan on how they will reach that goal. A Likert scale of 0 to 10 that the patient uses to report their confidence at changing their behavior. All patients who arrive for a clinic visit related to diabetes management are given this form by a medical assistant during the rooming process and are asked to complete the form. The provider reviews the form with the patient, the patient and provider sign the form, the document is scanned into the electronic medical record, and the patient is given the paper copy of the form to take with them post-visit. A local grocery store chain (King Soopers) offers free nutritional services to customers, including individual consultations, meal planning assistance and grocery store tours. The closest King Soopers store is 1.7 miles from the clinic practice site. These services are unique compared to nutritional services offered

within the hospital, as the majority of the education is done in the store aisles where consumers can review and discuss the nutritional value of the foods and products they frequently purchase. Nutrition education conducted in the store teaches patients to become more comfortable with label reading and choosing the nutritious while staying within their budget. Clinic leadership met with health/wellness leadership from King Soopers to develop a referral process for patients to connect with this free nutritional service. Patients who circle the goal of eating a healthy diet are verbally informed of the King Soopers option for nutrition counseling. If a patient expresses interest in attending, a secure e-mail is sent to the King Soopers dieticians. Patients are also given a folder after the visit that includes the NDEP booklet Living with Diabetes, information regarding King Soopers Nutritional Calendar of Events, seasonal healthy nutrition/meal planning, and NuVal information. The King Soopers dietitians contact the patient by phone to schedule an appointment.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): What percentages of patients with diabetes were given the self management plan/goals form during their visit? What percentages of patients were open to receiving nutritional counseling from a retail grocery store team of dietitians?

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE “*Findings Will Be Discussed*”): Self management forms were given to 33 %, 50 %, and 100 % of patients with diabetes who had an appointment in the general internal medicine practice over the initial 3 weeks of the pilot program. To date, 10 referrals (80 % female, average age 50.3y) have been sent to the King Soopers dietitian team. All patients were contacted by telephone by King Soopers dietitians (80 % in person, 20 % unavailable, voice mail message left). Of the patients contacted in person, 3 patients (37.5 %) have had a consult scheduled (1 patient arrived, 1 patient no-show, 1 patient future appointment scheduled), 3 patients (37.5 %) requested a future phone call to schedule, 2 patients (25 %) refused an appointment.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A process can be developed to create a patient self management goal/plan form that meets PCMH criteria. Workflows can be developed that allow a GIM practice to provide this goal form to patients, and patients can complete the form during their office visit. A general internal medicine practice can collaborate with a retail grocery store chain to engage patients in nutritional counseling and access free services to promote healthier behaviors and choices. Clinical outcomes regarding this initiative, such as improvement in body weight, cholesterol and BP values remain to be determined.

MULTI-DISCIPLINARY HUDDLES TO IMPROVE CARE AND REDUCE COSTS FOR HIGH COST PATIENTS IN A SHARED-SAVINGS PROGRAM Gary Fischer¹; Jennifer Hall²; Pamela Dittoe²; Joanne Riley¹. ¹University of Pittsburgh, Pittsburgh, PA; ²UPMC, Pittsburgh, PA; ³UPMC Health Plan, Pittsburgh, PA. (*Tracking ID #1935538*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Patients with the highest medical costs often have psychosocial and socioeconomic barriers in addition to their medical conditions, resulting in fragmented care, polypharmacy, multiple specialists, and avoidable emergency department visits and hospitalizations.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Identify reasons for fragmented care and frequent emergency department visits and hospitalizations among high-risk, high-cost patients and develop individual, patient-centered interventions. 2. Improve the quality of care in high-risk, high-cost patients, as measured by decreasing avoidable emergency department visits and hospitalizations and decreasing fragmentation (i.e. fewer subspecialty visits). 3. Decreased the cost of care in high-risk, high-cost patients.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): University of Pittsburgh General Internal Medicine (UPP-GIM), a large, academic general internal medicine practice, with XX faculty physicians, XX residents, and XX patients entered into a shared-savings agreement with the UPMC Health Plan (HP), including its commercial, Medicare, and Medical Assistance products. The HP provides monthly data on our highest cost patients and has embedded a practice-based case manager (PBCM) into the clinic, who has access to insurance claims of all HP patients. A quality improvement team consisting of the practice medical director, division administrator, clinic nurse manager, and PBCM implemented a system of scheduled, multi-disciplinary team meetings (huddles) for each patient, with the aim of developing an individualized comprehensive care plan for the patient if needed. Huddles included the PCP, the nurses and secretary assigned to that PCP's patients, social work, pharmacy, and the

PBCM. The meetings were scheduled to ensure PCP availability, and included the resident and preceptor for resident patients. Prior to the meeting, the PBCM obtained claims information about the patient and attempted to contact the patient to determine housing situation, home supports, ability with ADLs and IADS, barriers to care including transportation or financial barriers, use of home medical equipment, and perception that care is coordinated. Anticipated interventions resulting from the huddles included increased PCP visits, consolidation or decrease in subspecialists, referral to mobile social work and behavioral health services provided by HP, assistance with transportation, and education of patient in self-management and appropriate venues to seek care.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. Decreased unplanned care as measured by visits to emergency department, urgent care centers, and unplanned hospitalizations. 2. Decreased overall costs of care for the patients enrolled in the program (i.e. claims paid by the HP in a specified time period before and after the huddle). 3. Increase in the number of patients who state that their care is "coordinated."

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *â€œFINDINGS WILL BE DISCUSSEDâ€*): There have been huddles on 8 patients so far. In 6 cases, needs were identified, including medication reconciliation, in-home assistance (including nursing, PT, OT, and speech), coordination of appointments, behavioral health and substance abuse treatment, financial assistance, dental care, transportation assistance, and housing issues. Interventions included monthly visits by mobile team for medication assistance and appointment coordination, medication review with patient by pharmacist, provision of dental discount cards, mobile social work and behavioral health teams, and increased PCP involvement during hospitalizations. Although follow-up so far as been only a few months, a decrease in unplanned utilization has been observed. By April, there will be quantitative data available on a greater number of patients.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. Close collaboration between payors and providers can facilitate improved care of high-risk, high-cost patients. 2. Multidisciplinary huddles, involving the patient's PCP and preceded by careful case review and discussion with patients, can identify potential solutions to patient needs and barriers to care, and may improve care, decrease unnecessary utilization, and decrease costs.

ON-SITE COACHING TO BUILD AN ENGAGED, SKILLED WORKFORCE FOR COLLABORATIVE CARE IN AN INNER CITY PUBLIC HOSPITAL SYSTEM

Damara N. Gutnick^{1,2}, Maura Porricolo^{4,3}. ¹NYU School of Medicine, New York, NY; ²New York City Health and Hospitals Corporation, New York, NY; ³North Central Bronx Hospital, Bronx, NY; ⁴Jacobi Medical Center, Bronx, NY. (*Tracking ID #1935127*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): While workshops expose learners to theory and skills, implementation of skills such as Motivational Interviewing (MI), Brief Action Planning (BAP) and other self-management support (SMS) strategies requires individual and team-based coaching. **OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES):** 1. To develop provider competencies in communications skills including MI, patient-centered goal setting using BAP, adherence counseling and other SMS strategies. 2. To improve provider self-efficacy and efficiency in delivering these skills in clinical practice through coaching and feedback.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The NYC Health and Hospitals Corporation (HHC) is a large public healthcare system with 11 hospitals and 6 Diagnostic & Treatment Centers. It serves a diverse inner city population of approximately 1.3 million annually. With NYS Medical Home Demonstration funding, HHC is implementing the TEAMcare model of collaborative care (Katon W et al. N Eng J Med 2010.) Care Managers (CMs), with supervision of a psychiatrist and internist team, work closely with patients with comorbid chronic illnesses including depression. The goal is to coordinate care, provide SMS, and facilitate patient-centered goal setting and patient engagement. Rapid delivery system redesign demands practice-based support. We describe an innovative coaching program designed to develop care teams that consistently utilize Motivational Interviewing (MI), Brief Action Planning (BAP) and other self-management support (SMS) strategies with their patients to improve health outcomes and staff satisfaction. Two HHC network coaches provide biweekly hands-on and telephonic support to care teams at 15 HHC ambulatory practices. Coaches use direct observation, and role-play,

with individuals and groups, to identify gaps and inefficiencies in the care of patients with complex situations. Short (5–7 min) live coaching mini-sessions during routine clinical care, target topics such as adherence counseling and effective ways to give information and advice. Nurses quickly learn to recognize the emergence of commitment language ("change talk") as a cue to begin patient-centered action planning, start using reflections, affirmations and summaries to evoke change talk, and effectively integrate SMS into clinical practice to increase patients' self-efficacy and engagement. The following two coaching examples provide further understanding. A CM identified time management as a personal challenge. Overwhelmed by the number and breath of patient complaints, she questioned her ability to complete a visit within the allotted time. Using role-play, the coach identified inefficiencies in the way she elicited patient concerns and then introduced skills for upfront agenda setting through "surveying," and a method for giving information and advice using "ask-tell-ask" to structure the visit. Role-play allowed the learner to practice these skills and build confidence prior to real-practice application. Another CM described frustration related to a depressed patient who was unfocused and "cried during the entire visit." Coaching included effective use of silence, "naming the emotion," reflective listening, and affirmations. The CM practiced via role play, while the coach provided instant feedback. This process resulted in the CM preparing specific affirmations of her patient's inner strengths to use during the next visit. Even brief targeted coaching interventions of 5–7 min delivered by the coach during a busy HTN treat-to-target clinical session, were perceived as helpful by nurses who had previously attended an introduction to MI session but admitted they had not applied any of the skills into practice.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. Increasing self-efficacy of CM's in applying new skills into clinical practice. 2. Shortening the time and ease of TEAMcare implementation via skill-building.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *â€œFINDINGS WILL BE DISCUSSEDâ€*): Generating staff "buy-in" for any initiative is challenging in today's healthcare environment. Despite attending an introductory MI workshop, nurses were unable to apply the skills to clinical practice. Coaching expedited skill building and increased CM self-efficacy and engagement, which created enthusiasm for successful program implementation. CMs perceived the use of MI, BAP and SMS strategies as not only effective, but also efficient. For example, one nurse reported that she was surprised at her patients' baseline knowledge of HTN self-management and that the "Ask-Tell-Ask" technique "saved time," by permitting her to target patient specific knowledge gaps as opposed to providing a standard health education message to all.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): On-site coaching is a pragmatic way to develop communication competencies of healthcare providers and accelerates implementation of innovative practice models by increasing self-efficacy of adult learners (CMs). It also facilitates PCMH transformation by building a more empowered and engaged workforce.

PRIMARY CARE PROVIDER FEEDBACK FOR IMPROVING CLINICAL PROGRESS REPORTS ON WEIGHT MAINTENANCE

Michael Eng; Kathleen M. McTigue; Laurey R. Simkin-Silverman; Kimberly A. Huber; Lacey Funair; Molly B. Conroy. University of Pittsburgh, Pittsburgh, PA. (*Tracking ID #1925673*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Clinical progress reports for referring primary care providers (PCP) are an essential component of delivering a behavioral lifestyle program in coordination with primary care; the content, format, and delivery method of reports that best suits PCPs is unknown.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): -Design a simple but informative clinical progress report to provide referring PCPs real-time updates about their patients' participation in a weight maintenance behavioral lifestyle program -Obtain feedback from PCPs about how report could be improved to better suit their needs -Describe feedback from PCPs used to improve clinical reports

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The clinical progress reports were developed as part of the Maintaining Activity and Nutrition through Technology-Assisted Innovation in Primary Care (MAINTAIN-PC) study. The goal of MAINTAIN-PC is to evaluate the use of Health Information Technology (HIT)-delivered tools and health professional support to help primary care patients

successfully maintain weight loss. Specifically, we have developed a flowsheet for weight, diet and physical activity data and standardized patient surveys; both tools are used to deliver a coaching protocol through the patient portal of the electronic health record (EHR). We are recruiting primary care patients and their providers from a group of outpatient clinics affiliated with University of Pittsburgh Medical Center (UPMC); a PCP referral is required for study participation. PCPs of patients randomized to the coaching arm of the study will receive clinical reports delivered via the EHR 24–48 h prior to routine clinic appointments. PCPs of patients randomized to the tracking (control) arm of the study will receive paper clinical reports delivered on an annual basis, and not necessarily in coordination with patient care.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Prior to start of recruitment and randomization, we asked PCPs for feedback on a draft of the clinical progress report we had designed for MAINTAIN-PC. The report was a one-page, brief summary of patient progress to date, interpretation of patient data (e.g., current patient strengths and challenges), and recommendations, including tips for PCP counseling. At the bottom of the report was a graph of patient weight since starting MAINTAIN-PC. Data for the progress report will be obtained from the patient-entered flowsheets and from subjective comments provided by coaching staff. We asked PCPs to comment on the content, format and delivery method of the report draft. We used both a written survey as well as structured interviews to gather PCP feedback; we gathered feedback until we reached thematic saturation. We plan to ask the referring PCPs for additional feedback on the reports and other aspects of the MAINTAIN-PC at 1 year and 3 years after beginning the program.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE “FINDINGS WILL BE DISCUSSED”): We received feedback on the draft report from 17 PCPs. Responding PCPs included those in large, academic practices as well as those in smaller, private practices. The content that they rated the highest was the weight graph and the tips for PCP counseling. The brief format was favorably rated, but they requested more bulleted information and fewer paragraphs of text. There was a wide range of responses for preferred method of delivery within EHR: patient encounter ($n=4$), referral letter ($n=4$), staff message ($n=3$), and phone message ($n=3$), and other ($n=1$) were all selected as preferred means of delivery. While formatting constraints will not allow a weight graph to be embedded directly in the report delivered via the EHR, PCPs will be able to link to graphical data.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): PCPs replied favorably about clear visualization of patient data (e.g., graphs, bulleted text) on the draft report. There was no consensus about how the report should be delivered in the EHR. With the PCP feedback, a revised progress report was created and will be implemented in the coming months.

PRIMARY CARE-BASED COMPLEX CARE MANAGEMENT FOR LOW-INCOME PATIENTS WITH MULTIMORBIDITY Julia Finch¹; Fern Ebeling¹; Lindsay Evans¹; Lisa Tang¹; Alice Y. Mao²; Rachel Willard-Grace^{2,1}; Louise Aronson^{2,1}; Leslie Dubbin^{2,1}; Anneliese Johnson^{2,1}; Reena Gupta^{2,1}; Claire Horton^{2,1}; Elizabeth Davis^{2,1}. ¹San Francisco General Hospital, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA. (Tracking ID #1940154)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): A small number of complex patients account for a disproportionately large number of our clinic's total hospital admissions.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Reduce hospitalizations and ED visits. 2) Improve patient satisfaction and functional status, and 3) Improve provider satisfaction

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The Care Management Program is embedded in San Francisco General Hospital's General Medicine Clinic, an outpatient primary care clinic. We enroll high-risk, high-utilizing patients who receive their primary care at the General Medicine Clinic. Our nurse-led interdisciplinary team conducts an initial assessment in the patient's home in order to identify the patient's individual concerns, barriers and goals for his/her health. After creating a patient-centered care plan, a health coach works with patients, primarily through a direct phone line, to achieve goals and provide health education. The nurse works closely with the patient's primary care provider to manage complex medical issues and address any urgent medical concerns. Additionally, when a patient is admitted, the Care Management Team communicates with the inpatient team and primary care provider to coordinate patient discharge, thereafter providing focused support for the following 2 weeks to help prevent re-admission. The team aims to improve patient

self-management through a focus on medication adherence, teaching about “red flags” to allow for early intervention, and appropriate use of services. As patients stabilize and improve, they are moved to less intensive levels of care and eventually graduated from the program.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We use a Microsoft Access database to track our care management activity and our patients' utilization data, including the number of admissions, length of inpatient stays, and number of Emergency Department (ED) visits. We also assess patient and provider satisfaction using surveys and input from a patient advisory board.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE “FINDINGS WILL BE DISCUSSED”): We collected utilization data from 65 patients for the year prior to enrollment in the program and the time since enrollment. After annualizing the data, we found a 41.6 % decrease in number of hospital admissions and a 9.2 % decrease in ED visits. Looking at the 45 patients enrolled in our program for at least 1 year, we see a 40.2 % decrease in hospital admissions and a 15.3 % decrease in ED visits. Qualitative interviews with 13 patients currently enrolled in the Care Management Program revealed that most patients feel much more motivated to participate in healthier behaviors and feel that their self-management skills have improved as a result of enrollment in the program. Provider surveys showed satisfaction across multiple domains: communication with patients and family members, coordination of care, monitoring chronic conditions, referrals to community resources, and efficiency of office visits.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Nurse-led interdisciplinary teams that provide focused care and support for high risk patients can decrease the number of expensive hospital admissions and ED visits. Trusting relationships with care team members can motivate patients to change behaviors and improve self-management. Embedding the program in a primary care clinic enhances rather than detracts from the patient's relationship with their primary care provider and helps avoid duplication of services. This type of program has the potential to improve patient care and satisfaction while also reducing costs for hospitals and insurance providers.

PROJECT RED: QUALITY IMPROVEMENT (QI) WITH EXPLORATORY AND PRESCRIPTIVE BENEFITS George Shelton¹; Aanand D. Naik^{1,2}; Barbara Trautner^{1,2}; Michael E. DeBakey VA Medical Center, Houston, TX; ²Baylor College of Medicine, Houston, TX. (Tracking ID #1934126)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Our facility's all-cause readmissions do not meet the quality benchmark set by our VA Integrated Services Network (VISN 16).

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Determine if Project Re-Engineered Discharge (RED) reduces readmissions to our hospital compared to the prior 18 months Improve inpatient discharge process flow and coordination

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our hospital readmission rates have averaged 14–15 % over the past quarter, while the benchmark for excellence is below 13.1 %. Project Re-Engineered Discharge (RED) is an 11-Element intervention, supported by the Agency for Health Research and Quality (AHRQ), which has been an effective means of decreasing readmissions in some settings. In a non-VA teaching hospital, RED demonstrated 30 % reductions in 30-day readmissions and/or emergency room visits. Our proposal adapts Project RED into the VA health care system. Each element addresses specific components of discharge planning and incorporates systems improvements within existing inpatient workflows and routines. (see below for RED element descriptions and measures).

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We will conduct a pre-post comparison of our readmission and emergency department use rates comparing FY2015 to FY2014. We will then compare our readmission rates to other VA medical centers (VAMCs) nationally and within our VISN-seeking a 25 % greater rate of improvement vs. similar sites (i.e., differences in differences, quasi-experimental design). Additionally, each element will demonstrate clinical improvements via process measure milestones specific to their element's work (below). Process Measures by Element (as measured by manual chart review and/or computer audit): 1) Patient Education - Number of standardized patient education encounters delivered during hospitalization 2) Follow-Up Appointments

-Percentage of patients with scheduled follow-up appointments prior to discharge 3) Follow-Up Tests & Studies - Number of labs/tests completed prior to hospital follow-up 4) Organizing Post-Discharge Care -Number of documented interdisciplinary team meetings within 48 h of admission 5) Medication Reconciliation - Percentage of patients with appropriate beta-blocker documentation 6) Guidelines Fidelity-Number of Case Manager Checkpoints completed within 48 h of patient admission 7) Action Plan for Problems -Number of patients receiving instructions on who to call should problems arise 8) Discharge Summary - Number of discharge summaries sent to PCP with complete discharge instructions 9) TeachBack Confirmation -Documented use of TeachBack at discharge 10) After Hospital Care Plan - Number of patients receiving a patient-centered After Hospital Care Plan 11) Post-Discharge Phone Call -Number of Patient-Aligned Care Team (PACT) phone calls completed within 48 h of discharge

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE $\alpha\alpha$ FINDINGS WILL BE DISCUSSED \square): In Project RED's pilot phase, all-cause readmission rates decreased to 11.1 % and 12.4 % in successive months, the lowest in 18 months. It is unclear if these changes are due to early Project RED efforts or are sustainable; however, we will evaluate this going forward. Project RED process measures (above) show gradual improvements. In our pilot phase, the scheduling of follow up appointments before discharge increased by 11 % to 57 %. Further, appropriate beta-blocker documentation has increased by 8 % to 83.8 % and patient discharge instruction documentation increased by 9 % to 84 %.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Project RED has dual benefits of methodically uncovering system design issues in the discharge process while providing a framework to resolve them. Emphasis on evidence-based solutions has been a tool to strategically loosen staff fixations on the familiar but unsuccessful methods of delivering care. Project RED at our VAMC also capitalizes on mandatory hospital-wide lean management training which refocuses staff efforts away from individual performance and towards the systems and structures individuals perform within. Project RED facilitated breaking down clinical silos and streamlining discordant work. The silos impeded effective system redesign as some hospital staff were unaware of complimentary, duplicating, or sometimes contradictory efforts. By strategically ensuring that each element team had voices from QI, medical care, and operative care, we funneled projects from the larger hospital into Project RED. Project RED leaders also attend monthly systems redesign meetings that cut across clinical divisions and help establish a shared understanding between Project RED and other VA QI work. Lastly, coordination between and within element teams was challenging, yet vital. Aspects of one element's work overlapped with or hinged upon the work of other element teams. Individuals also had varying levels of understanding of and motivation for adopting lean management principles. Thus, we appointed facilitators who attend all element team meetings to: 1) review lean management and systems redesign principles, 2) inform of synergistic work, and 3) facilitate progress forward.

QUALITY INITIATIVE TO INCREASE PROVIDER USE OF URINE DRUG TESTING FOR CHRONIC PAIN David S. Levitt^{1,2}; Nicholas Meo^{1,2}; Christopher P. Chen^{1,2}; Christopher M. Murphy^{1,2}; Christopher Vanderwarker^{2,1}; Joyce E. Wipf^{2,1}; Catherine P. Kaminetzky^{2,1}. ¹University of Washington, Seattle, WA; ²VA Puget Sound Health Care System, Seattle, WA. (Tracking ID #1935800)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Prescription opiate misuse and abuse has become a patient safety crisis in the United States with unintentional overdoses and deaths rising dramatically in recent years.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Our overall goal was to promote safe and responsible use of opiates in chronic non malignant pain amongst providers in our local primary care clinic, where 8 % of patients on are a narcotic pain contract (NPC). Urine drug testing (UDT) is recognized as essential practice to safe opiate prescribing. In November 2012 only 27.9 % of patients in our clinic on a NPC had UDT in the last year. Our primary objective was to increase the rate of UDT completed annually by providers, so that no provider had a rate less than 60 %.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This quality improvement project was completed in 3 phases. In the planning phase, a retrospective chart review was performed examining all patients on NPCs as of November 1, 2012. Data collected included the date of last clinic visit, provider, opiate medication, dose, quantity, and last fill date. Inclusion criteria included primary care patient on a narcotic pain contract. Exclusion criteria included cancer diagnosis or current fentanyl prescription. The intervention phase began by holding an educational session with providers. State and national safety data with current clinic baseline measures were presented. As a

group, a goal UDT target rate was identified. Panel information was provided to providers, including patient name; last UDT; and narcotic drug name, dose, and quantity of last fill. Providers were shown benchmarked summary statistics and encouraged to audit a small selection of charts from their panel. Finally, the electronic medical record template for the NPC note was modified to include a lab order hyperlink to facilitate ordering of the UDT. The post intervention phase assessed the number of patients on NPC, morphine equivalent dosing and the provider UDT rate. A regularly populated report was generated for sustainable improvement and panel management purposes.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Percent of urinary drug screens completed in patients on Narcotic Pain Contract in the last year.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE $\alpha\alpha$ FINDINGS WILL BE DISCUSSED \square): The incidence of patients on a NPC with UDT rose from 27.9 to 59.4 %. Providers meeting the goal of a 60 % screening rate rose from 19 to 64 %. An unexpected finding was that 50 % of providers had a decrease in the number of patients in their panel on a NPC in the post intervention assessment. The number of patients on a NPC serves as a surrogate measure of patients on chronic opiates because our pharmacy will not process chronic opiate prescriptions without a NPC.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): UDT in patients receiving chronic opioid therapy is central to safe opiate prescribing and was identified as an area for improvement in our clinic. We dramatically increased the percentage of patients with UDT by providing benchmarked data to providers and embedding UDT ordering into the narcotic pain contract workflow. Our intervention also had the unexpected effect of decreasing the absolute number of patients receiving opiates in clinic.

REAL-TIME PATIENT SURVEY DATA DURING REAL-TIME CLINICS: IMPLEMENTING TECHNOLOGY-ENHANCED RAPID-CYCLE QUALITY IMPROVEMENT James L. Wofford; Claudio L. Campos; Sheila R. Stevens; Robert E. Jones. Wake Forest University, Winston-Salem, NC. (Tracking ID #1934790)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Surveying patients is increasingly important for evaluating and improving healthcare delivery, but practical survey strategies during routine care activities have been challenging.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To assess the feasibility of using an integrated data management tool for conducting patient surveys during routine office care activities at a community health center primary care clinic

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We studied the feasibility of implementing a commercially available integrated data management tool (web-based survey creation, deployment on tablet computers, cloud-based management of survey data, and real-time web-based accumulation and display of survey results) in conducting patient surveys. Over a 1 month period, we conducted four patient surveys, each consisting of three questions focused on a specific patient care domain (dental care, waiting room experience, care access/continuity, and internet connectivity). Surveys were conducted among patients attending a clinic appointment on 1–2 designated survey days each week. Clinic personnel (nurses and secretaries) offered and proctored the tablet computer survey.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Number of patients provided the survey. Percent of patients completing survey. Time to complete the survey and individual questions.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE $\alpha\alpha$ FINDINGS WILL BE DISCUSSED \square): Of the 727 patients who attended office visits during the clinic days when a survey was being offered, 316 patients (43.4 %) attempted the survey, and 293 (40.3 %) ultimately successfully completed the survey. For the four 3-question surveys, the average time per survey was overall 40.4 s, with a range of 5.4 to 20.3 s for individual questions. Yes/No questions took less time than multiple choice questions (average 9.6 s versus 14.0). Average response time showed no clear pattern by order of questions or by proctor strategy, but monotonically increased with number of words in the question (<20 words, 21–30 words, >30 words) - 8.0, 11.8, 16.8, seconds, respectively.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): This

technology-enabled data management system was successful in capturing patient opinions, accelerated turnaround of survey data, and had minimal impact on a busy primary care clinic. This new model of data collection and management is feasible and sustainable in a busy office setting, supports and engages clinicians in the quality improvement process, and harmonizes with the vision of a learning healthcare system.

REDESIGNING A RESIDENT CONTINUITY CLINIC TO PROVIDE EFFECTIVE POPULATION HEALTH MANAGEMENT Alex H. Cho¹; Mark Dakkak¹; Adia K. Ross¹; Wei Duan-Porter^{1,3}; Lynn Bowlby¹; Daniella A. Zipkin¹; Lawrence Greenblatt¹; Natasha T. Cunningham^{1,2}; Jessica Simo⁴; Gina Green⁴; Holly Causey⁴; Benjamin Smith⁴; Chris Samples⁴; David Zaas¹; Aimee K. Zaas¹; Eugene Z. Oddone^{1,3}. ¹Duke University School of Medicine, Durham, NC; ²Duke University School of Medicine, Durham, NC; ³Durham VA Medical Center, Durham, NC; ⁴Duke University Health System, Durham, NC. (*Tracking ID #1936906*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): How does an adult medicine safety net clinic predominantly staffed by residents reinvent itself to provide more effective population health management?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Reduce excessive care utilization by patients with co-morbid mental health and substance abuse disorders. 2. Improve post-hospitalization follow-up for clinic patients. 3. Improve continuity and quality of patient care and resident education, simultaneously.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Over a 2 year period, the Duke Outpatient Clinic (DOC), a resident clinic caring for underserved and uninsured patients, undertook an effort to restructure its services to better serve its population and address avoidable utilization of ED and inpatient care. An overarching Six Sigma DMAIC framework (define; measure; analyze; implement; control) was used. Improvement of resident education was also an important goal. Three major interventions were proposed, and financial modeling done to make a case for the initial investment required; these were launched in July 2013: Clinic-based mental health-primary care coordinated care model To address the needs of DOC patients with co-morbid mental health conditions and high rates of ED and inpatient utilization, the HomeBASE program was created. This complex medical management intervention is supported by a care team consisting of two care managers, social worker, a mental health-trained advanced practice provider (MH-APP), and a dually trained medicine-psychiatry attending (MPA). Patients in the program are stratified into four levels of care management that vary by intensity. Detailed care plans created and entered into their records to guide other providers. All patients in the program also receive enhanced same-day clinic access to the MH-APP. The MPA supervises resident providers and provides onsite consultation. Managing post-discharge transitions of care Discharge from the hospital is a vulnerable time for patients in bridging care and maintaining accurate medical records and medication lists. To improve their transition to primary care, a team consisting of DOC front desk staff and pharmacists was formed to contact patients and perform medication reconciliation in advance of a structured post-discharge clinic visit. Clinic-based resident ‘firms’ Continuity had been a major challenge, not just between resident providers and their patients, but also between residents and their attendings. Acting on a resident proposal, a clinic-based ‘firm’ structure was adopted, in which residents are organized into teams with a lead attending, secondary attendings, a lead RN, and two certified medical assistants. These ‘firms’ are also now the basis for population management and quality improvement efforts.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): A ‘dashboard’ of metrics, updated quarterly, was created to monitor key components of the DOC redesign; including resident-attending and resident-patient continuity, post-discharge phone contacts and follow-up appointments, and the relatively hard outcomes of utilization (i.e., ED visits and hospitalizations) and direct costs for these services.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE ‘FINDINGS WILL BE DISCUSSED’): Findings 3 months after the start of implementation are promising. Ninety-four percent of resident clinic sessions were scheduled with assigned attendings and 42 % of patient visits were with resident PCPs. Every DOC patient who could be contacted was within 2 business days of hospital discharge, and the percent of patients with follow-up appointments within 14 days of discharge increased from 59 to 84 %. The coordinated care program has enrolled 38 patients; their ED visits and hospitalizations have decreased, driving a reduction in both

numbers for the clinic overall. Direct costs for the inpatient care of DOC patients are \$300,000 lower compared with the same period a year ago.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

Many academic resident-based primary care clinics care for socially and medically complex populations. Optimal patient care and resident education need not be mutually exclusive ideals. The DOC redesign for improved population health management and resident education was based on the Six Sigma DMAIC approach (Define, Measure, Analyze, Implement, Control). Interventions were designed over the course of a two-year iterative process that sought from stakeholder groups, conducted some pivotal pilots, and reviewed the internal and external landscape. Continuous monitoring of a ‘dashboard’ of metrics will guide further refinements, improvements, and expansions of these interventions at the DOC going forward. The clarity of goals and focus in execution facilitated by the use of the DMAIC framework have been critical to its success. In addition, leaders of resident clinics may not be accustomed to making more than broad economic arguments for investment in changes they are advocating; we found that making a specific financial case was critical to understanding what would be sustainable long-term, and earning the support of health system leadership.

REDUCING NON-URGENT EMERGENCY ROOM VISITS DURING PRIMARY CARE BUSINESS HOURS: A COLLABORATIVE APPROACH

Alexandra Norcott^{1,2}; Esterina Anderson^{1,2}; Sarah Dann^{1,2}; Anne Hyson^{1,2}; Cali Luco^{1,2}; Emily M. Meyer^{1,2}; Susan A. Zapata^{1,2}; Rebecca Brienza^{1,2}. ¹U.S. Department of Veterans Affairs, West Haven, CT; ²Yale School of Medicine, New Haven, CT. (*Tracking ID #1938708*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Emergency room (ER) overutilization for non-life-threatening issues has been closely associated with overcrowding, loss of continuity, and patient dissatisfaction. In an effort to address these challenges, the West Haven Veterans Affairs Medical Center (WHVA) Center of Excellence in Primary Care Education (COEPCE) initiated a quality improvement (QI) project designed to decrease ER utilization for non-life-threatening issues during primary care’s (PC) regular business hours. This work is being undertaken at the WHVA through the Primary Care-ER committee and in collaboration with five other COEPCE sites across the country. The WHVA COEPCE has a strong QI curriculum and was able to combine the work of these groups with trainee clinical experience to achieve an interprofessional perspective.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): This QI initiative primarily aimed to decrease ER utilization during office hours and also aimed to promote interprofessional team learning and application of QI methods, and develop best practices for application at other clinical sites.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This COEPCE is one of several patient aligned care teams (PACTs) at the WHVA. The WHVA COEPCE consists of three interprofessional teams, which include medical doctor (MD) and advanced practice registered nurse (APRN) faculty, registered nurses (RNs), licensed practical nurses (LPNs), MD residents, APRN fellows, undergraduate clinical students, pharmacists, and health psychologists. The COEPCE provides longitudinal care for 9 % of the Veterans seen across the VA Connecticut Healthcare System, who have access to the WHVA ER. In January 2013, COEPCE began collaborating with the PC-ER committee, which includes representatives from all PC clinics as well as the COEPCE in order to optimize PC and ER resources in conjunction with ongoing QI learning with COEPCE trainees. COEPCE held small group, ER specific, problem-based learning sessions designed to teach QI methodology, with subsequent Plan-Do-Study-Act cycle initiation (PDSA). In conjunction with the committee findings and the aid of the ER staff, the COEPCE initiated a series of interventions aimed to increase visibility and accessibility of PC resources available to Veterans. Such interventions included letter campaigns, informative posters/signage, referral to PC appointments directly from ER triage, and increasing the number of PC urgent visit (UV) appointment slots available starting in July 2013.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): At baseline, low-acuity (as defined by Emergency Severity Index scores of 4 or 5) needs constituted 12.9 % of WHVA ER visits during PC business hours. We calculated the number of non-urgent ER visits during PC business hours over total number of ER visits. These values were further organized according

to where the Veteran was assigned: the COEPCE or Firm A, which implemented similar interventions but did not increase UV appointments. We also measured provider availability as assessed by number of UVs.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): A total of 13,533 non-urgent ER visits occurred between January 1, 2012 and December 31, 2012 with 1754 (12.9 %) occurring during PC business hours. A total of 12,817 non-urgent ER visits occurred between January 1, 2013, and December 31, 2013 with 1080 (8.4 %) occurring during business hours. Overall, this was a 26 % reduction in all ER visits during business hours with a 47 % reduction in the COEPCE (368 to 194) and 44 % reduction in Firm A (779 to 438). COEPCE UV's increased 41 % from an average of 15.8 visits/week prior to July 2013 to 36.2 visits/week. The average percent reduction for non-urgent ER visits during PC business hours from July 2013 to November 2013 was 48.4 % for Firm A and 59.4 % for our COEPCE.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): In an effort to quickly optimize resource allocation many interventions/changes were implemented in a brief timeframe. This approach, although practical, confounds our interpretation of which intervention was most influential. It does appear, however, that the increase in UV appointments is particularly influential as the relative reduction in ER utilization for the COEPCE was 3 % higher when compared to Firm A. We recognize that ER utilization is, in itself, multifactorial and addressing non-urgent ER utilization will require multiple distinct interventions. Going forward we will endeavor to more methodically compare interventions across different PC teams. This was the first interdisciplinary, interdepartmental, and multi-site QI project that our COEPCE participated in. It has helped us to learn about one another's challenges and make reasonable changes that would not adversely affect other departments. Our PACTs are more apt to work collaboratively together as a result of this endeavor and will inform future QI work at the WHVA COEPCE.

SAFE MED RECONCILIATION (SATISFY PATIENTS USING A MEDICAL RESIDENT EDUCATIONAL INTERVENTION TO IMPROVE OUTCOMES)

Jessica Logan^{1,2}; Cherie Arundel^{1,3}; Rebecca Swenson⁴; Ribka Ayana^{1,2}. ¹DC VA Medical Center, Washington, DC; ²George Washington University, Washington, DC; ³Georgetown University, Washington, DC; ⁴Dartmouth College, Lebanon, NH. (Tracking ID #1937806)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Does a targeted intervention aimed at improving the medication reconciliation process with internal medicine residents reduce medication errors?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): -Improve the accuracy of discharge medication lists -Improve residents' ability to perform accurate medication reconciliation

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Medication errors are an important preventable cause of adverse events. Improvement of the medication reconciliation process has been identified as a national patient safety goal by The Joint Commission (TJC).(3) A review of our patient population revealed that many patients had more than 8 medications and roughly 37 % of discharges had medication omissions, 16 % had duplicate medications, and in 75 % of cases there was a discrepancy between the discharge medication list provided to the patient and the discharge summary. An additional review of a 114 medical records revealed that 42 % of admitted patients had problem medications such as insulin, narcotics, and anticoagulants which have been associated with an increased risk of readmission. (7,8,9) Our internal data from the DCVAMC, complimented by a literature review, highlights that inaccurate medication reconciliation can lead to ineffective hospital discharges and transitions of care. While the significance of medication reconciliation is well-described, it remains error-prone and rarely formally taught to trainees. Our target populations are Internal Medicine residents and medical students rotating at the DCVAMC (18 interns/residents monthly and 16–20 students for a total of about 440 learners per academic year) and approximately 2400 patients admitted to the medicine ward annually. The purpose of this Clinical Practice Innovation is to determine if a real-time, educational intervention with residents on medication reconciliation impacts the accuracy of discharges. The SAFE MED RECONCILIATION project was a two part learning session held during morning report with residents and medical students. In the sessions, the importance of medication safety was highlighted and how to perform proper medication reconciliation was reviewed. This was complimented by a discussion of relevant quality improvement concepts. Resident performance was

assessed at the start and end of the month using an evaluation rubric. The overall impact of the study was evaluated by pre intervention and post intervention chart reviews.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Accuracy of medication list was measured by chart review before and after the intervention. A random sample of 150 discharge summaries and discharge instructions were analyzed pre-intervention and post-intervention to assess the global impact of the intervention over time. A rubric with explicit instructions to assess accuracy was used by two hospitalists and determined by consensus. Data was analyzed by each individual item on the rubric as well as analyzed by summative score. The following variables were assessed: extraneous medications, duplicate medications, medication omissions, discrepancies with discharge summary, if medications were sorted by disease, if pharmacy medication reconciliation was done and number of medications. The number of admissions was also collected.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): Chart review revealed our population to be vulnerable to medications errors with 57 % of patients having more than eight medications on discharge and 17 % having more than 15 medications on discharge. Preliminary data of the 150 discharge instruction revealed that in the pre intervention group there were 14.67 % extraneous medications compared with 6.67 % in the intervention group. Pre intervention there were 30.67 % medical records with a discrepancy between the discharge medication instructions and the discharge summary compared with 12 % in the intervention group. Medication omissions occurred in 17.33 % of discharges pre intervention compared with 14.67 % post intervention. Before the educational intervention, 28 % of discharge medications were sorted by disease compared with 65 % after. There was little improvement in the number of duplicate medications (18.67 % vs 17.33 %) or rates of pharmacy reconciliation (89.33 % vs 90.67 %).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

Medication Reconciliation is a complex process with many opportunities for intervention. A real time educational intervention with residents is time consuming and difficult to keep relevant for repeat learners. In our institution, we have residents from various programs, which makes timing of the intervention difficult. Our project suggests that the accuracy of discharge medication reconciliation can be improved, but it remains difficult to assess patient related outcomes such as satisfaction and medication safety. In addition, there are multiple systems issues that contribute to medication errors. These issues must be analyzed and addressed to truly impact change.

STAAR: IMPROVING THE RELIABILITY OF CARE COORDINATION AND REDUCING HOSPITAL READMISSIONS IN AN ACADEMIC MEDICAL CENTER Jocelyn A. Carter A. Carter; Gwen Crevensten. Massachusetts General Hospital, Boston, MA. (Tracking ID #1934428)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can innovations in healthcare delivery on a medical ward effectively reduce avoidable readmissions by improving care coordination for patients at risk for readmission?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) To reduce readmissions on the Ellison 16 medical ward (36-bed unit) to 10 % 2) To improve care coordination at discharge for patients at risk for readmission

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Initial measurement of Ellison 16 medical ward (a 36-bed general medicine unit) 30-day hospital readmission rates were less than ideal (18.3 %) prior to the interventions. The goal for readmission rate reduction to 10 % was set by an MGH Hospital-wide initiative. Staff education on readmissions (local and national landscape), survey of ward staff (physicians, nurses and unit managers) as well as on-site observations of discharge processes were completed prior to initiating the interventions. All patients admitted to the Ellison 16 medical ward were evaluated for inclusion from 07/2009–7/2013. If high risk criteria were met, patients were enrolled and received interventions which included care coordination with an inpatient discharge nurse (who provided education to patients/care givers, coached patients on their discharge care plan and served as a centralized navigator for the care team) and a discharge pharmacist (who facilitated medication reconciliation, counseled patients/caregivers on medication usage, and conducted post-discharge calls to patients). General interventions also occurred during this time period and

included reorganization of daily resident team rounding and discharge reconciliation processes.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1) All cause 30-day readmission rates using statistical process control analysis 2) Patient survey data tracking inpatient satisfaction and discharge experience satisfaction

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE $\ddot{\text{a}}\ddot{\text{e}}$ FINDINGS WILL BE DISCUSSED $\ddot{\text{a}}\ddot{\text{e}}$): 1) Overall, readmission rates on Ellison 16 decreased from 18 % (avr) before the interventions to 14.79 % (avr) after the interventions were implemented ($p<0.05$). 2) During the study period, the discharge nurse intervention decreased readmissions to 15.9 % amongst high risk patients ($p=0.59$). 3) During the study period, the discharge pharmacist intervention decreased readmissions to 12.9 % amongst high risk patients ($p=0.55$). 4) During the study period, post-discharge pharmacy calls demonstrated that 52 % of patients deviated from medication instructions after leaving the hospital. 5) During the study period, inpatient/discharge experience satisfaction did not change during the study. 6) Readmission rates for patients on Ellison 16 that did not receive the designated nursing or pharmacy interventions decreased to 15.8 ($p=0.61$) and 16.2 (0.31) respectively.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1) Reducing hospital readmissions on a general medicine unit is a complex process and requires input from physicians, nurses, case managers, patients and unit leaders. 2) Careful study of the processes of care and perspectives of key stakeholders is important in developing inpatient/discharge interventions. 3) While single interventions may not demonstrate statistically significant change in readmission rates, involvement of key stakeholders and awareness of readmissions as an organizational priority may effectively impact avoidable readmissions. 4) Patient satisfaction scores may not be impacted by care coordination improvements or reductions in readmission rates. 5) Additional studies are needed to validate inpatient/discharge nursing and pharmacy interventions in a setting of cultural change related to educating staff on readmissions.

STANDARDIZING THE DISCHARGE PROCESS WITH AN ELECTRONIC MEDICAL RECORD-BASED CHECKLIST - A RESIDENT-LED QUALITY IMPROVEMENT INITIATIVE Chapy Venkatesan; Nancy Maaty; Kimberly Lui; Shirley Kalwaney; Alita Mishra; Jillian K. Price; Yun Fang. Inova Fairfax Hospital, Falls Church, VA. (Tracking ID #1936879)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Prevention of avoidable readmissions and improvement of patient throughput are high priority initiatives, yet there is no standard discharge process for residents to follow.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Improve readmission rate and patient throughput for patients cared for by a teaching service. 2. Empower residents to lead quality improvement (QI) initiatives.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our QI team is located at a large community-based teaching hospital and consists of a 12 person transitional residency, two chief residents, and three hospitalist faculty physicians. All team members completed the IHI Open School QI modules. During the first team meeting, readmission prevention, improvement in hospital throughput, and the teach back technique were reviewed. The residents subsequently designed a best practice discharge process with a checklist in the electronic medical record. The intervention, enumerated in the checklist, consisted of 1) determining risk of readmission, using the Society of Hospital Medicine "The 8P's Risk Assessment Tool", 2) advanced notification and engagement of patients, families, and team members regarding discharge, 3) reminders to arrange early outpatient follow up appointments, 4) prompts to educate patients about their diagnosis and medications, and 5) in person resident-to-patient medication and diagnosis education using teach back. Residents were encouraged to perform the intervention for patients who were at high risk for readmission. When the intervention was completed, a final progress note with the checklist was generated and sent to the chief residents for record keeping. The QI team performed successive PDSA cycles with the goal of increasing the number of patients exposed to the intervention. The primary solution was to capitalize on the inherent competitive spirit of many of the interns by publicly displaying performance at morning report. "High performing" residents were able to advise their colleagues

on how to perform this intervention more efficiently. Patients cared for by the teaching service who were not exposed to the intervention during the same time period, served as a comparison group. Future PDSA cycles will focus on refining specific components of the intervention until readmission and throughput goals are met.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The QI team is tallying the number of interventions completed per week. Hospital administrative data is being utilized to determine 30 day readmission rates and will eventually be used to adjust outcome rates for differences in diagnosis, severity of illness, and other risk factors for readmission. Bed management data is being utilized to determine timing of discharge order and discharge time. Resident experience with the QI process and patient satisfaction with the intervention will be measured using survey instruments and focus groups. Direct observation using the University of Iowa "Teach-back Observation Tool" will be used to measure usage of the teach back technique and time spent during patient education. Finally, adherence to follow up and patient disease and medication knowledge will be assessed using patient questionnaires.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE $\ddot{\text{a}}\ddot{\text{e}}$ FINDINGS WILL BE DISCUSSED $\ddot{\text{a}}\ddot{\text{e}}$): A total of 254 patients were exposed to the intervention between September 2013 and December 2013. After resident performance was publicly displayed, the number of interventions per week increased from 7 per week to 19 per week. During October 2013, intervention data was available for 102 patients. This group of patients was at high risk of readmission. Forty-six patients (45 %) were aged 65 years or older, and 73 patients (72 %) were Medicare, Medicaid, or self-pay patients. Sepsis, pneumonia, heart failure, or GI hemorrhage was the primary discharge diagnosis in 78.4 % of patients. Thirty-two percent of patients reported a hospitalization within the prior 6 months, and 13 % were hospitalized in our own health system within the previous month. Nearly 20 % of patients were taking at least two high risk medications, and 65 % of patients met criteria for poly-pharmacy. The median case mix index (CMI) was 1.48. The comparison group, consisting of 331 patients, had a similar profile to the intervention group in terms of age, payor, and diagnosis. However, the median CMI was 14 % lower than in the intervention group. The 30 day readmission rate, within our five hospital health system, in the intervention group was 12.6 % versus a 15.4 % rate in the comparison group. The average time between discharge order and discharge time was 163 min in the intervention group versus 267 min in the comparison group.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Empowering residents to lead a QI initiative can be effective in improving use of an intervention. Pilot data suggests that following a standard discharge process, with a checklist embedded in an electronic medical record, can result in improvements in 30 day readmission rates and patient throughput.

SUCCESSFUL IMPLEMENTATION OF A LARGE SCALE HEPATITIS C SCREENING PROGRAM AMONG BABY BOOMERS IN AN URBAN PRIMARY CARE CENTER Lesley Miller¹; Shelly-Ann Fluker¹; Kristina L. Lundberg¹; Francois Rollin¹; Brandi Park¹; Kristi Quairol³; Anne Spaulding². ¹Emory University, Atlanta, GA; ²Emory University, Atlanta, GA; ³Grady Health System, Atlanta, GA. (Tracking ID #1937462)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The CDC and USPSTF now recommend one-time hepatitis C virus (HCV) testing for all baby boomers, however implementation of this large-scale screening in primary care practices, as well as linking newly positive patients to care, remain challenges that require innovative approaches.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The objectives of this CDC-funded demonstration project were to 1) Train internal medicine residents to implement birth cohort HCV antibody testing in their continuity clinics that serve an urban, medically underserved population. 2) Using residents as screeners, test 2,000 patients for HCV antibody over a one-year period, increasing the number of persons aware of their previously undiagnosed HCV infection. 3) Link HCV positive patients to onsite counseling, preventive services, care and treatment at the primary care-based, generalist-run Grady Liver Clinic or with their primary care providers.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The program was implemented in the Primary Care Center (PCC) at Grady Memorial Hospital (Atlanta, GA), an urban teaching hospital serving a primarily African American, medically underserved

population. The PCC has 58,000 patient visits annually. The first phase of the program was an educational intervention for all 147 internal medicine residents with continuity practices in Grady's PCC. Project faculty sent an email to residents describing the project structure and goals, and included teaching pearls supporting hepatitis C screening. Faculty followed up with one-on-one educational interventions for all residents during which a hepatitis C screening reminder was added to the electronic medical record template. Residents then proceeded with hepatitis C screening among patients in the 1945–1965 birth cohort during continuity visits. The project coordinator abstracted charts for results of HCV antibody testing, contacted all HCV antibody positive patients, and linked positive patients to an educational session followed by a physician visit at the Grady Liver Clinic. Patients with positive HCV antibody tests were sent for confirmatory HCV RNA testing.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We evaluated the success of each of the 3 program objectives by measuring 1) the number of residents reached with the educational intervention, 2) the number of patients who received HCV antibody testing and 3) the number of HCV antibody positive patients who attended a linkage to care visit. Data were collected over a 1 year period on the total number of HCV antibody tests ordered and drawn, the number of patients testing positive for HCV antibody, HCV RNA and presenting for a linkage visit.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *â€œFINDINGS WILL BE DISCUSSEDâ€*): At the end of the first project year, 147 residents (100 %) had received the educational intervention and had screened 2,439 PCC patients for HCV antibody, well over the 2,000 tests predicted. Of the 2,439 screened, 190 (7.8 %) tested positive for HCV antibody. Of the antibody positive patients, 149 (78 %) were tested for HCV RNA. Of these 149 with HCV RNA results, 104 (70 %) were RNA positive, confirming chronic HCV infection. Of the 104 with confirmed HCV infection, 96 % followed up with an internist, either with their PCP or at the Grady Liver Clinic.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Large scale implementation of new hepatitis C screening guidelines was feasible in a resident primary care practice and yielded an unexpectedly high prevalence of HCV infection that was previously undiagnosed. We achieved very high rates of linkage to care for HCV antibody positive patients, and all linkage was to general internists, whether in our primary-care based Liver Clinic or with primary care providers. It is likely that testing in similar populations would yield an equally high prevalence of undiagnosed hepatitis C, a compelling reason to screen. Our model suggests that generalists can become adept at initial, and if interested, in-depth hepatitis C care to manage patients identified through screening.

THE AFFORDABLE CARE ACT: HELPING PATIENTS SIGN UP FOR HEALTH COVERAGE THROUGH THE MARKETPLACE Sita Bushan¹; Robin H. Roche^{2,1}; Shana Ratner¹. ¹University of North Carolina- Chapel Hill, Chapel Hill, NC; ²AccessCare, Morrisville, NC. (*Tracking ID #1938430*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Nearly 2000 uninsured patients in our clinic needed assistance with and education about the Affordable Care Act (ACA).

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To assess patient interest in assistance with signing up for the Affordable Care Act To educate both patients and providers about the Affordable Care Act To pilot a Saturday Sign Up Day to assist patients with signing up outside of regular clinic hours

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): UNC Internal Medicine Clinic (IMC) is an academic general internal medicine practice in North Carolina, a state which did not expand Medicaid. About 20 % of our patients are currently uninsured. Patient surveys were given to uninsured patients at clinic to assess the demand for assistance with signing up for the Marketplace. We developed educational materials in both English and Spanish for our patient population, including lists of local community resources, and provided education to staff through presentations and emails. A front desk-prompt was developed to direct uninsured patients to our financial counselor. Three clinic members trained to become Certified Application Counselors (CACs). We collaborated with UNC School of Medicine and Legal Aid to recruit CACs and Navigators to pilot a Saturday Sign Up Day where patients could meet with a CAC to enroll in marketplace, explore their options, and sign up for health insurance. After

determining patient satisfaction with the Saturday Sign Up Day, we are planning a larger scale enrollment event in January.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Patient surveys were collected to assess demand for assistance. Data collected from the pilot Saturday Sign Up Day included number of appointments and walk-ins, number of no-shows for appointments, number of applications filled out, other social needs to address, and barriers to obtaining health insurance.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *â€œFINDINGS WILL BE DISCUSSEDâ€*): Twelve surveys of uninsured patients were collected, and 11 of these patients had not completed the application for the Health Insurance Marketplace. Most patients expressed interest in receiving help at the clinic. The Saturday Sign Up Day pilot offered 15 appointments, 100 % of which were scheduled. Fourteen patients completed appointments (9 scheduled, 5 walk-ins). Half completed an application (7/14). The most common barrier to obtaining health insurance was income level that caused patients to fall in the coverage gap between Medicaid and Qualified Health Plans. Staff also assisted patients in obtaining Medicare Part D coverage, applying for Medicaid, and obtaining information about food stamps. Education of staff members about the ACA resulted in 15 referrals to the Saturday Sign Up Day. A larger scale event is being planned in January for 120 patients, utilizing lessons learned from the pilot sign up day. Booths from local social service groups will be available to assist patients with other social needs.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Assistance with the ACA application in the clinic setting encourages patients to apply. Events like the Saturday Sign Up Day represent one method of providing assistance to patients that bypasses space and time constraints of the regular clinic day. Assisting patients with the ACA offers opportunities to help with other social services such as medication coverage, Medicaid, and food stamps.

THE CARE PROJECT: A MULTI-DISCIPLINARY APPROACH TO IMPROVE THE CARE OF HOSPITAL SUPER-UTILIZERS Saraswati R. Iobst¹; Kelly Berchou¹; Kristin Muzina²; Caroline Hoppenheim²; Riya George¹; Celine Goetz¹; Katie Salib²; Yvette Rolon-Fink²; Carol DeJesus². ¹New York Presbyterian Hospital/Weill Cornell Medical Center, New York, NY; ²New York Presbyterian Hospital/Weill Cornell Medical Center, New York City, NY. (*Tracking ID #1934712*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Hospital super-utilizers often receive inadequate care despite exorbitant costs incurred to the medical system; a multidisciplinary team that focuses on an individualized approach to care has been demonstrated in the literature to improve care and reduce costs in this patient population.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Our primary aim is to decrease annual inpatient admissions among hospital super-utilizers by an average of 30 % over a 12-month period. We also aim to perform in-depth assessments of each enrolled patient to identify barriers to care and unmet needs contributing to frequent hospitalizations; and based on this assessment, to develop individualized intervention plans that can be qualitatively measured for success. For example, if we identify lack of stable housing as a barrier, then obtaining stable housing would be a measure of success.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our program, entitled the CARE Project, focuses solely on hospital super-utilizers and is the first of its kind at Weill Cornell Medical Center. We have created a multi-disciplinary care team comprised of representatives from hospital medicine, social work, primary care, and emergency medicine. We are using a community-based model, meaning we follow patients in both the inpatient and outpatient setting. We have defined a hospital super-utilizer as a patient with five or more inpatient admissions to the Medicine service within a 12-month period. We plan to enroll a total of 10 patients over a 12-month pilot period. After initial engagement with a patient, we perform an in-depth needs assessment to identify barriers to care and unmet needs contributing to frequent hospital admissions. Based on our findings, we create an individualized care plan in collaboration with the patient, caregivers, and providers. Many of our interventions are directed towards unmet psychosocial needs as well as facilitating care coordination and communication between providers as well as between providers and patients.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/

INTERVENTION: We will compare the following variables from the 12 months prior to project enrollment to the 12 months after enrollment for each patient: number of admissions to the general medicine service; number of 30-day readmissions; average length of stay (LOS) per admission; number of ED visits; and cost data (hospital charges vs. actual reimbursement). We will also qualitatively assess the outcome of each patient's individualized intervention plan.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): We have thus far enrolled 4 patients; enrollment is ongoing. Below are brief descriptions of our first 2 cases: Patient 1: 67 year-old man with congestive heart failure (CHF) who has been admitted to our hospital ten times over the past year for CHF exacerbations. He had not been to his PMD or cardiologist for almost 2 years. After 1 month of intensive engagement, he revealed that he was undomiciled. In addition, he was developing blindness from severe cataracts. Our initial intervention plan included re-establishing care with a primary care physician. He also underwent successful cataract surgery, which required obtaining temporary housing and significant care coordination. The most critical remaining goal of our intervention plan is to obtain permanent housing. Patient 2: 34 year-old man with sickle cell anemia complicated by severe iron overload and Mediport colonization leading to recurrent bacteremia and frequent admissions for sickle cell pain crises. He has had seven hospitalizations over the last 12 months, averaging 33 days each. As he is frequently hospitalized, we have become his support network in the hospital, visiting with him frequently. We have successfully coordinated care with his inpatient providers and have succeeded in having his Mediport removed. We have also arranged an appointment with a multi-disciplinary sickle cell anemia clinic that has access to outpatient infusion capabilities and active pain medication management. We also have obtained insurance approval for outpatient chelation therapy.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. As the current healthcare system is fragmented and often ineffectual in caring for super-utilizers, a commitment to innovation and clinical re-design is crucial to any program that aims to improve care in this patient population. 2. Engage stakeholders early and continuously. Stakeholders need to be from both the outpatient and inpatient settings, as well as multi-disciplinary. 3. As these patients often have significant psychiatric comorbidities, partnering with a psychiatrist is crucial. 4. We have found assisting these patients to be a very time intensive process. They require ongoing psychosocial support and help navigating a complex, fragmented system. Much of our initial work is spent engaging patients and relationship building. 5. Hospital super-utilizers represent a diverse group in terms of diagnoses and underlying problems leading to over-utilization of hospital resources, which is why a highly individualized approach is critical.

THE MAGIC DESK PROJECT: REDESIGNING THE DESK IN THE CLINIC EXAM ROOM Ira Helenius¹; Daniel Becker^{1,2}; Sarai C. Martinez-Suazo¹; Reuben M. Rainey²; Roger C. Sherry²; Theo Van Groll²; Natalie May¹. ¹University of Virginia School of Medicine, Charlottesville, VA; ²UVA School of Architecture, Charlottesville, VA. (*Tracking ID #J928402*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In the presence of the electronic medical record [EMR], do desk shape and computer/printer position influence clinician-patient interactions and clinic visit satisfaction?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) reduce the temptation to stare at the EMR while talking and listening to the patient; 2) collaborate with architects, furniture designers, and craftsmen to redesign the clinic desk, improve access to the computer screen, and reorganize the space around the desk; 3) to determine if these changes affected the patient-clinician interaction during a regular office visit .

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): With a health and design grant from the School of Architecture and an internal grant from the Division of General Medicine, we conceived, designed, built, and installed the "magic desk" in an exam room at an internal medicine clinic. This desk is a curved wooden platform that is anchored to the wall, appears to float in place, and makes it easier for the patient to share the computer screen with the doctor or nurse. It has a built in swivel for moving the screen in or out of view, per HIPPA restrictions. For images see: <http://uvadesignhealth.org/docs/news/fellow-project-eye-contact-in-exam-rooms>.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): In order to determine the effect of the desk on the clinical

encounter we designed a survey for patients and one for doctors. Patients were randomly assigned to be seen by their regular physician or nurse practitioner in either the redesigned room or in the standard room. The standard desk was a sheet metal desk with square corners and stationary computer screen. After the visit the research assistant asked patients if they felt the EMR was good for their health care, whether their doctors looked at them more than the computer, seemed interested in listening to them, shared EMR information with them, and spent enough time with them. Doctors were surveyed at the end of each session and asked if being in the redesigned room made it easier to listen to patients, maintain eye contact, and finish the note during the visit. We also asked if the doctors preferred one room to the other.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE â€œFINDINGS WILL BE DISCUSSEDâ€): The study was conducted in the summer of 2013. There were 43 study room patients, 36 standard room patients, 11 attending physicians, 1 nurse practitioner. One patient refused to complete the after visit survey. All patients were at clinic for routine follow-up visits. There were no significant differences in the demographics of the two groups of patients: each group had slightly more women than men, slightly more white than non-white patients, and approximately half the patients were older than 50 years. The length of the doctor patient relationship was also similar in the groups: approximately 25 % knew the doctor longer than 5 years. Comparison of the patient survey results from the patients seen in the redesigned room versus those seen in the standard room showed no significant differences. Almost without exception patients felt the EMR was good for their health care. Regardless of the room, almost all patients felt their doctors looked at them more than the computer, spent enough time with them, and were interested in their stories. In general, these patients were highly satisfied with their doctors and their care. Results of the doctor survey showed that in 75 % of the sessions, the doctors preferred the redesigned room to the standard room. Eighty percent of the time they felt that the redesigned room made eye contact easier. The redesigned room did not make it easier to listen; nor did it improve efficiency. As pretty as the desk is, moving the printer out of the way also made a lasting positive impression on the doctors working in that room.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): This collaboration helped us rethink and reimagine the space and information we share with our patients. Although the magic desk and the design changes that came with it did not make a measurable difference in doctor-patient interactions or patient satisfaction, the doctors preferred it and noted that it reminded them to share the EMR and then made it easier to do so. Perhaps the patients were already so pleased with their doctor that re-designing access to health information did not have an easily measurable impact.

THE PROJECT RED CHIP (REDUCING DISPARITIES AND CONTROLLING HYPERTENSION IN PRIMARY CARE) CARE MANAGEMENT INTERVENTION: AN EVALUATION OF ITS EFFECTIVENESS & IMPLEMENTATION Tanvir Hussain^{1,2}; Whitney K. Franz^{2,4}; Emily L. Brown^{2,4}; Kara Taylor^{2,4}; Mekam T. Okoye²; Arlene Dalcin²; Kathryn A. Carson³; Katherine Dietz²; Jennifer Halbert²; Romsai T. Boonyasai^{1,2}; Jill A. Marsteller^{2,3}; Lisa A. Cooper^{1,2}.

¹Johns Hopkins University School of Medicine, Baltimore, MD; ²Johns Hopkins Center to Eliminate Cardiovascular Health Disparities, Baltimore, MD; ³Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ⁴Johns Hopkins HealthCare LLC, Baltimore, MD. (*Tracking ID #J939834*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Proliferation of care management (CM) programs for chronic disease care, despite mixed effects, urges deliberate evaluation of the implementation components that predict success.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To evaluate the effectiveness of CM in improving blood pressure (BP) and reducing hypertension (HTN) disparities in primary care. 2. To describe implementation of a CM intervention and inform the design of future programs

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Developed using a community-based participatory approach, our CM program invites HTN patients ≥ 18 years with uncontrolled BP ($\geq 140/90$) within the last 6 months to participate in 2 h of in-person CM—first session 1 h, followed by two half-hour sessions, over 3 months. Registered Dietitians (RDs) and Doctors of Pharmacy (PharmDs) trained in motivational interviewing educate patients about HTN and encourage adherence to medications, DASH diet, physical activity, and self-monitoring behaviors; patients with BP $\geq 160/$

100 preferentially see PharmDs to focus on medication adherence. The intervention is being implemented across six clinic sites in Baltimore, three of which care for underserved populations. Now completed at clinic 1 (inner city, underserved site), the intervention is underway at clinics 2 and 3.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. BP improvement 2. Adoption rates (% enrolled, % completing intervention) 3. Patient satisfaction

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *â€œFINDINGS WILL BE DISCUSSEDâ€*): Adoption: Of 897 eligible at clinic 1, we contacted 509 (57 %) patients. Of the 319 scheduled, 175 (55 %) completed session 1 and 65 (20 %) completed all three sessions. Fidelity: Mean BP of patients ($n=155$) starting with RDs was lower than expected, 135/80; however, patients continued the program given the variable nature of BP. For those ($n=20$) starting with PharmDs, mean BP was 153/90. Average total contact time was 149 mins. (Data for clinics 2 and 3 will be available in Spring 2014.) Patient Acceptability: Among patients completing all three sessions across the three clinics to date ($n=100$), 35 (65 %) patients responded to the post-intervention patient experience survey. Sixty-three (97 %) respondents reported ideal session length is at least 30 mins. Forty-one (63 %) wanted more sessions. Thirty-three (56 %) would have found the addition of phone sessions helpful; email, text messages, and online support were viewed less favorably. Two-thirds responded that education on taking medications, following a DASH diet, reading food labels, and exercise were each very helpful in controlling BP; half reported that weight loss and BP self-monitoring education were very helpful. Effectiveness: BP control data are pending. Among our survey respondents, mean reduction in individual systolic BP and diastolic BP was 5.4 mmHg (SD=16.9) and 4.5 mmHg (SD=9.7), respectively, between sessions 1 and 3. BP improvement was associated with trust in care managers, medication adherence, developing a BP treatment plan the patient could carry out in daily life, and patient confidence to actually do the things needed to take care of one's BP.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Integrating CM programs into clinical settings is challenging. Seeking provider and staff input during the design phase, encouraging CM telephone outreach to and physician referral of eligible patients, and allowing local adaptation of the intervention can enhance adoption. Patients are highly satisfied with care managers and value disease education and behavior change support. Preliminary results suggest developing a realistic patient treatment plan and increasing self-efficacy through CM will help improve BP.

TRANSFORMING CARE TRANSITIONS: IMPLEMENTING PROJECT RED AT A VETERANS AFFAIRS MEDICAL CENTER Melissa Bachhuber^{2,1}, Jeanette Broering^{3,1}; Christine Welles⁴; Margaret Wallhagen⁵. ¹San Francisco VA Medical Center, San Francisco, CA; ²University of California San Francisco, San Francisco, CA; ³University of California San Francisco, San Francisco, CA; ⁴University of Colorado, Denver, CO. (*Tracking ID #1937156*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The San Francisco Veterans Affairs Medical Center data demonstrate that Veterans over age 65 have 16.8 % and 28.6 % 30 and 90 day all-cause readmission rates, respectively. Comprehensive strategies to reduce readmissions are needed.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To implement the evidenced-based transitional care model, Re-engineered Discharge (Project RED) on the inpatient medicine service for high risk Veterans in order to reduce 30 and 90 day all-cause hospital readmissions.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Five Project RED nurse care coordinators were assigned to each inpatient medicine team at a Veterans Affairs Medical Center. Care coordinators followed medicine inpatients based on high risk criteria including: Age >65, >10 medications, homeless status, substance abuse or mental health comorbidity, living alone, no assigned PCP, prior hospitalization within past 90 days, >3 ER visits in 6 months, and admission diagnoses including CHF, pneumonia, or ischemic heart disease. Care coordinators provided comprehensive discharge planning, care coordination, and after hospital care plans to high risk patients. Providers including pharmacists, physicians, social workers, clerical staff, and outpatient primary care teams had designated roles in completing components of RED such as medication reconciliation, handoff communication, telephone follow up, and appointment scheduling.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Primary outcome measures include 30 and 90 day all cause readmissions for patients receiving the Project RED intervention. Seven process measures of transitional care will be analyzed by chart review including medication reconciliation, electronic handoff note to primary care team, post-discharge phone call within 48 h, discharge summary completed within 48 h, follow up appointment within 14 days scheduled and attended, and after hospital care plan provided to patient. Length of stay will be followed as a balance measure.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *â€œFINDINGS WILL BE DISCUSSEDâ€*): A total of 726 Veterans from the inpatient medicine service received the Project RED intervention from December 2012 to July 2013. Two hundred and thirty three (32 %) electronic medical records were randomly selected for review. Seven were excluded due to death during hospitalization or leaving against medical advice. Veterans acted as their own control for history of hospitalization prior to receiving the intervention. Veterans were on average 69 years-old (± 12); 97 % male; 37 % with mental health comorbid condition; and 22 % with poly substance abuse. Forty three percent of Veterans had been previously hospitalized within 30 days of participating in the Project RED intervention. Post-intervention 30 day and 90 day readmissions were 20 % and 31 % respectively. Average length of stay was higher among PR recipients (8.7 versus 5.4 days) when compared to all Veterans admitted from December 2012 to July 2013. Process measures (target goal versus actual achieved) were: Medication reconciliation (100 % vs. 90 %); electronic handoff note to primary care team (80 % vs. 72 %); Veteran reached by phone call follow-up within 48-hours (95 % vs. 81 %); discharge summary completed within 48-hours (80 % vs. 83 %); 14-day follow-up appointment scheduled (90 % vs. 69 %); 14-day follow-up appointment attended (80 % vs. 55 %); after hospital care plan in place (80 % vs. 51 %).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Early data suggests RED implementation at a Veterans Affairs Medical Center may be successful in reducing 30 and 90-day readmissions among high risk Veterans. Role clarity for providers involved in each component of the intervention (physicians, pharmacists, nurse care coordinators, social workers), coordination of follow-up care, and timely creation of the after hospital care plan are important considerations for successful implementation. The electronic medical record was instrumental to communication of the electronic handoff and discharge summary to the primary care team. Given the complexity of the intervention, multidisciplinary leadership support within the organization is needed for implementation.

WHY DO OUR PATIENTS REALLY GET READMITTED? COMPARING THE DISCHARGING PHYSICIAN AND PATIENT'S PERCEIVED REASONS FOR HOSPITAL READMISSION Monica Reynolds; John M. French; Jonathan Kirsch; Beth Ann Brubaker; Edmund A. Liles. University of North Carolina, Chapel Hill, NC. (*Tracking ID #1939323*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): If discharging physicians are not informed of their patients being readmitted, it can be difficult to know the reasons and learn from our patients experience.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Assess impact of real time feedback from both patient and attending physicians on readmission preventability and causes 2. Compare perceptions of the reason for a readmission between discharging physician and the readmitted patient

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We present an observational study in a large academic medical center assessing the opinions of patients and physicians on whether hospital readmissions are preventable. While many studies on readmissions prevention focus on close follow-up appointments, post-discharge phone calls and bundled programs, there is a paucity of literature utilizing real-time patient and physician feedback for insight. In 2012, the Centers for Medicare and Medicaid Services defined readmission criteria and measures under the Hospital Readmissions Reduction Program (HRRP). It is often difficult for a physician to know if a patient gets readmitted within 30 days and feedback from these patients is generally difficult to obtain, though we believe that we can learn from these patients and possibly reduce future readmissions. We established a real-time system for alerting the discharging physician of a readmission so we could learn from our patients. Discharging physicians were provided real-time feedback of readmissions through daily emails

with patient's medical record number. They were then responsible for performing a chart review adapted from the Institute for Healthcare Improvement STAAR Initiative. Physicians were asked to comment on social conditions or mental illness that could have contributed to the readmission and to discuss what should be done to prevent future readmissions. Patients were in turn interviewed during their readmission and asked questions regarding prior discharge instructions, medication compliance, follow-up appointments/phone calls and overall support once outside the hospital. They were also asked to comment on whether they believed this readmission was preventable and ways to prevent a future admission.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Prior to these notifications and chart reviews and again after 6 months, physicians were surveyed on their perception of readmissions in general and their preventability. Outcomes of interest were 30 day readmission rates, physician and patient perspectives and estimates of preventability. The notifications and chart reviews began July 1, 2013 and are ongoing.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE *“THE FINDINGS WILL BE DISCUSSED”*): Of 15 patients interviewed, 13 of 15 stated they were able to take their discharge medications as prescribed. However, the two remaining felt that the one intervention to prevent their readmission was directly related medication compliance. Thirteen of 15 did not find discharge instructions confusing or hard to interpret. Thirteen of 15 felt that they had proper support once leaving the hospital with the majority citing family members as their primary support. Only 5 of 15 were able to follow-up with a primary care physician. However, 10 of 15 did receive follow-up phone calls from either a hospital RN or MD. Overall, 13 of 15 patients interviewed felt the readmission was not preventable. As a whole, most patients believed they were prematurely discharged before their medical condition was fully treated or diagnosed. This was related to pain management in 4 of 15 patients and an unclear diagnosis at discharge in 3 of 15 patients. Based on initial attending physician survey, 13 % of attending physicians felt less than 10 % of readmissions were preventable but this increased to 30 % after 6 months of timely notification and chart reviews. At baseline, the top three contributors to readmissions were felt to be patient understanding, medication non-adherence, and substance abuse/addiction. After 6 months of the intervention, the top three contributors were felt to be substance abuse/addiction, medication non-adherence and lack of primary care.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Surveying physicians and interviewing readmitted patients in real-time may allow for expedited root cause analysis of the readmission and eventually lead to a reduction in all cause readmission rates. Overall, 87 % of patients felt their readmission was unavoidable. Physician chart review indicated that medication adherence was a major concern but in contrast 87 % of patients stated they did not have trouble taking their medications. Close follow-up was also a concern for physicians and indeed only 33 % of patients endorsed visiting a primary care physician. To prevent readmissions, patients believed they should be included in discussions regarding discharge readiness and final discharge diagnosis.

INNOVATIONS IN MEDICAL EDUCATION (IME) “MS. B CHANGES DOCTORS”: USING A COMIC AND PATIENT TRANSITION PACKET TO ENGINEER PATIENT-ORIENTED CLINIC HANDOFFS (EPOCH) IN A RESIDENT CONTINUITY CLINIC Amber Pincavage¹; Wei Wei Lee¹; Laura Ruth Venable¹; Megan Prochaska¹; Daina Stasiunas¹; Kimberly J. Beiting²; M. K. Czerwic³; Vineet Arora¹. ¹University of Chicago, Chicago, IL; ²University of Illinois at Chicago, Chicago, IL; ³Northwestern University, Chicago, IL. (*Tracking ID #1940083*)

NEEDS AND OBJECTIVES: While patients are especially vulnerable as they transition during the year-end clinic handoff, patient input to improve the resident clinic handoff process has been lacking. The aim of this study was to implement and assess the impact of a patient-centered transition packet and clinic handoff comic on patient-centered handoff outcomes.

SETTING AND PARTICIPANTS: This study took place at one urban academic internal medicine residency continuity clinic at the University of Chicago. High-risk clinic handoff patients were identified by departing residents and asked to participate in interviews.

DESCRIPTION: To create a patient-centered process, we interviewed over 100 patients shortly after their transition for suggestions in 2011. Using this input, 2 months before the 2012 handoff, patients were sent a “transition packet” with a goodbye letter form the

departing resident, a welcome letter from the new resident with their picture and personal information (i.e. hobbies), a certificate of teaching recognition, and a visit preparation tool to improve communication with the new PCP. In 2013, a patient comic was created to boost recall of the packet, draw attention to the packet and educate patients about the clinic handoff called, “Ms. B Changes Doctors.” In 2012 and 2013 (post-packet), patients were interviewed by phone on the impact of the packet on: awareness of the transition, ability to correctly identify the primary care physician (PCP) after the handoff, and satisfaction with the handoff. Patient outcomes (number of patients missing their first visit with their new PCP) were determined by performing chart review. Likert scale questions and outcomes were summarized descriptively and compared using chi square tests and trend analysis for proportions where appropriate. The 2011 cohort of patients (who did not receive the packet) served as a control group.

EVALUATION: Interviews were conducted with 103 patients in 2011, 113 in 2012 and 107 in 2013. The majority of patients after the packet were aware of the clinic handoff (99 %, 103/113 in 2012 vs. 99 %, 106/107 in 2013). Half (44 % 50/113) of the patients interviewed in 2012 recalled receiving any part of the transition packet, however, this increased with the patient comic in 2013 (64 %, 69/107, $p<0.001$). The number of patients able to correctly identify their PCP increased after the comic was added (77 % 87/113 in 2012 vs. 98 % 105/107 in 2013 $p=0.002$). Out of the patients who recalled the transition packet, the majority of them agreed (70 %, 19/27 in 2012 and 65 %, 45/69 in 2013) the information helped them build a relationship with their new physician and the packet helped them prepare for their first visit with their new physician (70 %, 18/26 in 2012 and 67 %, 46/69 in 2013). Of those who recalled the comic during the interview, 87 % (26/30) thought the comic was helpful and 60 % (18/30) agreed the comic helped prepare them for the transition. Lastly, there was a decrease in the percentage of the number of patients who missed the first visit with their new physician from pre-packet to post-packet (43 %, 139/323 in 2011 vs. 31 %, 82/264 in 2012 and 26 % 70/273 in 2013, $p<0.001$). When asked about the welcome letter she received one patient commented, “It was nice because it gives the patient the chance to see and know something about the new doctor they're going to be meeting.” Another patient reported it “made her look forward to her first appointment.” Another patient when asked about the certificate of recognition stated, “it was cute and acknowledged me and made me feel appreciated.” Another patient reported, “it's on my wall!” When asked about the comic, one patient responded, “it was cute and it stood out: it's what made me call in and make an appointment.” Another patient thought it was “funny and informative.” One patient thought the visit tool was “informative and helped me ask certain questions”, while another thought it was a “great opportunity for the new PCP to learn about me right away.”

DISCUSSION/REFLECTION/LESSONS LEARNED: A patient-centered clinic handoff was helpful to patients and may have encouraged patients to return for care after the handoff. The comic may have increased transition packet recall while both the comic and the packet was effective and helpful to patients.

A DECADE OF CHANGE IN ATTITUDES TOWARD THE HOMELESS AMONG PRIMARY CARE INTERNAL MEDICINE RESIDENTS Frances Norlock; Laura Sadowski; Meghan Kapolnek. Stroger Hospital of Cook County, Chicago, IL. (*Tracking ID #1939203*)

NEEDS AND OBJECTIVES: The prevalence of homelessness is increasing. Few resident programs offer formal training in how to provide care for the homeless. Educators implemented a homeless medicine rotation to decrease residents' stigma associated with homelessness and improve the clinical care resident physicians provide to homeless patients. Investigators wanted to assess the difference in attitudes toward homelessness between primary care internal medicine (PCIM) residents over the past decade (2002 and 2012). It was hypothesized that the 2012 cohort would have less prejudice towards the homeless prior to the rotation and less of a change in stigma score. This was supported by the passing of the Affordable Care Act (ACA) in 2010 and increased funding for programs that support underserved populations; the recent financial crisis of 2008 which may be viewed by residents as an external cause of homelessness; and the impact of social media since 2003 and potential positive informational effect it could have had on the 2012 residents.

SETTING AND PARTICIPANTS: PCIM residents participated in a 2 week homeless medicine rotation based at an urban, public hospital focused on collaborating with partners in the community. Residents participated in group seminars on campus and engaged in tours and clinical experiences in the community, including working with patients in shelters, clinics and residential housing programs.

DESCRIPTION: Curriculum consisted of small group seminars on epidemiology, chronic disease management and lifestyle issues affecting health outcomes in the homeless. Learners worked in community-based clinics that served the homeless and were assigned evening shifts to care for those in shelters with medical issues as well as facilities where women and children resided. Residents' attitudes were assessed pre- and post-rotation using an 11 item Attitudes Toward Homelessness Inventory

(ATHI) consisting of 4 subscales which attribute homelessness to societal cause; personal cause; having a willingness to affiliate with the homeless; and belief that homelessness is a solvable problem. A higher summation score of the 4 subscales equates to improved attitudes and lower stigma of homelessness. A meaningful difference score of 5.5 was set a priori.

EVALUATION: The 2012 cohort ($n=12$) had a pre-rotation mean summation score of 42.0 compared to 45.4 in the original cohort ($n=18$) indicating less stigma a decade ago prior to the onset of the rotation (although the mean difference of 3.4 was not meaningful). Post-rotation the mean summation score was 46.8 in 2012 compared to 51.7 decade earlier with an improvement in mean change score of 5.0 and 6.3, respectively. The 2012 cohort's total sum mean change score of 5.0 was in the positive direction and was close to the meaningful change criteria of 5.5. The greatest increases in mean change scores for 2012 were for societal cause (1.67) and affiliation (1.67); a decade earlier the greatest mean change score was 3.0 for the societal cause subscale.

DISCUSSION/REFLECTION/LESSONS LEARNED: Residents had lower stigma towards the homeless at the onset of the rotation in 2002 compared to current residents as well as a greater improvement in attitude and lower stigma toward the homeless. These findings may be due to an unknown variation in the demographic composition between resident cohorts as well as possible variation in the educational didactic and clinical experiences a decade later.

A MEDICAL SPANISH ELECTIVE WITH A SPECIAL EMPHASIS ON LINGUISTIC HUMILITY Cristina M. Gonzalez¹; Yovana Q. Coupey²; Maria A. Marzan²; A. Hal Strelnick². ¹Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY. (Tracking ID #1938843)

NEEDS AND OBJECTIVES: More than 10 % of the US population has limited English proficiency (LEP). Medical students will be caring for these patients, yet there are few medical language programs described in the literature. Our objective is to describe a medical Spanish elective highlighting enhancements made and lessons learned.

SETTING AND PARTICIPANTS: First and second year students at Albert Einstein College of Medicine in Bronx, NY.

DESCRIPTION: This lunch-time elective meets 16 times for 1.5 h a session in the first semester and 12 sessions in the second. Its goal is to increase students' ability to communicate in Spanish in a clinical setting by focusing on conducting a medical interview in a linguistically effective and culturally appropriate manner. Students are placed in one of six levels according to an oral assessment directed by an instructor in conversational Spanish. The instruction for each level is tailored to those learners. Recently three enhancements occurred. Students practice interviewing community volunteers (real patients). We have hired professional Spanish language instructors trained in medical terminology and patient-centered history taking. There is also a strong emphasis on linguistic humility. Students interview real patients and practice linguistic humility by learning how to recognize their own limitations and bring in and work effectively with an interpreter (first four levels) or develop strategies to seek clarification from their patients (advanced two levels). Students are assessed via a final interview, written exam, homework assignments, and attendance. Grading rubrics developed by the instructors for the final interview focus on accuracy, coherence, creativity, and vocabulary. During the final interview, students interview a standardized patient (SP) with an interpreter (if needed). The Spanish instructor, SP, and interpreter (if needed) each assess the student's performance. Students must attend at least 80 % of the sessions in order to sit for the exam and pass the course.

EVALUATION: In the first cohort, 84 first-year students registered with 75 % attending 80 % or more classes, 100 % of whom passed the course (score range 92–96 %). A total of 29 s-year students returned for the second semester, with 19 attending 80 % or more of the classes, 100 % of whom passed the course (score range 89–100 %). The second cohort of students had 97 first-year students register for the course, with 74 attending 80 % or more classes, 100 % of whom passed the course (score range 88–97 %). Second semester grading is underway. Students rated the areas of instruction that were most useful. The most frequently cited strengths were the interviews with real patients, as opposed to SP, and their instructors. The most cited change would be to include more instruction in grammar earlier in the course.

DISCUSSION/REFLECTION/LESSONS LEARNED: The three enhancements to the course positively impacted the students' experience. Students early in their medical school experience are excited to speak to real patients. This may be a way for programs to attract participants. Our experience also lends support to making the investment in professional language instructors trained in medical interviewing.

Finally, an emphasis on linguistic humility is important, as there have been reports of decreased interpreter use after a brief period of Spanish language instruction, when an interpreter was actually needed. The use of professional interpreters or bilingual providers improves the quality of care for patients with LEP thereby reducing disparities.

A MODEL SEMINAR FOR PRECLINICAL HEALTHCARE SAFETY AND QUALITY INSTRUCTION John R. Joseph; Huixia Wei; Vahid Pasovic; Caitlin Biedron; Amy Li; Diane L. Levine. Wayne State University School of Medicine, Detroit, MI. (Tracking ID #1939503)

NEEDS AND OBJECTIVES: The importance of incorporating patient safety and quality improvement topics in undergraduate medical education is evidenced by the American Association of Medical Colleges (AAMC) recommendation to integrate these concepts as early as the first year of medical school. Efforts are presently underway to recognize important attributes students should possess at graduation from medical school called "Core Entrustable Professional Activities for Entering Residency" (CEPAER). Among these activities is the ability to identify system failures and contribute to a culture of safety and improvement. The Wayne State University School of Medicine student chapter of the Institute for Healthcare Improvement (IHI), with support from school administration, set to increase exposure to these topics for preclinical students by hosting a voluntary patient safety seminar.

SETTING AND PARTICIPANTS: The seminar was held in school facilities on a Saturday morning. It was offered as one option to fulfill a requirement for a Saturday seminar through the school's Co-curricular Program for which students commit to 75 h of community service and 75 h attendance at educational lectures which may be used for credit for 1 month rotation during student's fourth year. The seminar was open to the entire student body and advertised through school-wide emails and poster displays.

DESCRIPTION: The seminar began with an introduction to basic safety and quality principles. Next, students split into six groups and rotated through three different breakout activities lasting roughly 30 min each. These included a discussion on human factors engineering, a case study in infection control, and an interactive activity highlighting teamwork and communication. Each session was facilitated by a volunteer faculty whose clinical practice includes formal safety or quality responsibilities (i.e. Assistant Chief of Quality and Safety). The small group sizes of roughly 17 students and interactive design of activities/discussions fostered good discussion and provided an intimate setting for questions and comments. The seminar ended with a summary of the current state and future directions of healthcare safety and quality delivered by a former chief quality and safety officer of a local medical center.

EVALUATION: A total of 104 students and 6 faculty facilitators participated in the seminar. The seminar lasted 2.5 h in total. Identical surveys were distributed before and after the event for purposes of evaluating changes in knowledge and attitudes towards safety and quality. The initial survey was completed by 86 students (83 % response rate) and the post-seminar survey by 79 students (76 %). The responses were aggregated and analyzed. Five multiple-choice questions evaluated knowledge related to safety and medical errors. Student's knowledge increased on all questions. The remaining 15 questions evaluated knowledge as well as attitudes towards safety and quality using a 5-point Likert scale (1 = Strongly Disagree to 5 = Strongly Agree). Students showed improvement in 13 of 15 questions as evidenced by movement of the mean towards the desired response. The seminar was very well received with all respondents indicating the seminar was good to excellent.

DISCUSSION/REFLECTION/LESSONS LEARNED: A voluntary seminar is an effective way to introduce medical students to key concepts in patient safety, quality and quality improvement techniques. The event was well received by preclinical students and survey data revealed an increase in knowledge and improvement in attitudes towards safety and quality immediately following the event. The majority of students indicated that they would like to see similar content added to the formal medical curriculum. The incorporation of smaller breakout sessions led to challenges in logistics and planning, including finding additional qualified faculty volunteers. The smaller groups and interactive activities were very well received by students and facilitators, however, and the authors recommend this strategy over traditional lecture-based learning. This proved especially true for topics such as the different types of error (i.e. near miss versus no harm incident) that can be difficult to grasp for preclinical students. Next steps include improving the event based on targeted feedback and incorporation into the formal medical school curriculum.

A NEW APPROACH TO OUTPATIENT GERIATRICS TRAINING: AN INTERPROFESSIONAL POLYPHARMACY INTERVENTION USING THE SHARED MEDICAL APPOINTMENT MODEL John Thomas^{1,2}; Anne Hyson^{1,2},

Marcia C. Mecca^{1,2}; Kristina Niehoff²; Susan A. Zapatka²; Susan T. Langerman²; Leila Islam²; Rebecca Brienza^{1,2}. ¹Yale University School of Medicine, New Haven, CT; ²Veterans Affairs (VA) Connecticut Healthcare System, West Haven, CT. (Tracking ID #1934252)

NEEDS AND OBJECTIVES: Despite the growing number of elderly patients seen in primary care practices across the United States, dedicated outpatient geriatrics training for Internal Medicine (IM) residents and other health professionals remains limited. Our main objective was to pilot a team-based geriatrics intervention for patients with polypharmacy as an innovative approach to geriatrics education for IM residents and other health professional trainees. Our secondary objective was to evaluate the potential of this intervention to facilitate trainee education in outpatient geriatrics.

SETTING AND PARTICIPANTS: In an interprofessional outpatient team-training program at a VA hospital, we involved IM residents, nurse practitioner (NP) fellows, health psychology residents, and pharmacy residents (hereafter referred to as trainees) in the intervention.

DESCRIPTION: The intervention consisted of a shared medical appointment (SMA) and individual provider visit. The patients were ≥80 years old, with ≥10 medications, and were referred by their provider to participate. The SMA was co-facilitated by the trainees and consisted of interactive discussions about patients' experiences with medications. The individual visit, which was also conducted by the trainees, included standard geriatric assessments (St. Louis University Mental Status Exam, activities of daily living, and orthostatics), medication reconciliation, shared decision making regarding medication changes, and a detailed follow-up plan. Discussions were aided by the Beers criteria and a compilation of organizational disease-based guidelines. Afterward, we administered an anonymous online survey to the trainees to assess their experiences with the program.

EVALUATION: After the pilot, we administered an anonymous online survey to the trainees to assess their experiences with the program. Of the 4 IM residents, 2 NP fellows, and 1 pharmacy resident who participated in both the SMA and provider visit, all but 1 completed the survey (86 % response rate). All respondents agreed or strongly agreed that the program "has the potential to substantially improve my ability to safely decrease inappropriate prescribing for older patients." All respondents agreed or strongly agreed that the following aspects of the program, among others, were valuable for their education and development as clinicians: "geriatric assessments," "shared medical appointment," "working with an interprofessional team," and "shared decision making process." For this same question group, one respondent was neutral about "safe follow-up planning and execution." The free text comments were generally positive, but 4 respondents expressed the need for improved communication with the primary provider before and/or after the intervention.

DISCUSSION/REFLECTION/LESSONS LEARNED: We successfully piloted a team-based, outpatient geriatrics intervention for patients with polypharmacy. The participating trainees agreed that numerous aspects of the program were valuable for their education and development as clinicians. Future work will include enhancing communication with primary providers regarding clinical findings and medication changes, and introducing interprofessional trainee seminars focused on topics related to polypharmacy.

A NOVEL AMBULATORY CARE CURRICULUM: TEACHING THE SKILLS OF INFORMATION MANAGEMENT AND LIFE-LONG LEARNING
Margaret Horlick^{1,2}; Jennifer Rockfeld²; Mary Fishman²; Patrick M. Cocks²; Barbara Porter². ¹NY Harbor VA Healthcare Center, New York, NY; ²NYU School of Medicine, New York, NY. (Tracking ID #1940151)

NEEDS AND OBJECTIVES: How do we teach the skills required for lifelong learning? Curriculum objectives: 1. Residents will demonstrate the skills needed to maintain their medical knowledge over the course of their career. 2. Residents will demonstrate the ability to teach their peers and lead a small group discussion. 3. Residents will practice self-reflection in regards to their medical knowledge, patient care, and teaching skills.

SETTING AND PARTICIPANTS: This curriculum was given to PGY-2 s and PGY-3 s during their 2 ambulatory care blocks each year. There were a total of 84 residents who participated in the curriculum.

DESCRIPTION: In this era of multiple information sources and changing practices, it is essential that residents develop facility with the skills required to keep up with the literature, answer a patient-centered clinical question, critically appraise articles, teach their peers, and integrate feedback and new information into their own practice improvement. To address these essential skills and to evaluate residents in the

appropriate reporting milestones, we developed an ambulatory care curriculum in lifelong learning. Through several different exercises, residents learn to quickly and critically browse abstracts from the current literature, to ask patient centered clinical questions and find practical, evidence-based answers, identify their own knowledge gaps and to make short presentations to their peers on a current development in outpatient medicine. Each resident led conference includes the collection of written peer feedback, which the resident uses in guided self-reflection to develop an improvement plan for future presentations.

EVALUATION: Individual conferences are well received and we have observed improvement in the targeted skills as senior residents have taken the course for the second and third time. The quantitative evaluation of the conferences ranges from averages for each conference of 4.36 to 4.6 on a 5-point Likert scale. Qualitative comments include the following: "Good to learn how to critically appraise lit[erature]", "Good way to practice presentation" "Good for life-long learning skills" "Nice to see how attendings look up a clinical question" "Really good, liked using interesting clinic cases we've just seen" "Great to see different approaches to searching questions" "Very useful, made me enthusiastic about reading up on my patients." "Was a good exercise how to formulate and search for clinical questions."

DISCUSSION/REFLECTION/LESSONS LEARNED: Over the past year and a half we have learned that a key to teaching lifelong learning skills is for residents to use these skills as they learn topics that are relevant to their current clinical practice. As examples, honing teaching skills is coupled with delivering essential outpatient content and critical appraisal skills is coupled with reviewing recently published abstracts. Our curriculum fuels clinical curiosity as we develop as physicians and teachers. Over the course of the last 18 months, we have observed the residents providing more specific and constructive feedback to their peers suggesting that regular opportunities to give structured feedback improves the content and usefulness of that feedback. We have found that residents are more likely to incorporate the feedback from their peers in their self-evaluations than feedback given only by faculty.

A NOVEL APPROACH TO INTERPROFESSIONAL EDUCATION (IPE) FOR RESIDENTS ON AN INPATIENT MEDICAL SERVICE Matthew F. Griffith¹; Darcy Donaldson³; Eric A. Young^{2,1}; Robert Burke^{2,1}. ¹University of Colorado, Aurora, CO; ²Denver Veterans Affairs Hospital, Denver, CO; ³Denver Veterans Affairs Hospital, Denver, CO. (Tracking ID #1929844)

NEEDS AND OBJECTIVES: Poor interprofessional communication is the leading cause of medical errors. The quality of communication and collaboration between members of interprofessional teams is associated with patient morbidity. However, few residency programs integrate interprofessional communication training into their inpatient curriculum. Published examples of interprofessional education (IPE) training have focused on pre-clinical medical students, CRM training of operating room staff or resource-heavy TeamSTEPPS events that last multiple hours to multiple days. Few have targeted Internal Medicine residents. Additionally these models tend to focus on communication during the care of a patient in crisis, through high fidelity simulation, rather than the interprofessional communication skills needed to avoid these crises. Our objective was to design an intervention to improve interprofessional collaboration and communication at the primary training site of medical residents, the inpatient medicine ward, that achieved similar outcomes to existing models and required fewer resources.

SETTING AND PARTICIPANTS: The Denver VA is a 167 bed tertiary care facility. Inpatient housestaff belong to the University of Colorado Internal Medicine resident training program. The residents in the University of Colorado training program rotate through inpatient rotations at four hospitals in the Denver metro area in four-week blocks. The VA was chosen as the site for this teamwork training based on feedback from residents that indicated their communication with nursing was the least successful at this site compared to the others. Nurses in their first year of employment at the VA participate in an on-the-job training program with protected time to participate in quality improvement and patient safety activities. Nurses from this cohort participated in this training during protected education time that coincided with the regularly scheduled resident lunch conference at the Denver VA Hospital. Medical students attending the University of Colorado School of Medicine, as part of their Internal Medicine clerkship at the VA, also took part in the conference.

DESCRIPTION: Prior to the conference, a Chief Resident in Quality and Patient Safety and members of nursing education and leadership arranged a one-shift structured shadowing experience for a medicine resident and an RN. This experience allowed both practitioners to observe the daily workflow of the other profession and

report back observations regarding barriers to communication and teamwork elucidated by their new perspective. The conference consisted of an introductory discussion of common communication errors between professions, a problem-based learning activity requiring multidisciplinary teamwork, a discussion led by the providers who participated in the shadowing focusing on lessons learned during their experience, and a debriefing focused on specific behaviors both professions could adopt to improve collaboration between professions.

EVALUATION: A 5-question survey was distributed to participants before and after the conference, using a 10-point Likert scale (10 = highest) to rate agreement with prompts assessing changes in attitude, understanding of topics presented, and utility of the conference. Although 61 % of participants reported prior training in interprofessional communication, they reported significant increases in their comfort communicating with providers of other professions (before training 7.5, after training 8.0 $p<0.01$), their ability to identify common causes of communication error (6.9, 7.8 $p<0.03$), their ability to describe what a practitioner of the other profession does in the hospital (5.2, 7.2 $p<0.01$) and their ability to involve practitioners of other professions in efforts to improve communication (7.1, 8.1 $p<0.01$). Practitioners of both professions felt that this conference improved their understanding of interdisciplinary communication and 91 % of participants would highly recommend (score of 8 or higher) this training for their colleagues. We will evaluate resident assessment of nursing at the end of the year to see if this conference, when repeated with different cohorts of residents, improves assessments of VA nursing performance and communication.

DISCUSSION/REFLECTION/LESSONS LEARNED: Few residency programs integrate IPE into their resident curriculum and fewer still integrate it into the inpatient ward experience where excellent communication between providers is crucial. We have described a novel, one-hour multidisciplinary session requiring few resources that improved providers' self-identified ability to identify and address communication issues between professions and was highly regarded by participants. We anticipate that by repeating this conference regularly we will improve resident and nursing communication at our hospital, enhancing patient safety.

A NOVEL EVALUATION SYSTEM USING DIRECT OBSERVATION AND FORMATIVE FEEDBACK Jeremy Smith; David Feldstein; Christie Seibert; Bennett Vogelman. University of Wisconsin, Madison, WI. (*Tracking ID #1897528*)

NEEDS AND OBJECTIVES: Direct observation of trainees has been shown to increase frequency of feedback, identify clinical deficiencies otherwise unrecognized, increase learner confidence, and improve learners' clinical skills. At our institution, however, direct observation of clinical skills was not being performed regularly. We also recognized that within the ambulatory block rotation, the single end-of-rotation summative evaluation being used by each faculty evaluator was inadequate and potentially lacking in validity, because each resident might interact with multiple different faculty during the rotation. Therefore, we designed a novel evaluation system and implemented it into residents' ambulatory block rotation to address these needs. Our objectives were to: 1. Increase the amount of direct observation of residents. 2. Improve faculty's attitudes towards direct observation. 3. Increase residents' feedback and improve the quality of residents' evaluations by moving from a single summative evaluation to multiple formative evaluations throughout the rotation. 4. Begin to develop an institutional culture wherein direct observation is seen by faculty and learners to be an integral part of the training process.

SETTING AND PARTICIPANTS: Twenty-nine residents per year rotate through a university-based ambulatory block rotation. Residents spend 1–3 months seeing outpatients 5 days per week, primarily in a general internal medicine clinic. Fourteen different faculty supervise residents on this rotation.

DESCRIPTION: Each resident was required to obtain 9 observations over the course of the ambulatory block, comprised of 3 observations from each of 3 clinical domains: history-taking, physical exam, and counseling/decision-making. We developed single-page, literature-based evaluation tools for each clinical domain, which were given to residents at the start of the rotation. They were instructed to work with their faculty member to select appropriate patients for observation. Residents gave the relevant form to the faculty member prior to the encounter, and faculty completed the form while observing the resident. After the encounter, the faculty provided the resident with feedback, and the completed form. The forms were collected at the end of the rotation. These 9 formative evaluations took the place of a single summative end-of-rotation evaluation.

EVALUATION: A total of 256 patient encounters were directly observed over 12 months. Twenty-six of 29 residents (90 %) completed all 9 observations. End of rotation questionnaires were completed by all participating residents; faculty

evaluators were surveyed 6 months after program implementation. Residents found the new system valuable, with 85 % reporting they had permanently changed aspects of their history-taking, physical exam, or counseling based on the feedback received. Forty-two percent of residents reported having previously been directly observed a total of 3 times or less throughout his/her residency; 100 % of residents were directly observed at least 7 times over the course of the rotation. Faculty reported that the program increased their use of direct observation. Forty-two percent of the faculty reported conducting direct observation at least 6 times per year prior to the program, and 75 % reported conducting at least 6 observations in the 6 months since the program started ($p=0.01$ for change in number of observations). Faculty attitudes toward direct observation also improved. Sixty-seven percent of faculty felt this new system made it more likely or much more likely that they would conduct direct observation in the future. Faculty rated on a 1–5 scale how burdensome they thought the observations were going to be, and how burdensome they actually found them to be; there was a significant ($p=0.015$) improvement in faculty perceptions of the burden of direct observation. When asked to rate how useful they found the direct observations in terms of their ability to evaluate and provide feedback, on a 1–5 scale (5 = extremely useful), 92 % rated 4 or 5. 83 % of faculty preferred the new system to the prior evaluation system which used a single summative evaluation.

DISCUSSION/REFLECTION/LESSONS LEARNED: The new evaluation system was successful in increasing direct observation of residents, and improving faculty attitudes toward direct observation. Some residents and faculty suggested that the observations should be more learner-centered and flexible, allowing the number of observations in each clinical domain to be modified based on the learner's self-assessed needs. Some residents noted the significant effort required to collect the 9 observations, though we believe putting the onus on the residents to obtain the observations was key to accomplishing them. Future efforts will focus on measuring whether this system leads to increases in direct observation conducted by participating faculty in other venues, and modifying the system so that the observations are conducted based on learner self-identification of areas needing improvement.

A PATIENT-CENTERED MEDICAL HOME (PCMH) RESIDENT ROTATION: TEACHING INTERNAL MEDICINE RESIDENTS THE PRINCIPLES OF PCMH THROUGH COMMUNITY-BASED PRIMARY CARE Janina L. Morrison^{1,2}; Jonathan Swartz^{3,4}; Donald Raum^{1,2}; Rosemarie Conigliaro^{2,1}. ¹Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine, Bronx, NY; ³Montefiore Medical Center, Bronx, NY; ⁴Albert Einstein College of Medicine, Bronx, NY. (*Tracking ID #1938757*)

NEEDS AND OBJECTIVES: Montefiore Medical Center (MMC) encompasses 22 primary care clinics, including six teaching sites. Since 2008, MMC has invested in transforming each clinic into a Patient-Centered Medical Home (PCMH), starting with the non-teaching community sites followed by the teaching sites. Resident participation in PCMH initiatives, coupled with structured educational activities, can better prepare residents for independent clinical practice and ensure that practice improvements reflect their needs. Recognizing this, medical directors and medical educators at MMC collaborated to create a PCMH rotation for residents with the following goals: (1) to introduce residents to the principles of the PCMH and, (2) to provide residents with an ambulatory experience in a community PCMH practice.

SETTING AND PARTICIPANTS: All third-year categorical internal medicine residents complete the 4-week PCMH rotation. Each resident is supervised at a community site by a primary care provider. These community providers complete several faculty development sessions on academic precepting to prepare for this rotation. The residents also attend their continuity clinic weekly and participate in didactic sessions facilitated by a PCMH faculty mentor trained in quality improvement.

DESCRIPTION: During the rotation, residents see patients at the community site and observe patient-care sessions with PCMH team members including the chronic care nurse, pharmacist, and diabetes educator. Residents participate in PCMH planning meetings at the community sites and their continuity sites. Facilitated by the didactic sessions, residents complete panel management activities for their continuity patients recently discharged from the hospital. Residents also discuss their patient outcomes data, including patient satisfaction. Residents complete an online curriculum of PCMH lectures on Patient Access, Quality Improvement, The Patient Experience, Health Insurance and Payment Methods, and Behavior Change.

EVALUATION: Residents complete evaluations of the rotation and a retrospective pre-post survey to evaluate changes in knowledge, attitudes, and behaviors. Each

monthly cohort has two sessions in which we collect qualitative feedback. As of January 2014, 19 residents have completed the rotation. In the evaluations received thus far ($N=9$), 100 % of residents reported the rotation was more than adequate or outstanding in meetings its educational objectives. The retrospective pre-post-survey ($N=9$, data collection ongoing) has demonstrated improved ability to identify PCMH resources (33 % pre, 77 % post), use PCMH resources (33 % pre, 88 % post), and use patient data for quality improvement (55 % pre, 77 % post). Qualitative feedback has been strongly positive regarding the benefits of exposure to efficiency in primary care, identification of optimal continuity of care, and the potential for teamwork in increased physician satisfaction.

DISCUSSION/REFLECTION/LESSONS LEARNED: The unique combination of exposure to community medicine and participation in PCMH initiatives has provided a rich learning experience for our residents. Next steps include expansion of the curriculum to first year residents, extending resident participation in PCMH planning efforts, and analysis of resident utilization data before and after participation. Going forward, we expect to see our residents as quality improvement champions, both within our institution and in their future endeavors as physicians.

A PORTABLE FACULTY PEER OBSERVATION AND FEEDBACK PROGRAM TO BUILD AMBULATORY TEACHING SKILL CAPACITY Athina Vassilakis^{1,2}; Sheira Schlair^{1,2}. ¹Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #1939337)

NEEDS AND OBJECTIVES: With increasingly complex healthcare delivery systems and limited trainee ambulatory care hours, clinician educators have increasing demands that may challenge their teaching effectiveness. Peer mentoring can be an effective way to provide ongoing faculty development. It has been linked to greater work satisfaction and improved work relationships. This study aims to use a faculty-generated list of ambulatory teaching skills to guide a peer observation and feedback (POF) exercise for teaching improvement in the ambulatory setting. Our objectives are that following the intervention, participating faculty will be able to goal-set to improve teaching skills and identify teaching strengths and weaknesses in order to deliver effective feedback on teaching skills.

SETTING AND PARTICIPANTS: The intervention is taking place in an urban ambulatory academic general medicine clinic at Montefiore Medical Center in Bronx, NY, between January 2014 and June 2014. All faculty have been invited to participate with no exclusion criteria.

DESCRIPTION: Faculty participation is voluntary. During a routine clinic faculty meeting, faculty brainstormed the skills they believed to constitute effective ambulatory teaching. These skills were then used to generate a "peer observation and feedback instrument" (POF-I), which is being used to facilitate the POF exercise. Faculty complete a pre and post intervention survey about their expectations, knowledge, and attitudes regarding teaching skills and POF. Participants will arrange for POF on a monthly basis for 6 months, and will complete a POF-I for each encounter (one form for observing faculty, one form for observed faculty). They will observe and give feedback once monthly during their administrative time. They are also observed monthly and given immediate feedback during their regularly scheduled precepting sessions.

EVALUATION: Outcomes studied (via encounter-based POF-Is and surveys) will include faculty's self and peer assessed ability to (1) set goals to improve teaching skills, (2) identify strengths and weaknesses of teaching encounters, and (3) deliver effective feedback on teaching skills. Programmatic evaluation will be ongoing. Data collection will be complete by Spring 2014. Analysis will include calculation of mean number of goals set, teaching skills, and teaching domains (chosen for individual teaching improvement), and feedback skill evaluation scores. Paired t-tests will be used to examine associations between outcomes. Initial process evaluation data showed that during group brainstorming, faculty was engaged in the activity, and was spontaneously able to list skills in six of the seven "Stanford Faculty Development Center" educational categories. Thus far, eight faculty members have opted to participate in the POF process. Despite some initial reservations, their contribution to the development of the POF-I seems to have promoted their interest in the POF exercise.

DISCUSSION/REFLECTION/LESSONS LEARNED: The extensive list of teaching skills developed during brainstorming demonstrates the collective knowledge that can be cultivated through collaborative work and peer mentoring. The observation that faculty's initial resistance to peer evaluation lessened with engagement in the peer feedback process highlights existing

barriers to enacting sustainable peer feedback programs. It also suggests that learner buy-in is essential during assessment method development and ground rule setting for faculty to be willing to share vulnerability in peer assessment.

A STRUCTURED INITIATIVE THAT ENHANCES RESIDENT AND FACULTY RESEARCH PRODUCTIVITY IN A COMMUNITY HOSPITAL SETTING Marianne Smith; Anita Szerszen; Suzanne El-Sayegh; Ursula Viola; Kathleen Ahern; Morton Kleiner; Neville Mobarakai; Terenig Terjanian; Mario R. Castellanos. Staten Island University Hospital, Staten Island, NY. (Tracking ID #1929408)

NEEDS AND OBJECTIVES: As a community-based hospital, our resources to produce research for our faculty and residents are extremely limited in comparison to large academic medical centers with strong infrastructures. Research productivity is essential for community-based hospitals that support physician training programs. Research activity is needed to fulfill ACGME scholarly requirements for both residents and faculty. Increasing faculty clinical responsibilities limit dedicated time for research. Key components of a successful program include a director, clear goals, a curriculum in research, dedicated time, a presentation forum and faculty mentors. While some of these elements were already in place in our department, much of the research was fragmented and there was no central forum to review and critique individual resident research progress. We proposed that research proficiency could be established by developing a complementary research initiative that re-organized resources already in place and centralized the entire research process, focusing on engaging residents and faculty in original research. With limited funding, we developed an infrastructure to enhance scholarly activity. Our objectives of the program were to: 1. identify key personnel in the department to lead this initiative, 2. create a research curriculum to build a culture of scholarship for lifelong professional development, 3. develop and centralize a system to monitor research goals, activity and progress. We were able to significantly advance our department's research productivity with our multifaceted approach.

SETTING AND PARTICIPANTS: Staten Island University Hospital is a 700 bed community based hospital in an outer borough of New York City. Our Internal Medicine Residency Program has 107 residents, 90 being categorical. Every PGY3 is required to present a research project at the annual Resident Research Competition prior to graduation. For our initiative, at the beginning of the academic year all PGY 3 residents were assigned, and met with, research mentors, who are faculty of the Department of Medicine Research Committee. Our hypothesis was that with proper guidance, we could increase the number of original projects versus case reports for the competition. Since all projects are required to have a faculty principal investigator (PI), more of our faculty would be involved in projects. The Clinical Research Manager provided education and support. Members of the research committee reviewed progress.

DESCRIPTION: In the 2012–13 academic year, we focused attention to develop a new strategy for resident research education. This included bi-weekly departmental research committee meetings to review and develop policies, resolve critical issues and monitor productivity. All PGY3 residents met with their assigned research mentors. A mentoring assessment was performed to evaluate resident projects to ultimately be presented at the annual Resident Research Competition. Follow up meetings were mandatory. The mentors assisted residents to develop projects and linked them with faculty Principal Investigators. The Departmental Research Manager focused efforts on research education, assisting with protocols and developing a research intranet site.

EVALUATION: Formative evaluation to date suggests that the residents feel that the top three most helpful resources are: research mentor meetings, PI guidance and research education/lectures. Many residents also commented that they would like the mentor meetings to start in their PGY1 year. There is an ongoing systematic evaluation in progress. Original resident research increased from 28.75 % in 2012 to 50 % in 2013. ACGME survey results showed a 19 % increase in satisfaction with scholarly activity from 2012 to 2013.

DISCUSSION/REFLECTION/LESSONS LEARNED: Conducting research for clinical investigators is a challenge, yet essential for introducing innovative therapies and advancing patient care. The restructuring of our research program has accomplished increased support and guidance for the residents though the mentors, the Clinical Research Manager and varied educational resources. We have increased resident satisfaction, increased original research, and created a more user friendly method for resources and submission of protocols. There is also now a more centralized venue for discussion and feedback by the committee, as well as, organized tracking of individual progress. Assessment of faculty publication productivity is in progress and will be examined as part

of summative evaluation. At present, program evaluation indicates that outcomes are being met and the multifaceted processes in place are effective. These efforts should eventually support our faculty to obtain publications and pilot data. This initiative was carried out without significant increases in our research budget. We believe that our initiative is reproducible in other programs.

ACCELERATING AMBULATORY APLOMB: A NOVEL IMMERSION BLOCK CURRICULUM FOR INTRODUCING INTERNAL MEDICINE RIS TO CONTINUITY CLINIC Jared W. Klein^{1,2}; Ginger A. Evans^{1,3}; Anna Golob^{1,3}; Caroline Rhoads^{1,2}. ¹University of Washington, Seattle, WA; ²Harborview Medical Center, Seattle, WA; ³VA Puget Sound Health Care System, Seattle, WA. (*Tracking ID #1935733*)

NEEDS AND OBJECTIVES: Interns in our program historically reported a long interval between beginning continuity clinic and developing confidence and competence with basic clinic processes and disease management. We believe this was driven by their low-level, intermittent exposure to clinic. Therefore, we created an intern ambulatory immersion block with the following objectives: (1) improve intern comfort in continuity clinic by familiarizing them with clinic processes and support staff and (2) develop ambulatory skills including information management, communication, and disease-specific knowledge.

SETTING AND PARTICIPANTS: All interns in our large, multi-site, university-affiliated internal medicine residency program participate in a four-week ambulatory immersion block without inpatient responsibilities during one of the first 3 months of intern year.

DESCRIPTION: The immersion block is comprised of direct ambulatory patient care and a didactic curriculum. Interns spend three to five half-days per week seeing patients in continuity clinic, building a panel and learning to work with their interdisciplinary care team. The didactic curriculum, delivered during three to five half-day sessions per week, includes seminars on: (1) Disease management: core primary care conditions taught by an interdisciplinary team of physicians, pharmacists, dieticians and physical therapists; (2) Practice management: developing systems of care including charting, tracking patients and between-visit care; (3) Communication skills: agenda-setting, shared decision-making, medication counseling, and communicating test results; (4) Select physical exam skills: joint exams, cardiac exam, etc.; and (5) Evidence-based practice: formulating clinical questions, finding current evidence and effectively utilizing information resources.

EVALUATION: Interns who participated in immersion blocks during the 2013–2014 academic year ($n=54$) completed pre- and post-block surveys to assess the utility of the immersion curriculum. Substantially all of the interns reported exposure to primary care during medical school, with most reporting a four-week experience. In a free response question asking interns to describe their emotional state before clinic, trainees reported feeling excited but also anxious and overwhelmed. After completing the rotation, interns reported increased confidence in a wide spectrum of skills, as measured by the amount of attending supervision they felt was necessary (complete, partial, minimal or none). For example, at the beginning of the immersion block, 35.8 % of interns felt they needed complete supervision when diagnosing common musculoskeletal complaints, but only 5.6 % of interns felt they needed that same level of supervision at the conclusion of the rotation. Similarly, there was a 44.2 % increase in the number of interns reporting they could independently negotiate a mutually agreeable agenda for a clinic visit. All respondents felt the skills learned during the immersion block would be relevant to their future careers.

DISCUSSION/REFLECTION/LESSONS LEARNED: Adoption of a curriculum to familiarize internal medicine interns with continuity clinic at the beginning of their training increases early confidence with important primary care skills. Our data suggest this curriculum may set the stage for a more fulfilling experience with primary care throughout residency.

ADAPTING TO A MILLENNIAL LEARNING ENVIRONMENT: AN INTERNAL MEDICINE RESIDENCY CURRICULAR IMPROVEMENT PROJECT Suzanne Brandenburg¹; Cynthia Brandenburg²; Mel Anderson^{1,3}. ¹University of Colorado, Aurora, CO; ²Champlain College, Burlington, VT; ³Denver VA Medical Center, Denver, CO. (*Tracking ID #1939274*)

NEEDS AND OBJECTIVES: Because both the learning styles of today's residents and the practice of medicine itself are changing, the effectiveness of traditional lecture-based content delivery is rapidly diminishing. The current project reflects ongoing efforts to innovate and transform didactic sessions in response to the unique

needs and characteristics of "millennial" learners in order to better prepare them for the realities of medical practice in the digital age.

SETTING AND PARTICIPANTS: At the University of Colorado's Internal Medicine Residency Program, curricular transformation of weekly academic half day sessions, delivered by faculty for 2nd and 3rd year residents, will occur over a 3-year period.

DESCRIPTION: The 3-year strategy for curricular transformation includes: 1) Assess needs through faculty and resident surveys. 2) Reduce the amount of specific content covered in sessions; promote critical thinking through interactive activities and capitalize on available technology to enhance information literacy when accessing digital information. 3) Garner faculty interest and provide faculty support and professional development for transforming pedagogy. 4) Involve the learners (specifically residents in the "clinician-educator" pathway) in curriculum redesign. 5) Pilot transformed sessions. 6) Solicit resident feedback. 7) Modify transformed sessions as needed. 8) Implement fully transformed curriculum.

EVALUATION: The effectiveness of curricular change will be assessed using a variety of measures, including post-session feedback via immediate online surveys, average ABIM Certification exam scores, annual faculty and resident satisfaction surveys, and periodic surveys of program graduates.

DISCUSSION/REFLECTION/LESSONS LEARNED: Initial survey results indicate that while both residents and faculty see room for improvement in educational sessions and residents are generally less satisfied with the current curriculum than faculty. For example, when asked to respond on a 4-point Likert scale to the statement "the sessions are a valuable part of resident training" (1 = strongly disagree, 2 = disagree, 3 = agree, 4 = strongly agree), the average was 2.81 for residents compared to 3.23 for faculty. When asked to respond to "the sessions are important to help residents become confident independent practicing physicians," the resident average was 2.65 versus 3.03 for faculty. Resident feedback regarding piloted transformed sessions has been positive; preliminary post-session feedback from the first transformed cardiology session indicated 100 % of residents found the session's objectives to be both meaningful and successfully met. However, since we are only in the first year of our curriculum transformation, more time will be needed before any substantive conclusions can be drawn. Challenges include engaging the large group of faculty who traditionally lecture to residents based on their fields of expertise but have no specific protected time to either learn new teaching approaches or adapt their materials. Furthermore, we recognize the need for a nuanced evaluative tool to measure complex critical thinking and decision-making skills; we hope to develop a modified version of Script Concordance to serve this need. Additional strategies we are considering for the next phase of the project include improvement of independent and online learning materials, facilitated resident and faculty focus groups, and establishment of a Faculty Learning Community.

ADVENTURES IN PILOTING AN INTERPROFESSIONAL OBESITY CURRICULUM Tamasyn Nelson; Melanie Jay; Shonna Yin; Allison Squires; Charity Hung; Lisa Altshuler. New York University Medical Center, New York, NY. (*Tracking ID #1936644*)

NEEDS AND OBJECTIVES: Treating obesity is a complex task and barriers to effective counseling include lack of adequate time during clinical encounters and insufficient provider training. Further, providers become frustrated when they perceive that obese patients are not motivated to change their lifestyles. Implementation of obesity curricula within graduate health professions education programs to address these barriers is important. Use of a curriculum that incorporates an interprofessional approach may foster and facilitate collaborative efforts among health professionals; a multi-disciplinary approach to the treatment of obesity is considered to be especially effective. We sought to design an interprofessional curriculum in obesity counseling that could be individualized based on learner needs and would be appropriate for use across the lifespan and which focused on acquisition of skills related to two domains: 1) motivational interviewing (MI) and 2) health literacy.

SETTING AND PARTICIPANTS: The curriculum was piloted in the Department of Pediatrics in an urban academic hospital with three residents and two nurse practitioner students. It is scheduled to be piloted with Ob/GYN and internal medicine residents.

DESCRIPTION: The curriculum included 3 one-hour interactive sessions followed by an evaluative OSCE. Materials for the sessions were compiled by adapting existing curricula that had been developed separately for pediatrics and internal medicine residents. To this curriculum we included additional items based on a needs assessment obtained from the program director and trainees. The first session included discussion about perceived barriers to obesity treatment and a review of

health literacy principles and obesity counseling as well as a brief introduction to MI. The second session focused on challenges in the assessment of the literacy levels of patients and an introduction to specific MI skills, such as change talk and goal setting. The third session was reserved for role playing using the skills learned in the first two sessions. Each session concluded with plans for skills practice within the clinical setting.

EVALUATION: We evaluated the curriculum with a 10-minute OSCE station counseling a resistant adolescent on weight reduction. Participants were assessed on use of counseling techniques, including MI skills. Following the OSCE, qualitative feedback was obtained from the trainees via a written survey and audio-taped debriefing session.

DISCUSSION/REFLECTION/LESSONS LEARNED: Learners had strong feelings of frustration and resignation about their experiences with obesity counseling and were initially resistant to using MI. To address this, we strove to create an environment where learners could be honest about their perceptions and attitudes. Feedback from participants indicated that there was increasing acceptance of MI over the sessions. Learners highly valued the opportunity to learn in an interprofessional setting, identifying areas of similarity and difference in approach to obesity counseling.

ADVOCATING FOR ADVOCACY TRAINING IN MEDICAL SCHOOL: TOO LITTLE TOO LATE? Valerie G. Press; Cassandra D. Fritz; Monica Vela. University of Chicago, Chicago, IL. (*Tracking ID #1934127*)

NEEDS AND OBJECTIVES: The question of whether physician advocacy should be a mandatory component of medical school training is not new, though to date, data are limited on the impact of such mandatory curricula. The objectives were to: 1) explore students' understanding of advocacy in medicine; 2) provide a structure for students to explore advocacy and their commitment to advocacy; and 3) help first year medical students begin to define themselves as advocates within the profession of medicine.

SETTING AND PARTICIPANTS: This was a prospective qualitative study that followed 88 first year medical students in the Fall 2013 Health Care Disparities (HCD): Advocacy and Equity course as they learned about topics on health and health care disparities, heard from experts across multi-disciplinary fields about advocacy in medicine, and participated in experiential learning through group community projects and a field trip to our county hospital. Our IRB exempted this study.

DESCRIPTION: HCD is a first year course with mandatory attendance. We thought that this course provided an ideal opportunity for new medical students to learn about and explore advocacy in a formal and guided manner. Therefore, the 2013 HCD course was modified to include advocacy-specific learning: lecturers provided their view and experience with advocacy, written assignments focused on guided essays that encouraged self-reflection, and advocacy-specific lectures and large group discussions were introduced. To explore students' understanding of advocacy in medicine prior to matriculation, students were surveyed on their pre-course experience, knowledge and beliefs about advocacy related topics. To provide a structure for students to explore advocacy and their commitment to advocacy the students participated in lectures, small group projects, in-class discussions, and a field trip to Cook County Hospital. To help first year medical students begin to define themselves as advocates within the profession of medicine, students completed several mid-course self-reflective essays gauging their reactions to, and understanding of, the topics being presented. To explore students' understanding of advocacy in medicine after completing the course, the students completed a follow-up survey. Short essays were independently coded by three investigators; short-answer statements were answered on a five-point likert scale.

EVALUATION: The pre-course survey showed that the vast majority of students (93 %) had prior experience working with underserved populations, and 77 % spent greater than 15 h on this activity. About half (53 %) said that they or someone they knew had faced a health or health care disparity. After taking the course, students noted that their definition of advocacy broadened to incorporate multiple modalities. Prior to taking the course, 73 % of students agreed/strongly agreed, 24 % were neutral, and 3 % disagreed/strongly disagreed with the statement: "I consider myself an advocate;" after the course those in agreement increased to 86 %, those who were neutral decreased to 10 %, and those who disagreed remained at 3 % ($p=0.006$). There were not significant differences between pre/post-course sentiments about whether access to basic health care is a fundamental human right ($p=0.3$) or whether all medical students should become involved in community health efforts ($p=0.1$).

DISCUSSION/REFLECTION/LESSONS LEARNED: Our course provided an ideal format of guided learning in which to explore medical students' understanding

of, and commitment to, advocacy in medicine through experiential learning activities and self-reflective assignments. We found that several students began to define themselves as advocates specifically within the field of medicine. However, we did not find that their beliefs about access to health care or participating in community efforts changed after taking the course. Therefore, beliefs underlying the core elements of advocacy are likely formed prior to matriculation, while self-identification as "an advocate" may be more malleable. Our study has limitations. This course took place at a single institution without a comparator group. Therefore we cannot comment on whether our results are generalizable or would differ if the course activities were not mandatory. With the nation's growing attention and dedication to addressing and eliminating health and health care disparities, physicians will need to understand that our profession extends beyond the clinical encounter into the socio-cultural context. However, based on our results, beliefs on advocacy are likely formed prior to medical school matriculation, hence medical school curriculum, mandatory or otherwise, may be too little too late. Therefore, if an additional goal of medical schools is to promote a field of physicians dedicated to advocacy, admissions committees should recognize the limitations of post-matriculation education, and may consider evaluating for evidence of existing motivation for advocacy efforts during the application process through applicant responses in essays or interviews.

AN INTERACTIVE ONLINE MODULE TO ADDRESS LGBT HEALTH DISPARITIES Philipp Hannan¹; Rita Lee². ¹CU SOM, Aurora, CO; ²University of Colorado, Denver, CO. (*Tracking ID #1926376*)

NEEDS AND OBJECTIVES: Within the health care system, lesbian, gay, bisexual, and transgender (LGBT) persons face inequity that contributes to health disparities. A 2011 survey found 21 % of LGB individuals had been refused services by health care providers due to their sexual orientation, a rate that increased to 53 % among transgender respondents. Sixty-five percent of LGB and 85 % of transgender respondents felt there were insufficient adequately trained health care professionals to address their LGBT-specific needs. Only 61 % of respondents were "out" to their providers; of those that were not "out," 41 % feared their provider was not supportive of LGBT people. The key features that would make their provider LGBT-friendly were provider comfort with their sexual orientation or gender identity, LGBT-inclusive forms, and specific knowledge around LGBT health issues. A 2013 survey of Colorado physicians showed 82 % were "totally comfortable" with LGB patients and 51 % were "totally comfortable" with transgender patients if they self-disclosed their sexual orientation or gender identity. However, only 47 % reported being "totally comfortable" asking patients about sexual orientation or gender identity. Most indicated a desire to make their practice more LGBT-friendly. Thus, a conundrum exists. Most providers perceive themselves to be LGBT-friendly and are comfortable if LGBT patients self-disclose their sexual orientation or gender identity, but they don't ask. LGBT individuals want friendly providers, but don't tell due to fear of discrimination. We can begin to address these issues by improving provider comfort with asking about sexual orientation and gender identity, increasing their knowledge around LGBT health issues, and providing tools to create an LGBT-friendly practice. Therefore, we developed an online educational module with the following learning objectives: 1. To describe the health disparities LGBT individuals face 2. To describe the specific healthcare needs of LGBT individuals 3. To list the steps a practice or healthcare provider can take to create a welcoming and safe environment for LGBT individuals

SETTING AND PARTICIPANTS: A one-hour long, interactive, online module that is available to all health care providers with internet access.

DESCRIPTION: Using Adobe Captivate, we developed an online module that addresses LGBT demographics and each of the learning objectives listed above. Based on adult learning theory, the module includes: availability to interested learners at their convenience (timely); pre- and post-tests to document knowledge gains (goal-oriented), embedded videos showcasing LGBT experiences (relevant), links to online resources for additional learning (self-directed), and simple, explicit instructions on creating a more welcoming environment for their LGBT patients (practical). Much of the module is interactive to enhance learner engagement. The module is approved for 1 h of continuing medical education credit.

EVALUATION: This is a new module and no evaluation data is available at this time. There is an optional evaluation survey embedded in the module. The module is also being monitored via Google Analytics to track number and location of learners.

DISCUSSION/REFLECTION/LESSONS LEARNED: Our hope is that creating an hour-long, clinically-relevant, practical, interactive, online module will increase

provider engagement with the material. Ultimately, our goal is to increase the number of health care providers that have the knowledge, attitude, and skills to provide culturally responsive, clinically appropriate care for LGBT patients. Our dissemination strategy will require a multifaceted approach to reach a broad audience.

AN INTERDISCIPLINARY COLLABORATION SERVING AS THE BASIS FOR INTERDEPARTMENTAL GLOBAL HEALTH EDUCATION Minesh Shah¹; Huang Amy²; Clemence Sullivan¹; Lillian Francia¹; Andrew Dykens¹. ¹University of Illinois-Chicago, Chicago, IL; ²University of California San Diego, San Diego, CA. (*Tracking ID #1934748*)

NEEDS AND OBJECTIVES: As interest in global health grows, many residency programs have developed global health tracks or rotations for trainees. At the University of Illinois at Chicago (UIC), collaborative global health tracks have been developed for residents in the departments of family medicine, internal medicine, and internal medicine-pediatrics. The tracks focus on an interdisciplinary collaboration to establish community-based participatory research at the local level in a low-income country, through which residents learn first-hand how to conduct responsible, sustainable, and community-based projects. The international experiences are supported by an interdepartmental longitudinal 3-year curriculum that includes topics in community and public health, tropical medicine, health disparities, and the social determinants of health.

SETTING AND PARTICIPANTS: The global health tracks at UIC work through a partnership between a low-or-middle-income country (LMIC) community, Peace Corps, and an academic medical center. The partnership facilitates local level primary health care access with community-participatory primary health care services quality improvement as the aim. Our current project brings together the community of Guaymate, Dominican Republic; Peace Corps Dominican Republic; and UIC. Residents from the three aforementioned departments are engaged in ongoing planning and participate in faculty-led biannual site visits to advance partnership strengthening, assessment, development, implementation, evaluation, and dissemination through an iterative cycle.

DESCRIPTION: In the summer of 2012, we identified Guaymate, Dominican Republic as an ideal community partner. With a Peace Corps volunteer (PCV) as a liaison, we integrated into the healthcare community. Through focus group discussions and an onsite needs assessment, we identified several areas of need, and are currently coordinating the implementation of a broad health services quality improvement project in the Guaymate Municipal Hospital. The resident role is to assist with planning, facilitate local meetings, conducting data collection interviews, and assist faculty with bidirectional Continuing Medical Education seminars with local physicians. In Chicago, residents have monthly project meetings, during which they divide up tasks that include: contributing to writing and submission of the IRB protocol, curriculum development for the Guaymate QI project, logistics planning of site visits, and communication efforts with onsite partners.

EVALUATION: Evaluation tools have been created for the collaborative partnership and the global health tracks. Survey instruments assess partnership participation and satisfaction, and community-defined outcomes. Residents are also evaluated on knowledge, skills and attitudes related to global health topics.

DISCUSSION/REFLECTION/LESSONS LEARNED: The goal of this partnership approach is to offer responsible global health education through LMIC community engagement that fosters the sustainable strengthening of local health services. Our approach de-emphasizes global health education through intermittent clinical service provided by US personnel and cultivates skills of community engagement, health systems strengthening, and health services implementation research. The interdisciplinary effort allows residents to build relationships with non-medical professionals, while the interdepartmental aspect broadens residents' viewpoints. Each piece of this collaboration complements another. The model is designed for replication in other international communities and academic medical centers.

ONLINE RESOURCE URL (OPTIONAL): Department of Family Medicine Global Community Health Track: <https://sites.google.com/a/uic.edu/uic-dfm-global-community-health2/> Department of Med-Peds Global Community Health Track: http://chicago.medicine.uic.edu/departments__programs/programs/residencies/combined_medicine_pediatrics/_global_community_health_track/

AN INTERPROFESSIONAL CARE TRANSITIONS CURRICULUM FOR AMBULATORY INTERNAL MEDICINE RESIDENTS AND NURSE PRACTITIONER STUDENTS Melissa Bachhuber^{2,1}; Shalini Patel^{2,1}; Candace Kim³; Bridget O'Brien^{2,1}; Rebecca L. Shunk^{2,1}. ¹San Francisco VA Medical Center, San Francisco, CA; ²University of California San Francisco, San Francisco, CA; ³San Francisco VA Medical Center, San Francisco, CA. (*Tracking ID #1939309*)

NEEDS AND OBJECTIVES: Primary care providers play an essential role in care transitions of patients across the continuum of care, yet little formal training in care transitions occurs in the ambulatory care setting. We developed an interprofessional care transitions curriculum aimed to enhance trainees' understanding of care transitions from perspectives of patients, multidisciplinary providers, and systems of care. The specific program objectives included: 1) Define the role of the primary care team in preventing hospital readmissions and the importance of an interprofessional approach to patient care to reduce readmissions; 2) Identify barriers to effective care transitions and describe transitional care models and local programs, 3) Recognize characteristics of patients appropriate for transitional care programs.

SETTING AND PARTICIPANTS: At the San Francisco VA Primary Care Clinics, internal medicine resident trainees are paired with nurse practitioner (NP) students in practice teams and care for a shared panel of patients. Residents and NP students attend curricular sessions together in a collaborative learning environment.

DESCRIPTION: The interprofessional care transitions curriculum was delivered in eight sessions to internal medicine residents ($n=20$) and NP students ($n=14$) over 2 months per academic year. The curriculum overview session discussed national and local care transitions data, such as hospital readmissions and emphasized four transitional care models. Key components of care transitions including functional assessment, palliative care, hospice, social services, living environments, and care coordination were emphasized in case-based sessions with an interprofessional faculty expert. Trainees applied transitional care concepts in a session reviewing a preventable readmission case focused on congestive heart failure management. Trainees conducted a home visit on a patient from their own primary care panel. Nine faculty members from geriatrics, occupational therapy, physical therapy, social work, nursing, and pharmacy participated as content experts for components of the curriculum. The content of each session was developed through collaborative efforts of primary care faculty with an interprofessional faculty expert lead.

EVALUATION: A total of 34 trainees participated in the care transitions curriculum over two academic years. Trainees evaluated the curricular sessions on a 5 point Likert scale and provided written feedback. Overall, trainees rated the curricular sessions as a mean 4.6 in overall quality of the learning session and 4.4 in likelihood for changes in clinical practice as a result of the sessions. Qualitative comments from trainees highlighted aspects of the sessions they found most valuable, including: insight into key components of successful care transitions and enhanced understanding of the role of the primary care team in transitional care.

DISCUSSION/REFLECTION/LESSONS LEARNED: The implementation of an interprofessional care transitions curriculum is feasible in an ambulatory care setting. Our care transitions curriculum enhanced trainees' understanding of barriers to effective care transitions, transitional care programs, and increased awareness of the primary care team role in preventing hospital readmissions. Bringing together interprofessional faculty to emphasize key components of care transitions provided trainees with better understanding of interprofessional team member roles during care transitions and was important to the success of the curriculum. Primary care faculty worked closely with interprofessional faculty content experts, particularly if they were less experienced with a case-based approach to education and with teaching primary care trainees.

ASSESSING AND IMPROVING PATIENT CARE SKILLS THROUGH A BOOTCAMP FOR NEW RESIDENTS Luke Cunningham; Chirayu Shah; Nainesh Shah; Prathit Kulkarni; Kaushal Patel; Steffanie Campbell; Anoop Agrawal; Richard J. Hamill. Baylor College of Medicine, Houston, TX. (*Tracking ID #1937842*)

NEEDS AND OBJECTIVES: As new residents start their Internal Medicine training in July, many studies have raised concerns about patient safety associated with inexperienced residents, also termed the "July effect." Based on surveys conducted at our Internal Medicine residency program, there is considerable variation in the patient care experiences and skills of incoming interns starting residency training with only 53 % of incoming interns receiving a course for transition to intern year. Reviews of recent intern experiences revealed insecurities in communication, cross-cover, and procedural responsibilities. Studies evaluating this relationship

between clinical knowledge and experience have generally concluded that the decline in knowledge is accompanied by a decrease in quality of care.

SETTING AND PARTICIPANTS: During Internal Medicine resident orientation at Baylor College of Medicine in June 2013, 68 interns participated in a full day training bootcamp divided into three sessions: Procedural training, 8 Cross-cover case simulations, and Teaching Sessions. The teaching sessions were entitled Art of Handoffs, Art of Floating, Art of Patient Presentations, and Art of Efficient Note Writing. All sessions were completed within the medical classrooms and within simulated patient rooms.

DESCRIPTION: The procedural training included hands-on practice with basic ultrasound techniques, central line placement, and managing a code blue situation. Faculty led small groups of interns (4–6) through central line placement and mock code situations with each intern having the opportunity to place a line independently. Cross-cover simulations were done one-on-one with common overnight patient issues: chest pain, shortness of breath, altered mental status, hypotension/sepsis, atrial fibrillation with rapid ventricular rate, acute GI bleeding, acute stroke, and headache. Each session was limited to a duration of 15 min with 3 min reserved for individual feedback.

EVALUATION: All residents were sent a pre-intervention and post-intervention survey about their self-reported comfort level with communication skills, procedural skills, and cross-cover scenarios. There was significant improvement in comfort level for each cross cover scenario: chest pain 3.0 to 4.0, shortness of breath 2.8 to 4.0, altered mental status 2.6 to 3.6, hypotension/sepsis 2.7 to 3.6, atrial fibrillation 2.6 to 3.6, acute GI bleeding 2.4 to 3.7, acute stroke 2.3 to 3.7, and headache 3.1 to 3.8 [n= 67, response rate 98.5 %, Likert scale 1 = very uncomfortable, 5 = very comfortable]. Resident self-reported comfort level with the following procedures also increased: central line placement 1.6 to 2.9, code blue scenario 2.0 to 3.3, and using an ultrasound 2.8 to 3.6 [Likert scale 1 = very uncomfortable, 5 = very comfortable]. Seventy-seven percent strongly agreed and an additional 17 % agreed that Bootcamp should be continued for future orientation sessions.

DISCUSSION/REFLECTION/LESSONS LEARNED: The full day training workshop prior to starting residency significantly improves intern comfort with patient care management skills and likely patient care. The workshop also helps the residency program to implement milestone-based assessments and track further progression during intern year. Future directions include improving observed assessment of handoff skills and assessing impact on patient safety.

ASSESSING THE IMPACT OF A RESIDENT TOOL CREATED BY SENIOR MEDICAL STUDENTS PURSUING CAREERS IN INTERNAL MEDICINE

Ronald Omino; Elizabeth Grier; Katherine L. Fontichiaro; Diane L. Levine. Wayne State Univ SOM, Detroit, MI. (*Tracking ID #1939492*)

NEEDS AND OBJECTIVES: At the beginning of a clerkship, there is often a great deal of confusion regarding what is expected of both the residents and the students. Generally, the students will receive some sort of course syllabus with a list of goals and objectives for the clerkship that helps to provide some guidance. However, the expectations of the residents are not usually as clearly described. The LCME ED-24 describes, “Residents and other instructors who do not hold faculty ranks (e.g., graduate students and postdoctoral fellows) receive a copy of the course or clerkship/clerkship rotation objectives and clear guidance from the course or clerkship/clerkship rotation director about their roles in teaching and assessing medical students.” In order to address this expectation, we have created an “Orientation to My Team” document and a “Teaching Manual for Resident Physicians”. Our goal is to provide more structured guidance for internal medicine residents who teach medical students on the wards. Once the tools have been distributed residents will be given time to personalize their orientation document. We will then assess the impact of these tools on the quality of the team orientation and resident teaching quality and effectiveness during the Internal Medicine Clerkship.

SETTING AND PARTICIPANTS: Wayne State University Internal medicine residents at the Detroit Medical Center, a large academic healthcare system in Detroit, MI, as well as, third-year medical students at Wayne State University School of Medicine who are on the Internal Medicine Clerkship.

DESCRIPTION: A committee was created consisting of fourth-year medical students at Wayne State University School of Medicine who plan to pursue residency in internal medicine. This committee created a list of specific instructions for residents to use when initially orienting the new medical students to their ward teams. The committee also put together a list of tips on how to help the students learn as much as possible during the clerkship and how to get the most value out of their clinical experience. These

recommendations were based on the personal experiences of the fourth-year students during their clerkships, and included topics that they had found helpful or that they had wished were discussed with them during their internal medicine clerkships. In order to effectively implement the use of these tools, at the beginning of each new clerkship rotation residents will be given the lists and instructed to read and go over them with the medical students on their team. Signatures from both the medical students and the residents will be collected to make sure the form was discussed in its entirety.

EVALUATION: A survey at the end of the students’ internal medicine clerkship will be used to assess the impact that the resident orientation had on their ward experience. Students will score their team orientation and the contributions of the interns and residents to their education on the wards. These surveys will be compared to identical surveys that were completed by medical students before the creation and use of the resident orientation tool.

DISCUSSION/REFLECTION/LESSONS LEARNED: Results are currently pending. The goal is that with written guidance provided to the residents that outlines their expectations, they will better understand how to help their students get acclimated to the clinical setting and gain as much educational value as possible out of the Internal Medicine Clerkship. The specific tools used in this project will be available for use.

ONLINE RESOURCE URL (OPTIONAL): https://drive.google.com/file/d/0B9GC533GPAP_TJuREkzUjVTWVs/edit?usp=sharing

BLENDING RESEARCH AND RESIDENCY: THE CLINICAL SCIENTIST AND INTERNATIONAL SCHOLARS TRACKS Peter D. Bulova; Kathleen M. McGigue. UPMC, Pittsburgh, PA. (*Tracking ID #1934592*)

NEEDS AND OBJECTIVES: To recruit an elite and diverse group of medical graduates who have a clear ambition to pursue careers in academic medicine, both from US and international medical schools To train future clinician-investigators to serve as key contacts and bridges for international collaboration in medical clinical research and medical education. To develop future leaders in research and academic medicine To develop programs to help residents gain research skills and experience in the context of internal medicine residency training.

SETTING AND PARTICIPANTS: Over the past decade, we have recruited US and International medical graduates for two research-tailored tracks (Clinical Scientist Track and International Scholars Track) within our categorical residency program. Selection is based on evidence of excellence in clinical care and interest in a career involving research. At the end of the 3-year residency, graduates are eligible to sit for the American Board of Internal Medicine (ABIM) Certification Examination. Clinical training in the research-tailored tracks is similar to that of the categorical training program and conforms to requirements of the Residency Review Committee and the ABIM. Time is protected for didactic research training and mentored research experiences designed to produce first-authored manuscripts.

DESCRIPTION: Residents participate fully in our traditional 3 year residency. They devote 2 elective months to formal clinical research training using an established curriculum, and one or more research projects. Residents have assigned clinical and general research mentors. In addition, each resident chooses a research mentor (or mentoring team) for their mentored research project, specific to his/her field of study. Mentored research occurs throughout the residency. All participate in a monthly seminar series to discuss research issues and gain research presentation skills.

EVALUATION: These residents have performed extremely well in our residency. All have successfully completed the residency, were eligible to sit for, and passed the boards. The number of publications of our program participants far exceeds that of our categorical residents, while they have still performed well clinically. For example, in 2011–2012 the international scholar residents averaged 2 publications in peer reviewed journals per resident (32 by 16 residents), compared with an average of 0.5 per categorical resident. The mentored research component of these tracks has served as model for integrating research more broadly into our clinical program. Among 14 graduates who responded to post education surveys, all took positions in a school of medicine; 54 % as fellows, 23 % as residents, and 23 % as clinical educators. Program graduates (n=14) assessed the program on a 7-point Likert scale, quite strongly agreeing that they were satisfied with the overall quality of the coursework [mean 6.0 (SD 1)], that the program expanded their research skills [5.9 (SD 1.0)], increased their interest in multi-disciplinary research [5.2 (SD 1.5)], and contributed positively to their overall training [5.92 (SD 1.0)].

DISCUSSION/REFLECTION/LESSONS LEARNED: The programs have added diversity and an avenue for research to the program without compromising the clinical mission. Residents have found the integration within the general categorical program to be its most important component. Recruitment of talented scholars from around the world to a specific curriculum has created a successful model of academic training for international

medical graduates seeking research careers in subspecialties of internal medicine. The International Scholars and Clinician Scientists have served as models for integrating research and scholarly projects into our categorical clinical program.

ONLINE RESOURCE URL (OPTIONAL): http://www.residency.dom.pitt.edu/Program_Overview/tracks/isp.html http://www.residency.dom.pitt.edu/Program_Overview/tracks/cstp.html

BUILDING THE DIVERSITY BRIDGE ABROAD: THE STRATEGY TO IMPLEMENT PRE-GRADUATE CULTURAL COMPETENCY MEDICAL EDUCATION IN LAUSANNE, SWITZERLAND Alejandra Casillas^{1,2}; Sophie Paroz³; Elody Dory¹; Francis Vu¹; Patrick Bodenmann¹. ¹Lausanne University Hospital, Lausanne, Switzerland; ²Hopitaux Universitaires de Genève, Genève, Switzerland; ³Lausanne University Hospital, Lausanne, Switzerland. (*Tracking ID #1934518*)

NEEDS AND OBJECTIVES: Although the United States has been central in bringing cultural competency (CC) into the discussion of high-quality care, health systems all over the world are faced with the effects of global immigration and the widening disparities gap between socioeconomic classes. Lausanne University Hospital is one of five Swiss academic medical centers chosen to develop programs addressing CC. Here we focus on our CC medical student training as a model for other international settings looking to build CC curricula based on best practices, but tailored to their local context.

SETTING AND PARTICIPANTS: At Lausanne University Hospital, diversity is part of clinical practice. Just over a third of the patient population is non-Swiss, and include undocumented and recently arrived refugees. The center serves other high-risk and vulnerable populations. The strategies presented here focus on medical students at the Lausanne center. Given the midpoint of medical studies and the beginning of clinical activity, we specifically concentrate on student evaluations ($n=80$) of the three CC training modules at the 3rd year level (of six) for 2012–2013.

DESCRIPTION: Tailored to our European context, this curriculum is influenced by programs developed by experts at the Massachusetts General Hospital and Harvard Medical School. A CC-focused session is delivered to students at various points each year. Primary topics are social determinants of health, cultural groups in the local community, stereotypes, and unintended biases. Early sessions begin with medical anthropology material which raise consciousness of the learner's own potential biases. By the 3rd year, education evolves to a more case-based medical training- focusing on the social determinants of health through clinical vignettes linked to disparities (mental health, HIV). The three sessions are: Health and Migration, Communication/Trialogue (working with an interpreter), and LGBT health disparities. In the 4th and 5th years, students may enroll in a 12-week health disparities elective and community immersion experience, respectively. In the 6th year, these students rotate in the ambulatory clinic for a month and develop a health disparities project (thus exposing them to our primary care residency for potential recruitment).

EVALUATION: We present an evaluation of a portion of this curriculum for the 3rd year students. In November 2013, students submitted evaluations for the three CC half-day seminars specific to their year ($n=80$); classes incorporated the presence of a patient, group interviewing guided by the instructor, videos of simulated case encounters, and case discussions. Sessions were conducted in groups of 20–30 students with an overall mean satisfaction score of 4.1/5 (highest-5). “General interest” and “acquired knowledge” were highest for the Health and Migration session (4.5 and 4.1, respectively).

DISCUSSION/REFLECTION/LESSONS LEARNED: We describe one of the few medical student CC curricula in Europe. We present the theoretical framework and pedagogical models that have been most applicable to our endeavor since its inception in 2005, educational content, developmental approach, and assessment by 3rd year medical students in clinical rotations. In summary, we provide a “roadmap” for international health-education systems developing CC student training, in the context of their local setting.

CARING FOR REFUGEES AND ASYLUM SEEKERS: PRIMARY CARE AND FORENSIC DOCUMENTATION IN REFUGEE HEALTH AS PART OF AN INTERNAL MEDICINE RESIDENCY CURRICULUM Jessica Hurst; Matthew T. Corey. Boston University, Boston, MA. (*Tracking ID #1936655*)

NEEDS AND OBJECTIVES: 1. Increase resident knowledge about refugee medical needs and legal, social, and educational resources in greater Boston. 2. Provide

residents with hands-on experience in forensic medical examinations for asylum-seekers. 3. Provide continuity of primary care for refugee patients.

SETTING AND PARTICIPANTS: Setting: A clinic dedicated to the primary care and forensic medicine needs of Boston refugees. Preceptors are attending physicians from the division of general internal medicine at Boston Medical Center, New England's largest safety-net hospital. Participants: Interested categorical and primary care internal medicine residents.

DESCRIPTION: The innovation has two components. 1. Forensic Medical Evaluation Elective: This elective has been available to primary care residents for approximately 12 years. It consists of one afternoon per week of supervised visits with patients who are applying for asylum. Residents assist in reviewing cases and conducting a forensic medical exam to document evidence of prior ill-treatment based on the Istanbul Protocol. 2. Refugee Primary Care: This was started as a pilot with one resident in January 2013 and expanded to any interested residents in July 2013. As part of their ambulatory week, residents may choose a second continuity clinic in refugee primary care, supervised by faculty with expertise in refugee health and forensic evaluation.

EVALUATION: 1. Forensic Medical Evaluation Elective: Between one and three primary care residents have participated annually. Several program graduates have gone on to conduct forensic medical exams in their primary care practices. 2. Refugee Primary Care: Five residents have chosen to participate. Throughout 2013, there have been a total of 36 visits with 28 unique patients from 9 different countries. 3. Plans to measure quality and results: Monitor patient health metrics and outcomes, design tools to evaluate resident experience and pre- and post-rotation knowledge in refugee health.

DISCUSSION/REFLECTION/LESSONS LEARNED: Current strengths: 1. Training residents in the discipline of global health at their home institution. 2. Disseminating current best-practices in refugee health; participating residents share their knowledge of refugee health screening and available resources with others in the residency program. 3. Supporting Boston Medical Center's longstanding mission to provide care for the underserved. 4. Utilizing BMC's rich supply of phone and in-person interpreter services, covering 203 languages. 5. Expanding residents' landscape of potential careers in general internal medicine. Areas for improvement: 1. Developing a formal, written curriculum, both for participating residents and as a published model for other institutions. 2. Expanding the program to include residents from other specialties, in order to provide unified, multidisciplinary care for refugees with complex care needs. Sustainability and dissemination to other institutions: 1. Maintaining the existing program at Boston University will require recruiting new faculty members and encouraging upper-level trainees to take on teaching roles. 2. Financially, the primary care program is self-supported based on billing Mass Health (Massachusetts' Medicaid program) for services. This may be problematic in states with less robust health insurance options for refugees. Forensic medical evaluation is not covered by any insurance plan and must be supported through highly competitive grant funding. 3. Adoption of a refugee clinic model at other institutions depends on dedication of clinic space, ancillary staff, faculty time, and resident ambulatory elective time.

CARING FOR THE HOMELESS AND UNDERSERVED: AN ONLINE, SYSTEMS-BASED, INTERPROFESSIONAL CURRICULUM Davoren Chick^{1,3}; April Bigelow²; F. Jacob Seagull³; Heather Rye⁵; Pamela Davis^{1,4}; Brent C. Williams¹. ¹University of Michigan, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI; ³University of Michigan, Ann Arbor, MI; ⁴University of Michigan, Ann Arbor, MI; ⁵University of Michigan Health System, Ann Arbor, MI. (*Tracking ID #1938597*)

NEEDS AND OBJECTIVES: Many medical residents lack formal training regarding social determinants of health, public healthcare systems, or special interprofessional care needs of the medically underserved. Internal medicine curricular milestones include an expectation that residents reflect awareness of socioeconomic barriers impacting patient care, but a national curriculum has not been formalized. Locally, University of Michigan internal medicine residents scored an average of 44 % on a baseline needs assessment quiz in these content areas. Residents who rotated through underserved clinical venues with a traditional informal curriculum showed no significant improvement in knowledge. To address identified needs, we developed a sharable online curriculum regarding public healthcare systems and bio-psychosocial care for the underserved. We stressed interdisciplinary education and innovative adult learning methods by forming an interprofessional curriculum design team and incorporating a novel, game-based learning tool.

SETTING AND PARTICIPANTS: With support from a Graduate Medical Education Innovation grant from the University of Michigan Medical School, we formed a curriculum design team comprising the fields of nursing, social work, internal medicine, pediatrics, medical education, communications, and graphic design. The final curriculum was posted to a freely accessible website. Current participants include over 250 registered learners from numerous medical and nursing institutions across the United States.

DESCRIPTION: Through iterative refinement, the curriculum design team identified two relevant curricular domains supporting care of at-risk populations. Each of the two domains was divided into knowledge content modules: *Domain 1. Public Healthcare Systems* includes modules on epidemiology of the homeless and medically uninsured, public health insurance systems, and public healthcare delivery systems; *Domain 2. Bio-Psychosocial Model of Care* includes modules on biomedical needs of the homeless, social determinants of health, the bio-psychosocial model of health, and interprofessional team care. We produced case-based learning modules for each of these content areas and packaged the curriculum in a professionally designed web site: "Caring with Compassion". The website includes an individualized learner dashboard, case-based didactic modules, extension resources, a trifold case formulation pocket guide, and a milestone-based assessment tool. The core knowledge curriculum is supplemented with a case-based online game that integrates core content into an enjoyable, low-risk learning experience.

EVALUATION: Nationally, hundreds of residents have enrolled in this curriculum. Additionally, the curriculum is in use by nurse practitioner and medical students, and is now a core resource for University of Michigan Medical School and School of Nursing courses regarding care of underserved populations. Faculty across multiple institutions report assigning the website for independent learner review and using the resources during small group discussions. Qualitative feedback has been highly positive, with residency program directors stating that the curriculum addresses significant gaps in the traditional graduate medical curriculum. Preliminary quantitative outcome data demonstrates highly significant improvement in multiple choice examination scores following exposure to the modules and game for all assessed content areas [n, pre-test, post-test, T test p value]: epidemiology of populations in need (42, 49 %, 81 %, $p<0.0001$); health care delivery systems knowledge (19, 53 %, 67 %, $p<0.002$); homelessness and disease (20, 59 %, 82 %, $p<0.0001$); public health insurance (30, 52 %, 80 %, $p<0.0001$); team care (14, 45 %, 64 %, $p<0.001$); social determinants (29, 51 %, 56 %, $p=0.022$).

DISCUSSION/REFLECTION/LESSONS LEARNED: This freely shared online curriculum addresses identified national and local gaps in socioeconomic and sociobehavioral knowledge for medical learners. Curricular components can be used individually or as a comprehensive curriculum. Medical educators and learners have expressed appreciation both for the cohesiveness of the compiled curriculum and for the flexibility of implementation options provided by the online modular format. Further plans include expansion of faculty development tools, expansion of the learning game through addition of a second game case scenario, and continual revisions based on curricular feedback. Challenges moving forward include securing time and resources to update content, maintain the website, and measure and monitor learner outcomes. High quality, freely accessible, interprofessional online curricula are highly appreciated resources for academic medical and nursing institutions. Shared online curricula are an important and valued direction for the future of a national medical curriculum and for academic recognition of medical education scholarship.

ONLINE RESOURCE URL (OPTIONAL): <http://caringwithcompassion.org>

CHAPLAINS ON THE MEDICAL TEAM: AN INTERPROFESSIONAL PARTNERSHIP IN PATIENT CARE Patrick Hemming; Paula Teague; Ty Crowe; Rachel Levine. Johns Hopkins University, Baltimore, MD. (*Tracking ID #1931022*)

NEEDS AND OBJECTIVES: Many patients identify spirituality as important to their coping and medical decision making, but physicians generally have little training in spiritual assessment. Increased collaboration between physicians and hospital chaplains may encourage greater attention to patients' values. With this goal, we developed a shared educational experience for internal medicine ward teams and chaplain trainees in clinical pastoral education (CPE). The overall objectives are to: 1. Increase medical residents' confidence in talking to patients about spiritual needs 2. Increase medical residents' awareness of chaplains' roles 3. Increase collaboration between residents and chaplains in patient care

SETTING AND PARTICIPANTS: Beginning in 2011, we paired CPE trainees with one of the Internal Medicine resident inpatient teams at JHBMC. These CPE trainees are Masters-level theology students pursuing a clinical inpatient experience prior to

becoming chaplains. Each CPE trainee spends 1 or 2 days per week over a 3–4 week rotation with the medical team: attending, senior resident, two interns, two medical students. From 2011 until September 2013, eight CPE trainees had participated.

DESCRIPTION: The curriculum includes three phases: orienting, rounding, and partnering. Orienting: medical interns have an hour-long introduction to a spiritual assessment tool and chaplains' roles. CPE trainees' orientation includes an introduction to the medical team structure, and guidance about contributing appropriately to rounds. Rounding: the CPE trainee accompanies the team at bedside for at least 3 days over the rotation, and contributes to the discussion and plan. Partnering: CPE trainees and medical residents collaborate informally outside of rounds to care for patients identified as having need of a chaplain.

EVALUATION: Between October 2011 and May 2013, a pilot was conducted to evaluate the feasibility and appropriateness of the curriculum. We conducted focus groups with participating attending physicians (one group of 10), CPE trainees (one group of 3, one group of 4) and medical residents (one group of 4). Transcripts of the focus groups were recorded and analyzed by two researchers to develop a coding template that was applied to the transcript to develop themes. Regarding the educational experience, several themes emerged: 1. Physicians reported greater confidence addressing patients' spirituality from observing CPE trainees' communication techniques (listening, observing, and using appropriate language). 2. Physicians saw CPE trainees as liaison between the team and patient, and valued the emotional support CPE trainees provided to the team. 3. Keys to a successful collaboration include: (a) introduce team members by role (b) set clear expectations for team members (c) provide opportunities for feedback. The observations from theme 3 prompted specific changes in our curriculum. In a separate survey of medical residents (response rate 34/57=57 %), 83 % (vs. 17 % neutral) agreed that the rotation with CPE interns was beneficial to their learning by comparison with other rotations.

DISCUSSION/REFLECTION/LESSONS LEARNED: Involving physicians and chaplains in an interprofessional curriculum is an innovative approach to medical education and offers an effective strategy to simultaneously improve teaching in both professions and enhance patient care.

CLOSING THE FEEDBACK LOOP -EVALUATING AN INNOVATIVE SYSTEM TO PROVIDE FEEDBACK TO FACULTY ABOUT THEIR STUDENT ASSESSMENTS Neil Mehta¹; Alan L. Hull²; Amy S. Nowacki³. ¹Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH; ²Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH; ³Cleveland Clinic, Cleveland, OH. (*Tracking ID #1933607*)

NEEDS AND OBJECTIVES: Students need ongoing formative feedback that identifies specific strengths and areas for improvement, to compare this feedback to established goals and expectations, and to develop plans to improve targeted areas to become self-regulated learners. We have developed a web-based Clinical Assessment System (CAS) that allows all preceptors to provide timely formative feedback based on observed clinical encounters. While finding the time to provide formative feedback is a challenge, a bigger challenge is that clinical preceptors are more familiar with providing summative end-of-rotation feedback and may be unaware of the type of feedback that is most useful to help students identify learning needs, seek new knowledge or skills, and improve performance and understanding. To address this issue, we enhanced CAS to allow students to assess the usefulness of the formative feedback they receive from the clinical preceptors. The objectives of this project are to determine if these assessments can: 1. Reliably and validly identify preceptors for faculty development or for recognition; 2. Be aggregated to identify disciplines or clinical training sites for faculty development.

SETTING AND PARTICIPANTS: The study included 48 students from 1 of 3 tracks of a medical school during their core clinical rotations based at 3 medical centers. The track uses a competency-based portfolio system for assessment. This system requires students to write a reflective essay on 9 different competencies citing their formative assessments as evidence of meeting standards in each competency.

DESCRIPTION: The students log all their educationally significant patient encounters in CAS using any internet enabled device. The preceptors provide competency-based narrative formative feedback (both strengths and areas for improvement) for each of these encounters. When viewing this formative feedback online, students can rate the usefulness of the feedback using a 5-point Likert item of agree-disagree to the statement "This form identifies specific behaviors/skills that I did well and/or I can improve upon". The student rating is presently not shared with preceptors.

EVALUATION: Students rated the usefulness of 1,181 (59 %) forms out of 2,001 formative assessments completed by faculty between July–December, 2013 as follows: 56 % Strongly Agree (SA); 33 % Agree (A); 7 % Neutral (N); 2 % Disagree

(D); and 1 % Strongly Disagree (SD). Forty-two forms were rated D or SD. Twenty-four of these 42 forms had non-specific comments (e.g. "good history") rather than specific feedback about observed interactions while 11 had no competency specific comments. Only 4 of these forms were blank. Twenty-four of these forms were from 3 students. Other observations of these 42 forms included faculty copying and pasting the identified criteria into the feedback boxes and faculty who entered a number (e.g. 9/10) instead of comments in the feedback box. Each form rating was dichotomized as Useful (SA/A) versus Not Useful (N/D/SD). When restricted only to disciplines with at least 50 assessed forms, the usefulness of the forms differed according to discipline (73 % surgery, 83 % aging, 88 % pediatrics, 89 % OB/GYN, 91 % internal medicine, 91 % family medicine; Chi-square test $p=0.001$). The usefulness of the forms also differed according to clinical site (82 % vs. 87 % vs. 90 %; Chi-square test $p=0.05$). Faculty level statistics were computed for the disciplines with the largest number (internal medicine, $n=134$) and the most diversely rated (surgery, $n=32$) faculty. The majority of these faculty (81 %) had 3 or fewer forms rated by students. Points were assigned to each student's assessment of the usefulness of each form they rated: SD=0, D=2, N=5, A=8, SA=10; the average for each faculty being the feedback score. The median feedback score was 9.3, Q1=8 and Q3=10. Nineteen faculty (11 %) had average scores below 6 and were identified as providing student-reported non-useful feedback.

DISCUSSION/REFLECTION/LESSONS LEARNED: Formative assessments are critical to help students develop into self-regulated learners by letting them close the gap between goals and performance. Providing useful feedback to students is a faculty skill that can be improved. We describe a system for students to assess the usefulness of feedback they receive. Our analysis suggests that these data can be used to identify faculty who could benefit from faculty development on providing feedback and recognize faculty who consistently provide useful feedback. The next step is to validate the results with a different cohort of students doing their clinical rotations at the same sites, in the same disciplines with the same group of faculty. We also plan to compare student and expert assessments of usefulness from a randomly selected group of assessments and study the utility of using student assessments of usefulness as an outcome marker for faculty development. If borne out by these studies, this model can be replicated on other assessment systems and help both students and faculty in academic programs.

COLLABORATING WITH COMMUNITY ORGANIZATIONS AND NON-MEDICAL PERSONNEL TO IMPROVE RESIDENTS' MEDICAL SPANISH SKILLS INCLUDING COGNITIVE RETENTION AT 6 MONTHS Frances Norlock; Laura Sadowski; Jennifer Feld. Stroger Hospital of Cook County, Chicago, IL. (Tracking ID #1934926)

NEEDS AND OBJECTIVES: Cultural and language barriers have been documented as risk factors for disease, mortality, morbidity, access to health care and receipt of health care services. Spanish is the native language among 25 % of patients cared for by trainees at our institution and educators felt it was important to familiarize residents with this specific language. The objective of this medical education innovation was to improve healthcare providers' medical Spanish skills so that they could better communicate with Latino patients. Unique to the educational innovation compared to previous language curriculums was the assessment of language retention 6 months after completion of the rotation.

SETTING AND PARTICIPANTS: Fifteen internal medicine residents and 1 genetic counselor completed a dedicated medical Spanish rotation at an urban, public hospital. Language skills were taught through daily didactic language instruction; role-playing with professional patients; homestays with Latino families to practice conversational skills; shadowing physician visits in clinics serving the Latino population to improve listening skills; as well as completing an intensive computer-based Spanish language CD and a computer-based medical Spanish CD.

DESCRIPTION: Over the past 3 years 16 trainees spent 4 weeks in an intensive Spanish language course taught by an experienced Spanish language instructor. Didactic sessions were held each morning for 3 h before residents went to a variety of experiences to reinforce the language skills learned in the morning sessions. Role-playing sessions were moderated by the language instructor and were held between trainees and professional patients to improve listening and speaking skills. Each trainee participated in 5 home stays with Latino families in their homes to practice Spanish conversational skills. Trainees shadowed physicians twice during ambulatory patient visits in clinics serving the Latino population to improve listening skills. Lastly, trainees completed the computer-based Spanish language CDs in one assigned afternoon. Language acquisition (writing, listening, and reading) and cognitive retention of medical Spanish were measured at the beginning and end of the 4 week rotation and 6 months after completion of the program.

EVALUATION: After 4 weeks educators found a 48 %, 26 % and 57 % mean change improvement prior to the start of the rotation in written, listening, and reading skills,

respectively. Among trainees there were sustained improvements 6 months later with a mean change in improvement prior to the start of the rotation of 39 %, 12 % and 50 % in written, listening, and reading skills, respectively.

DISCUSSION/REFLECTION/LESSONS LEARNED: Residents were able to make improvements in medical Spanish writing, listening and reading skills with a 28-day language instruction course both at the end of the rotation and 6 months after completion of the rotation. This is the first time educators have shown a sustainable improvement over a 6 month follow-up period. The number of role-playing sessions with professional patients was increased based on feedback from the initial group of trainees. In the future, a speaking assessment will be included using a professional patient and evaluator as the Program Director felt this was an important component to evaluating future rotations.

COMMON DOLLARS, COMMON SENSE: HARMONIZING A HIGH VALUE CARE CURRICULUM ACROSS AMBULATORY AND INPATIENT SETTINGS IN AN ACADEMIC MEDICAL SYSTEM Reshma Gupta; Jacob Berman; Andrew Dervan; Anshu Abhat; Leah Marcotte. University of Seattle, Washington, Seattle, WA. (Tracking ID #1933710)

NEEDS AND OBJECTIVES: The Institute of Medicine estimates that as much as one-third of healthcare spending is waste. Although physicians play a central role in allocating healthcare resources, a recent cross-sectional study of physicians in JAMA showed that only 36 % of physicians see themselves as having a major responsibility to help reduce healthcare costs. In this context, training the rising generation of clinicians to deploy healthcare resources wisely has become essential. How do we empower residents to make high value, cost-conscious decisions at the point of care in an increasingly complex healthcare system? Objectives: - Enhance provider understanding of payment systems to illuminate the financial impact of clinical decisions on patients and the healthcare system - Shift paradigms from an inpatient vs outpatient dichotomy to a comprehensive view of cost and quality that spans time, disease and care settings - Motivate trainees to recognize the importance of physicians in providing resource-conscious healthcare

SETTING AND PARTICIPANTS: Across ambulatory and inpatient settings in a large, three hospital academic system including the University of Washington, Harborview, and Veterans Medical Center in Seattle for all internal medicine residents.

DESCRIPTION: We developed a curriculum focused on health systems and high value, cost-conscious care. Our curriculum includes 15 large group lectures providing a framework and vocabulary for health systems, ten small group workshops on delivering cost-conscious care, including six drawn from the Alliance for Academic Internal Medicine High-Value Care curriculum, and multiple initiatives throughout our program to make cost data more accessible to providers at the point of care. The large lectures cover topics including health systems structure, payment and financing, quality improvement, new health delivery models, and advocacy. The small group workshops are delivered through 30 min clinic conferences and 45 min inpatient morning reports in a coordinated effort across our three hospitals. We use hospital-specific data when possible and challenge participants to consider the most appropriate care setting for a given patient and problem.

EVALUATION: We conducted qualitative interviews of 15 medicine residents, probing their experiences in delivering coordinated, efficient care across ambulatory and inpatient settings. The themes extracted from these data include trainees' limited health systems fluency and observed difficulties in coordinating care to avoid system redundancies and frequent ED visits. Motivated partly by these data, we implemented this curriculum within the first three rotational blocks of our academic year. We will use survey data and semi-structured qualitative interviews to evaluate the impact of this curriculum on resident cost-consciousness, health systems knowledge, and ordering habits.

DISCUSSION/REFLECTION/LESSONS LEARNED: Implementing a broad-based health systems/high-value care curriculum across a large academic medical system is feasible. Key to this effort has been giving residents the background (through larger lectures) and tools (through workshops) to use actual local cost and outcome data to provide high value care. It was essential to identify key champions across ambulatory and inpatient settings to achieve this. Structuring the curriculum to span various didactic venues has enriched the learning experience and improved educational continuity by comprehensively exposing trainees to multiple models and cultures of care delivery.

COMMUNITY HEALTH IMMERSION CURRICULUM FOR PRIMARY CARE RESIDENTS Robin E. Canada. ¹University of Pennsylvania, Philadelphia, PA; ²Department of Public Health, Philadelphia, PA. (Tracking ID #1927792)

NEEDS AND OBJECTIVES: The University of Pennsylvania Primary Care Residency Program attracts residents who desire to care for the underserved, and our hospitals and clinics serve economically disadvantaged populations from West and Southwest Philadelphia. However there was little curriculum time or clinical experiences specifically addressing the needs of either patients or trainees. Thus, we developed our Community Health Immersion Curriculum, which was initiated in September 2013. The objectives were to: 1. Train physicians to understand the social determinants of health in order to better care for patients and prevent burnout. 2. Provide experience working in community sites to: a. Improve the practice of medicine with vulnerable populations through understanding the patient's life context, the resources available, and barriers to care b. Improve discharge practices for vulnerable populations c. Provide experience for career planning

SETTING AND PARTICIPANTS: This Community Health Immersion is mandatory for the Primary Care residents in their junior year; ($n=6-8$ annually) Residents rotate at one of the safety-net health clinics in West Philadelphia (Health Center #4), an HIV primary care site (The Jonathan Lax Center), and a student-run free clinic (United Community Clinic) during 1 month.

DESCRIPTION: Residents participate in a longitudinal didactic series on the social determinants of health throughout their Junior and Senior years. Presenters are researchers and practitioners working in academics, public health, and the community. Topics include: Community Health Centers, Social Determinants of Health, Gun Violence and Structural Causes of Disease, Racial Disparities in Cancer Screening, Research in Health Disparities, Homelessness, Immigrant Health, Mental Health Disparities and services in Philadelphia, Health Literacy, Tobacco Cessation and Obesity efforts. Additionally, trainees spend a month in the community practicing, tour community non-profits that address social determinants of health, and attend meetings on transitions of care. We plan to partner with a community-based organization to offer health topics and screening.

EVALUATION: Residents write a reflection of the month, meet with the course coordinator, and complete a standardized online evaluation. We aim to perform interviews of the residents completing the curriculum, and compare those to controls.

DISCUSSION/REFLECTION/LESSONS LEARNED: Two residents have rotated through our community health month. Their feedback was overwhelming positive. Resident 1: "Understanding where your patients are coming from is an important way to prevent burnout in trainees and one of the best ways to do this is show examples of community medicine at work so that the triumphs and challenges of patients can empower the trainee to care for patients competently and compassionately." "I am such a better inpatient doctor, understanding how my patients access care after discharge." Resident 2: "Ms. H's social situation - her lack of insurance, lack of support, and lack of disposable income - were not taken into account when she was discharged." "The rotation has made me rethink my career in academic oncology." Notably, a senior resident, who did not get the experience, commented that she "wished we had done this earlier—it might have changed my career." From this intervention we have learned that our residents are hungry for the opportunity to learn more about their patients through education and practice in community settings. We hope that this intervention will create doctors that better understand and serve their community.

CONTINUITY CLINIC IMMERSION FOR INTERNAL MEDICINE INTERNS: IMPROVING EFFICACY IN AMBULATORY CARE EARLY IN RESIDENCY TRAINING Soraya Azari¹; Emily E. Hurstak^{1,2}; Katherine Julian¹; Maya H. Dulay^{2,1}; Shalini Patel^{2,1}. ¹UCSF, San Francisco, CA; ²San Francisco VA Medical Center, San Francisco, CA. (Tracking ID #1933684)

NEEDS AND OBJECTIVES: Internal medicine residents spend approximately two-thirds of their training in the inpatient setting. With new duty hour changes and requirements, many training programs find it increasingly difficult to teach internal medicine interns how to provide effective primary care. Barriers include limited time spent in continuity clinic, patient complexity, and complex systems of care in resident continuity clinic settings. Our objective in designing this curriculum is to improve intern ambulatory medical knowledge, clinic systems of care knowledge and skills, and to enhance satisfaction with the continuity clinic experience.

SETTING AND PARTICIPANTS: All internal medicine interns at UCSF residency program were scheduled to take part in a one-month intensive ambulatory curriculum from June 2013 through January 2014 during the first 6 months of internship. Interns participated in the curriculum grouped by their clinic site: a university-based clinic, a Veteran Administration-based clinic and a county hospital-based clinic. Core clinic faculty, allied healthcare providers, and the ambulatory chief resident delivered the curriculum.

DESCRIPTION: Core ambulatory faculty from each clinic site met and agreed upon the immersion curriculum topics to be covered. This month-long intern immersion curriculum involved: 1. Increased continuity clinic sessions; 2. Ambulatory core didactics to increase medical knowledge on common primary care complaints and diseases; 3. Targeted curriculum aimed at enhancing effective team-based care through shadowing interdisciplinary team members and receiving interactive didactics from allied healthcare providers (ex: physical therapy, mental health providers, and social work); 4. Interactive didactics focused on navigating clinic systems including charting effectively in an electronic medical record, telephone and electronic communication with patients, and panel management; 5. Reflective sessions to allow interns to discuss challenges and accomplishments encountered in developing their ambulatory care skills; and 6. Dedicated time and opportunities to develop relationships with outpatient mentors.

EVALUATION: We delivered this educational innovation customized for each of our continuity clinical sites to 58 interns over 6 months. All internal medicine interns were surveyed every month from July 2013 through February 2014 regarding their perceived efficacy in their continuity clinic using an anonymous (coded by clinic site) paper-based survey tool. Comparisons will be made between responses from interns who have completed immersion curriculum to those who had not yet received the immersion curriculum in order to assess program effectiveness in improving medical knowledge, efficacy, and competence in continuity clinic settings. Independent evaluations of immersion didactic speakers were also obtained at all three clinic sites in order to guide future sessions and curriculum development. Qualitative data were also collected at the three sites. Examples of resident comments included: "The best part was having closely spaced clinic sessions which allowed me to get to know the clinic system" and "I also benefitted from shadowing a senior resident and learning their work flow." "I found it helpful to discuss the approach to a patient with chronic pain.... and appreciated learning about evaluating a u-tox result". Preliminary survey data reveal improved self-reported clinical efficacy, familiarity with staff and systems, and medical knowledge in continuity clinic settings. Interns valued shadowing opportunities, which fostered getting to know clinic staff, faculty, and resident mentors on a personal and professional level. The highest rated didactics were practical, concise, case-based sessions. Negative feedback included not receiving curriculum early enough in the academic year and too many sequential didactic sessions in a day. Responses were similar for primary care track and categorical interns.

DISCUSSION/REFLECTION/LESSONS LEARNED: Essential aspects of this program include scheduling immersion months as early in the academic year as possible, identifying clear learning objectives and checklists for shadowing activities, and involving ancillary team members and associated health professionals with formal and informal teaching responsibilities. Having a large number of learners immersed in clinic simultaneously can be a burden on staff and clinic resources, but developing best practice guidelines will aid core faculty to design and deliver effective immersion curriculum in the future. The success of this educational innovation has prompted discussion on the design and implementation of an advanced clinic immersion month for 2nd year residents to cover higher-level topics. Addressing the primary care workforce shortage requires creative curricular development to engage residents and improve clinic satisfaction so that they may envision rewarding careers as primary care providers.

ONLINE RESOURCE URL (OPTIONAL): NA

COOK HEALTHY EAT FRESH (CHEF): A PILOT STUDY OF AN INTERDISCIPLINARY SEMINAR TO AUGMENT MEDICAL STUDENT TRAINING IN NUTRITION AND CULINARY SKILLS Rob Caldwell^{1,2}; David M. Levine¹; Scott Vasher³; Jared Beller³; Lisa Sasson⁴; Melissa Lumish³. ¹New York University School of Medicine, New York, NY; ²New York City Health & Hospitals Corporation, New York, NY; ³New York University School of Medicine, New York, NY; ⁴New York University, New York, NY. (Tracking ID #1895433)

NEEDS AND OBJECTIVES: Health care providers are regularly expected to educate their patients in nutrition and weight management, yet formal medical student training is deficient in these areas. In response, our interdisciplinary team enhanced, implemented, and assessed a medical student seminar on healthy eating and cooking to focus on nutrition knowledge, food selection and preparation, and health promotion. This pilot also sought to assess the course's impact on participants' eating behaviors and perspectives surrounding nutrition and cooking as well as inspire them to share their practices with their patients.

SETTING AND PARTICIPANTS: 25 volunteer medical students at New York University (NYU) School of Medicine (SOM) participated in CHEF: Cook Healthy Eat Fresh. CHEF is an interdisciplinary para-curricular seminar led by faculty and student/resident volunteers from NYU's SOM and Department of Nutrition, Food Studies, and Public Health.

DESCRIPTION: With new objectives-based teaching strategies, CHEF created a hands-on environment where medical students learned basic culinary techniques while gaining an understanding of nutrition fundamentals and patient counseling. Students engaged in four 3-hour cooking sessions in a teaching kitchen and four 50-minute didactic sessions in a classroom. Cooking session themes included the Mediterranean and DASH diets, which were linked to classroom topics including the sociocultural aspects of nutrition, barriers to dietary change, and making informed food decisions.

EVALUATION: Eleven students enrolled and completed evaluations, examined through intention to treat analysis where possible. Nutrition promotion was assessed through the validated Nutrition in Patient Care Survey. Students significantly improved on 3 out of 5 scales ($p<0.05$). Participants' dietary practices were measured pre/post through the validated Automated Self-Administered 24 h Diet Recall (ASA24). Participants' intake of total calories decreased by 99.9 kcal ($p=0.45$). When the ASA24 scores were converted to the Healthy Eating Index (HEI) 2010, mean population scores increased from 70.66 to 73.89. Due to the complex HEI calculation, this portion of the analysis was performed among survey completers only. Food selection and preparation were evaluated through both a pre/post self-efficacy questionnaire and kitchen skills observation rubric. Self-efficacy improved in skill areas including roasting, simmering, sautéing, and stir frying ($p<0.05$). Students' perception of their ability to prepare meals adhering to the DASH and Mediterranean diets, as well as time-efficient and budget-appropriate meals also improved ($p<0.05$). Post-course, students on average felt they could incorporate healthy cooking and eating in their lives "with little difficulty," a significant improvement. Pre/post observation rubrics of kitchen skills did not demonstrate significant changes. Nutrition knowledge was assessed with exit surveys after each didactic session, which demonstrated >80 % mean mastery of content objectives.

DISCUSSION/REFLECTION/LESSONS LEARNED: CHEF demonstrated a trend toward improvement in participant behaviors and perspectives. We look forward to enrolling more students in subsequent semesters to fully evaluate the effects of CHEF. Here we describe an innovative seminar for the training of future physicians such that they eat and cook more healthfully and are more comfortable discussing healthful dietary behaviors, cooking skills, and weight management with their patients.

CREATING A REPORT CARD TO MEASURE AND REPORT INTERNAL MEDICINE RESIDENT COMPETENCIES IN THE USE OF THE ELECTRONIC HEALTH RECORD Scott Joy^{1,2}; Brian Dwinnell^{1,2}. ¹The Colorado Health Foundation, Denver, CO; ²University of Colorado, Denver, CO. (Tracking ID #1935156)

NEEDS AND OBJECTIVES: Effective and efficient use of electronic health records (EHR) is a skill that internal medicine residents need to develop early in their careers. There is no agreed upon standard upon which to evaluate a resident's skill regarding proper documentation within the EHR. We sought to develop a scorecard of relevant EHR documentation skills to provide feedback to residents on their performance regarding documentation of key data within the EHR.

SETTING AND PARTICIPANTS: 18 primary care track internal medicine residents (6 interns, 6 junior residents, 6 senior residents) at the University of Colorado who have their continuity clinic at High Street Primary Care Center at Presbyterian/St. Luke's Medical Center in Denver, Colorado.

DESCRIPTION: A checklist was developed that evaluated 11 key factors relevant to effective documentation in a general internal medicine practice, which included: 1. Meaningful Use (4 criteria, updated problem list, medication reconciliation performed, allergies verified, documentation of smoking cessation counseling provided). 2. Evaluation and Management Coding (5 criteria, documentation of new/established patient, complexity of diagnosis, amount of data reviewed, E/M and teaching code entered in billing section) 3. PCMH Requirements (2 criteria, goals for clinically important conditions documented, follow-up plan documented (f/u with whom, why and when)). These criteria were reviewed with each resident, and a summary sheet of the criteria were posted in obvious areas in the resident work area. At the end of a 6 month evaluation period, faculty retrospectively reviewed 3 resident notes from the evaluation period, including at least one progress note that was relevant to one of the practice's PCMH Clinically Important Conditions (diabetes, coronary artery disease, or depression). If the resident adequately documented the key factor in the note or if that factor was not applicable in that particular encounter, the resident received a point. If the key factor was not documented, the resident received 0 points. The sum of the points the resident obtained in each key factor was determined, and the percentage of resident key factor points/total key factor points was calculated.

EVALUATION: The range of resident scores regarding competencies in documenting within the EHR was 69 % to 100 %. The average score for the entire group was 84 %. The average score for the group of Interns was 92 %, range 80 % to 100 %, 67 % scored above average. The average score for the group of junior residents was 83 %, range 76 % to 93 %, 33 % scored above average. The average score for the group of senior residents was 77 %, range 69 to 90 %, 33 % scored above average.

DISCUSSION/REFLECTION/LESSONS LEARNED: A report card that evaluates resident competencies at meeting critical documentation goals in an EHR can be developed. Interns who had no previous interaction with old methods of documentation within the practice had the highest percentages of compliance with EHR task completion. Ongoing training and feedback regarding appropriate documentation skills using EHR for residents is paramount to optimizing the potential of the EHR.

CULTURAL COMPETENCE EDUCATION IN A SIMULATED CLINICAL ENVIRONMENT : A PILOT EXPERIENCE Sophie Paroz¹; Raphaël Bonvin²; Alejandra Casillas³; Sara Vadot²; Francine Viret²; Amaury Daele⁴; Patrick Bodenmann³. ¹Lausanne University Hospital, Lausanne, Switzerland; ²University of Lausanne, Lausanne, Switzerland; ³University of Lausanne, Lausanne, Switzerland; ⁴University of Lausanne, Lausanne, Switzerland. (Tracking ID #1926053)

NEEDS AND OBJECTIVES: Patients accumulate socio-cultural factors that interact with their care. In addition, contemporary European health services are confronted with a growing diversity according to language, country of origin, education, and/or religious beliefs. At the Department of Ambulatory Care and Community Medicine in Lausanne University Hospital, Switzerland, half of the patients are immigrant. The first attempts to manage diversity emerged 15 years ago, and included the development of a cultural competence (CC) curriculum for frontline medical doctors. In 2010, a survey showed that their self-perceptions of CC skillfulness was low and that their CC needed strengthening. New education strategies have therefore been implemented. Our main objective was to improve the clinical impact of CC education efforts. The secondary objective was to increase the perceived relevance of CC care, among providers.

SETTING AND PARTICIPANTS: The Department of Ambulatory Care and Community Medicine is an academic center comprised of 100 physicians. During residency training, a mandatory 4 h CC education module is in place, based on traditional and moderately interactive teaching media (clinical encounter videos, powerpoint, case vignettes). The first session focuses on addressing language and literacy issues, the second session on social context, and the third on beliefs and stereotypes. The fourth and final session emphasizes learned/prior principles through clinical cases. Prior to these efforts, only oral or written patient cases had been used. The target populations are general medicine residents and chief residents. The trainer is an attending physician.

DESCRIPTION: A pilot experience was supported by an education-innovation grant from Lausanne University and took place in September 2013. It focused on the 90 min fourth session of the module and was developed in accordance with a patient-based approach in a simulated interactive and supervised clinical environment. Two clinical scenarios were created based on an « upstream evaluation » of learners' needs. The first case involves a young Moroccan student with an undiagnosed gonococcal throat infection. Prejudice, sexual risk behaviour and sexual orientation were addressed in this vignette. The second case is about a 40 year old Albanian woman presenting with somatoform disorders. Treatment adherence, social integration and gender were touched upon in this segment. The following specific skills were integrated in the scenarios : to determine the socio-cultural factors affecting medical care; to identify a patient's understanding of his/her illness; to show the learner how to « teach-back »; to negotiate a treatment plan. Two simulated patients were trained for the role plays. A duration of 45 min was allotted to each case, this included group debriefing and a post-debriefing role play. Development of the session was supervised by a collaborative, interdisciplinary team of medical doctors, CC care specialists and educationists. Eleven physicians participated, five of them volunteered for the role play, and the rest were active observers.

EVALUATION: The experience was initially evaluated by an ad hoc form distributed directly after the session. Nine out of ten learners ($n=10$, 1 missing) rated their satisfaction as « very satisfied ». Eight out of ten considered that simulated patients helped them improve their CC and that the class increased their comprehension of CC. One month later, a focus group reunited six of the learners to complete these results. Clinical cases and simulated patients were considered « realistic » and the increased opportunities for interaction in the class were highly appreciated. The application of CC through a simulated environment was considered advantages in increasing self-reflection and improving individual provider practice. Specific and

planned improvements include 1) more time dedicated to the group debriefing, and 2) adding a discussion about the potential consequences of the generalisation of population groups related to CC learning cases.

DISCUSSION/REFLECTION/LESSONS LEARNED: The use of simulated patients has long been used in medical education. However, to our knowledge, this project is one of the few uses of simulated patients in a CC curriculum. Getting past a traditional CC curriculum and offering an educational setting that insists on interactivity, self reflection and real clinical practice is a relevant way to match the triad at the heart of CC « knowledge, attitude and skills ». As globalisation makes CC essential for medical practice, other settings are encouraged to take advantage of this international example : using innovative teaching medium adapted to the local contextual issues about diversity.

DESIGNING AND PILOTING A CURRICULUM IN CLINICAL EMPATHY FOR INTERNAL MEDICINE RESIDENTS, IN ORDER TO IMPROVE CLINICAL SKILLS IN CROSS-CULTURAL PATIENT CARE Nathan Bertelsen^{1,2}; Michelle DallaPiazza¹; Louis H. Miller¹; Antoinette Schoenthaler^{2,1}. ¹NYU School of Medicine, New York, NY; ²NYU School of Medicine, New York, NY. (*Tracking ID #1937125*)

NEEDS AND OBJECTIVES: Competency in cross-cultural sensitivity, awareness and communication is considered an essential skill for physicians. Clinical empathy is increasingly recognized as a skill linked to improved patient satisfaction, adherence, continuity, and trust in health care providers and systems. Accreditation Council for Graduate Medical Education (ACGME) internal medicine milestones include the expectation that all graduating residents demonstrate competency in cross-cultural care. The current project hypothesized that clinical empathy is a measure that can demonstrate this competency. To that end, a pilot curriculum was developed, in order to define, teach and assess clinical empathy for residents in internal medicine.

SETTING AND PARTICIPANTS: NYU School of Medicine offers a large ACGME residency training program in internal medicine in a diverse setting of New York City. Faculty with expertise in working with multicultural patient populations in various ways, as well as GME program leadership, were identified to develop content for this curriculum. These patient populations included immigrants who experienced psychological and physical trauma, persons living with HIV, and community groups dedicated to reducing health disparities. Over 90 current second- and third-year internal medicine residents participated in groups of 10–15 residents, over 7 monthly ambulatory care clinical rotations at Bellevue Hospital, a municipal hospital and teaching site for NYU.

DESCRIPTION: After reviewing clinical empathy literature and drawing on similar exercises used in other venues, teaching exercises were piloted in a one-hour session to each successive group of residents. Background on clinical empathy theory, self-awareness exercises, and videos were used. Clinical cases to illustrate empathetic challenges were discussed, which included adherence, informed consent, health literacy and numeracy, trust and continuity, language and interpreters, traditional health beliefs, and the concept of the healing environment.

EVALUATION: Throughout each session, residents were encouraged to explore their own cultural identities, engage actively in discussion of clinical empathy, and to share personal experiences of clinical empathetic challenges with their peers. Participating faculty used the new ACGME milestone #18, measuring whether each resident “responds to each patient’s unique cultural needs,” as a general guide for discussion. Resident feedback was reviewed after each exercise and adapted to each successive session, with the ultimate goal of a modular curriculum that can be adapted to multiple venues.

DISCUSSION/REFLECTION/LESSONS LEARNED: Clinical empathy offers a promising clinical measure in which to demonstrate effective cross-cultural patient care. Initial feedback from the residents indicated that they had difficulty understanding the relevance of clinical empathy to patient care through theoretical discussions on culture and empathy. However, the combination of self-awareness exercises and case-based examples which illustrated clinical empathy translating into better outcomes was more successful. One hour in a classroom was a major challenge to engage residents, while having more time and incorporating standardized patients would have likely improved outcomes. A major limitation was the need for an objective structured clinical examination in which to demonstrate improved skills in clinical empathy among residents. To this end, a focus group of faculty in general internal medicine at NYU has been identified to review and standardize these findings into a modular curriculum, which can be shared among multiple instructors within the ACGME milestone context, in order to define, teach and assess clinical empathy for training residents in cross-cultural patient care.

DEVELOPING AN ENTRUSTABLE PROFESSIONAL ACTIVITY (EPA) FOR RESIDENT-LED SHARED MEDICAL APPOINTMENTS (SMAS) Yamini Saravanan; Rebecca Toutant; Richard Pels; Patrick T. Lee. Cambridge Health Alliance, Cambridge, MA. (*Tracking ID #1939296*)

NEEDS AND OBJECTIVES: As academic, primary care clinics transform into Patient-centered Medical Homes (PCMH), how can Internal Medicine residency programs develop Entrustable Professional Activities (EPAs) to help faculty understand and evaluate newer PCMH skills? Entrustable Professional Activities (EPAs) capture clinical practice in an integrated manner, reflecting the multiple medical competencies that are involved in any one clinical activity (1,2,3). “Entrustment” specifies the competencies required for the resident to practice with progressive independence (1). As clinical practices transform to PCMHs, teaching faculty in these practices are unfamiliar with the principles of PCMH transformation and feel unprepared to teach trainees (2). We present our initial experience collaborating with residents to develop an EPA for a resident-led Shared Medical Appointment (SMA), an important strategy in PCMH deployment (3). The objectives are to: 1. Demonstrate a process by which our site collaborated with third year residents to identify an EPA for a resident-led SMA for diabetic patients. 2. Identify a set of preliminary clinical behaviors that characterize the EPA for resident-led SMAs.

SETTING AND PARTICIPANTS: The Primary Care Center (PCC) is a teaching, adult medicine clinic for nine internal medicine residents at the Cambridge Health Alliance, a safety-net community health system affiliated with Harvard School of Medicine. The PCC started resident led SMAs for diabetic patients in September of 2013. Every 6 weeks, third-year Internal Medicine residents co-lead an SMA.

DESCRIPTION: We conducted a series of three focus groups on residents to identify learning needs and to invite resident co-leadership in the SMA initiative. A series of skill building seminars, entitled “learning dinners,” were developed and hosted every 2–3 months. These learning dinners were co-led by a physician and a dietitian, with experience in group facilitation. An iterative reflection and narrative process facilitated ongoing learning and improvement. One week before each SMA, the third year resident and dietitian met to identify themes for discussion and to plan methods of facilitation. This plan was recorded in an e-group site, Evernote®, allowing colleagues and preceptors to provide constructive feedback. After each SMA, the resident posted “learning narratives” on Evernote. These included both Likert scale and open ended items to facilitate personal reflection. The physician and dietitian faculty provided additional feedback via e-mail after reading the learning narrative and observing the group. The feedback centered around specific behaviors to effectively manage the huddle or group that the resident did or did not demonstrate.

EVALUATION: We will qualitatively analyze the learning narratives, and feedback messages to identify common behaviors that made the group successful. These behaviors will in turn inform writing an EPA for a resident-led SMA. We will share the developed EPA with residents and SMA experts for further validation. We will present summarizes description of this EPA, mapped to specific behavioral expectations for the resident, and relevant competencies and PCMH principles.

DISCUSSION/REFLECTION/LESSONS LEARNED: This educational innovation outlines a process that can be used by other educational programs to develop EPAs for PCMH activities or for other novel clinical competencies in which faculty may have little or no experience. Further study needs to be done on whether these EPAs or the EPA paradigm more generally prove valuable for faculty and residents. Developing an EPA for any activity in which medical faculty are unprepared to teach and supervise will help (1) identify learning needs for residents and faculty (2) develop cross-disciplinary mentorship for residents, and (3) provide more concrete criteria for faculty to evaluate residents. The process presented is reproducible and relevant to other clinical programs.

DEVELOPING AND IMPLEMENTING AN INTERN TEACHING CURRICULUM Anna K. Donovan; David Linz; Carla Spagnoli. University of Pittsburgh School of Medicine, Pittsburgh, PA. (*Tracking ID #1934963*)

NEEDS AND OBJECTIVES: Teaching skills are critical for physicians, as evidenced by their inclusion in the Practice-Based Learning and Improvement ACGME Competency. These skills are honed slowly over many years, and can be thought of as taking place on a developmental continuum. Residency is the first venue where most physicians have an opportunity to formally teach. Yet, few published interventions describe teaching interns how to teach. A survey of our Internal Medicine interns and medical students in 2012 revealed that interns value teaching and significantly impact medical students’ learning on the wards; yet, the interns felt largely unprepared to teach. Given the findings of this needs assessment survey (Linz

and Spagnoletti, JGIM Supplement of SGIM Annual Meeting Abstracts, July 2013), we developed a curriculum to prepare interns for medical student teaching on the wards. Our clinician-educator faculty met several times to determine the teaching skills most essential for interns and concluded that the curriculum should focus on: role modeling, selecting and optimizing teachable moments, thinking out loud, and coaching.

SETTING AND PARTICIPANTS: Sixty-one of our 85 IM, Medicine-Pediatrics, Preliminary Medicine, and Transitional Year interns attended a three-and-a-half hour workshop. By having this workshop in September, it was hoped that most interns would have had an opportunity to teach medical students and identify some challenges in doing so. Coverage of clinical responsibilities was arranged so that all interns except those on nights or vacation could attend. Nine clinician-educator faculty facilitated the small group portion of the workshop.

DESCRIPTION: After completing a pre-curricular survey, interns attended a 75 min, large group session that included: an introduction from the Residency Program Director on the importance of the intern's role in teaching medical students; a discussion from the Clerkship Director on the "Care and Feeding of Medical Students"; an introduction to teaching skills important to interns; and a discussion and demonstration of the key steps of role modeling. The remaining 2 h of the workshop were spent in small groups consisting of four to seven interns and one facilitator. The small group format for "teachable moments" and "thinking out loud" included a question and answer session about use of each of these skills, a brief didactic about how to use the skills, an example case script demonstrating each skill, and an opportunity for group members to practice each skill in an observed role play. After the teachable moments and think out loud sections, facilitators briefly discussed the role of interns as coaches who provide informal, regular, timely feedback. Then, the group brainstormed ways to give effective feedback. Finally, facilitators helped interns to set two teaching goals for the year using the SMART (Specific, Measurable, Attainable, Relevant, Timely) Goals framework. Faculty mentors will follow-up on these goals with the interns at a teaching workshop planned for spring and at their end of the year advising session.

EVALUATION: The pre-curricular survey assessed teaching knowledge, frequency of various teaching activities, and self-reported quality of teaching activities. Eighty-three percent of interns surveyed felt that interns play an important role in the education of medical students, and 89 % felt enthusiastic about teaching. However, 60 % of interns lacked confidence in their teaching ability, 68 % were unsure about teaching expectations, and 69 % did not feel well prepared to teach. Interns will complete the same survey at the end of the intern year to compare changes in teaching knowledge, frequency, and quality. Additionally, this year's interns will be compared to last year's intern class, which completed the same survey but did not receive the curriculum. Additionally, medical student clerkship evaluations of interns include a component about teaching quality which will be compared before and after the curriculum. Finally, intern attendees completed learner satisfaction questions and comments. Overall, interns rated both the large and small group activities highly. Greater than 95 % of interns felt that the large and small group activities around teachable moments, thinking out loud, and coaching were either moderately or very useful, while 87 % of interns felt the role modeling section was moderately or very useful. Additionally, 83 % felt that the workshop "highly" or "very highly" affected the way they think of themselves as medical student teachers, and 85 % felt that the curriculum would change their behavior.

DISCUSSION/REFLECTION/LESSONS LEARNED: With programmatic support including faculty and intern time, an intern teaching retreat is both feasible and well-received. We intend to use the content of this workshop to inform the development of a longitudinal residents-as-teachers curriculum involving two additional interactive workshops, which are slated for the end of the intern year and the middle of the second year of residency.

DEVELOPING QUALITY-CONSCIOUS PHYSICIANS: THE VALUE OF A RESIDENT-LED QUALITY IMPROVEMENT INITIATIVE Alexandra Perel-Winkler; Amit K. Hiteshi; Deepa Zalavadia; Tamara Goldberg. St. Luke's-Roosevelt, New York, NY. (Tracking ID #1937960)

NEEDS AND OBJECTIVES: Implementing quality improvement (QI) initiatives in the outpatient setting is vital for training physicians, particularly within the context of a performance-based health care system. Yet few curricula have effectively utilized residents as project leaders. One major barrier has been the constraint of a rotating-provider schedule. Objectives: 1. To illustrate that empowering residents as leaders in the design and implementation of quality improvement work is a valuable educational

experience. 2. To demonstrate that our resident-led, practice-based quality improvement initiative is feasible amidst a rotating-provider schedule.

SETTING AND PARTICIPANTS: One hundred thirty-eight Internal Medicine residents are divided into quartiles which rotate through a two-week primary care block every 6 weeks. Residents are assigned to one of three urban community outpatient clinics for their continuity practice. At each center, a faculty site director oversees the projects and clinical care team members participate in implementation. Two residents per quartile at each site are designated 'QI leaders' and are responsible for driving the action phase of the curriculum.

DESCRIPTION: Foundation phase: Prior to project implementation, residents participated in faculty-led didactic sessions focused on general principles of quality improvement, and more specifically, the PDSA (Plan-Do-Study-Act) model. Action phase: During week one of the primary care block, residents implement site-specific PDSA projects addressing a core quality indicator. During week two, results are analyzed in small group learning sessions, and new PDSA projects are generated for the upcoming block. While all residents participate, the QI leaders are responsible for PDSA selection, coordination with residents and staff, data collection and analysis, and project 'hand-offs' to the upcoming block leaders. In order to better understand project feasibility and the educational value of this leadership role, we developed a survey tool addressed to all QI leaders.

EVALUATION: Using a self-designed questionnaire, we surveyed fellow QI leaders after the completion of the first action phase of the project to assess: attitudes, project feasibility, QI knowledge, and communication. The overall response rate was 18 out of 21 resident leaders (86 %). Favorable attitudes towards QI projects increased from 22 % pre-initiative to 72 % post-initiative. This pilot was considered feasible to lead (83 %) and execute (89 %). Leaders noted improved self-knowledge of design (83 %) and implementation (83 %) of PDSA's after partaking in the curriculum. Sixty-five percent felt inter-block communication between residents was improved, while half felt the project increased intra-block communication.

DISCUSSION/REFLECTION/LESSONS LEARNED: Within the context of a rotating-provider schedule, our resident-led quality improvement initiative appears feasible and educationally valuable. Our results strongly suggest that integrating this leadership model into a trainee curriculum can improve attitudes toward QI work, increase knowledge of practice improvement, and augment resident QI exposure without oversaturating their schedules. Of note, while this continuous PDSA cycle format provides a simple structure and appears to improve inter-block communication among residents, intra-block communication barriers should be explored further. In sum, as more Internal Medicine programs adopt a 6 week inpatient-2 week outpatient schedule, our rapid-cycle PDSA curriculum highlights a viable way to enhance resident training and create quality-conscious physician leaders.

DEVELOPMENT OF A BEDSIDE TEACHING SERVICE TO ENHANCE PHYSICAL EXAMINATION AND CLINICAL REASONING SKILLS Lisa Altshuler; Danise Schiliro; Douglas Bails; Patrick M. Cocks; Ellen Cogen; Jesenia Fernandez; Margaret Horlick; Michael Janjigian; Louis H. Miller; Valerie Perel; Sondra Zabar. NYU School of Medicine, New York, NY. (Tracking ID #1938440)

NEEDS AND OBJECTIVES: Deficiencies in physical examination skills among medical students, residents and even faculty have been documented for decades. Residents also are spending less time in educational activities and in direct patient care. Recent studies have suggested that with the new work hour rules, interns spent only 12 % of their time in direct patient care. With decreases in length of inpatient stays, patients are being discharged with more complex follow-up needs, highlighting the need for effective communication with outpatient providers. Bedside teaching offers the opportunity to develop and strengthen clinical skills, including physical diagnosis, clinical reasoning and communication skills. Additionally, the importance of clear, targeted verbal and written communication of care plans and clinical needs is essential to patient safety and good clinical care. We designed a focused 2 week rotation addressing these educational needs.

SETTING AND PARTICIPANTS: We designed an inpatient rotation at Bellevue Hospital Center, a public hospital. First and second year Internal Medicine residents at New York University School of Medicine were participants, with two first year and one second year resident per 2-week rotation. To date, 45 residents have completed the rotation.

DESCRIPTION: Based on focus groups, surveys, in-depth interviews of faculty and residents, and literature reviews, a 2-week inpatient rotation was designed and implemented to 1) to improve physical diagnosis, clinical reasoning and written and oral communication abilities in residents, 2) strengthen attending

faculty's comfort with teaching these skills. The rotation utilizes two 90-minute daily bedside teaching, and targeted physical examination and clinical reasoning sessions daily, at least one delivered by "master clinicians" and supported by attending faculty. Daily direct observation and detailed feedback of resident performance in these domains supports learning.

EVALUATION: An evaluation model was developed linking resident skill on performance-based measures of clinical reasoning and communication to quality of care outcomes. Resident measures including physical examination skill (adapted mini CEX) and retrospective pre-post measure of perceived skill, and quality of discharge summaries, are being tracked post-intervention to assess maintenance of effects. Patient level outcomes include length of stay, readmissions, patient satisfaction and disease-specific measures. Impact of master clinician teaching on attending faculty is being assessed as a faculty development effort, thus broadening the curriculum's reach.

DISCUSSION/REFLECTION/LESSONS LEARNED: Initial results suggest the curriculum is well received by learners and faculty. The opportunity for deliberate modeling of physical examination skills and connection of examination results to clinical reasoning pathways by master clinicians provides unique training that is unavailable in other settings. This model for assessing the curriculum outcome can contribute to efforts to link curriculum, clinical care and health outcomes in general.

DEVELOPMENT OF A NOVEL PRE-CLINICAL MEDICAL SPANISH PROGRAM AT ONE UNITED STATES MEDICAL SCHOOL Danielle Dougherty¹; Louisa Holaday¹; Jonathan Waldmann¹; Zahra Dawson¹; Joel Purkiss¹; Angad Singh²; Lauren Rodriguez⁴; Nathan Stern³; Stephanie Eldred¹; Ali Dulchavsky¹; Sarah Bell¹; Tomas Huerta¹; Elizabeth Feenstra¹; Nita Valikodath¹; Rajesh Mangrulkar¹. ¹University of Michigan, Ann Arbor, MI; ²University of Washington, Seattle, WA; ³University of California - San Francisco, San Francisco, CA; ⁴Henry Ford Hospital, Detroit, MI. (*Tracking ID #1940164*)

NEEDS AND OBJECTIVES: The Latino population in the United States faces many cultural and linguistic barriers to health care, contributing to poorer health outcomes when compared to their non-Latino counterparts. Research has shown that language barriers between patients and their providers adversely impact the quality of care the patients receive and result in longer hospital stays, more medical errors, and lower patient satisfaction. Latinos are the largest ethnic minority in the US, comprising 16 % of the population, and 30 % by the year 2050. There is not expected to be a proportionate increase in Spanish-speaking physicians, which suggests an alarming rise in language-related health care disparities. Even now, in California, there are 318 physicians per 100,000 English-proficient patients while there are only 38 Spanish-speaking physicians per 100,000 LEP Latinos.^{4,5} Thirty-three percent of Spanish-speaking persons in the United States report speaking English less than "very well,"³ and thus the need for Spanish-speaking, culturally competent physicians is apparent and increasing. A 2005 systematic review found that cultural competence training improves knowledge, attitude, and skills of health professionals and impacts patient satisfaction.

SETTING AND PARTICIPANTS: The University of Michigan Medical School (UMMS) Medical students in their pre-clinical years are taught by a professional Spanish instructor in a small classroom twice a week. The faculty advisor, a native Spanish-speaker dedicated to the program, also attends the class to provide valuable clinical insight, answer questions, and provide feedback.

DESCRIPTION: The pilot year was 2010–2011, and after 3 years of further development, overseen by the Medicine in Spanish Student Curriculum Committee (MSCC) and through feedback and guidance from the Office of Medical Student Education (OMSE) and the Curriculum Planning Committee (CPC), the course has been finalized as a for-credit pre-clinical elective for 2013–2014, the first at UMMS. There are two cohorts of 14 students, who receive 2.5 h of class/week for 15 weeks total. The curriculum was designed to mirror the M1 course schedule, using organ-based systems with cultural-competency education interspersed throughout. Students receive a coursepack at the beginning of the course, and additional resources and assignment information is available on a CTools website (a University of Michigan web-based environment used by instructors, researchers and students). Class weeks are as follows: Review (including anatomy and grammar) and general history and physical questions Cardiology Pulmonology Endocrine and Renal Neurology Psychiatry Folk Illness and Household Remedies Musculoskeletal Oncology Gastrointestinal Reproductive and Genitourinary Informal simulated patient interview Practice weeks with trained Spanish-speaking community members. Students are required to shadow a Spanish-speaking interpreter in the hospital for one half-day to give students the opportunity to witness a physician encounter in Spanish and also to gain experience in using an interpreter, a skill that will certainly be needed in the future for other non-English patient encounters. Overseen by the Faculty Advisor, students develop an educational session for Spanish-speaking community members

EVALUATION: Students are evaluated using three quizzes, one final exam, and a final Standardized Patient Interview in Spanish using SPIs trained through the rigorous University of Michigan program. These interviews are graded using a rubric that was developed with the assistance of the Standardized Patient Program at UMMS. Students provide feedback on the class each week using the same forms that are utilized for feedback on all pre-clinical classes at UMMS and two student focus groups are held.

DISCUSSION/REFLECTION/LESSONS LEARNED: In 2010, a pilot course for Medicine in Spanish was initiated at UMMS to help in graduating physicians who are able to provide excellent care in Spanish. It became a formal, for-credit, UMMS-endorsed elective at the end of its third year after many years of development and collaboration between students, faculty, and the administration. Over the course of the first 3 years, many changes were implemented, including redeveloping the curriculum, appointing a faculty advisor, hiring a new instructor, adapting the schedule, developing novel assessments, integrating with existing technology at UMMS, implementing a structured community service project, and ensuring adequate feedback on the course from the students. We are now working on developing and improving additional components of a longitudinal Medicine in Spanish program at UMMS, including the creation of a faculty-led case discussion group for fluent and native speakers in 2012–2013, dedicated space for students in Spanish-speaking clinics in their clinical year, and further development of a Beginner's course, which is currently taught by student volunteers. We are also constantly improving the course's approach to cultural competency.

EDUCATING FOR CHANGE: MEDICAL STUDENTS DEVELOP ORGANIZATIONAL LEADERSHIP SKILLS THROUGH STUDENT-DRIVEN COMMUNITY-BASED FIELD PROJECTS Brent C. Williams¹, Senait Fisseha²; Joy Williams³; Patricia Mullan⁴. ¹University of Michigan, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI; ³University of Michigan, Ann Arbor, MI; ⁴University of Michigan, Ann Arbor, MI. (*Tracking ID #1929187*)

NEEDS AND OBJECTIVES: Leadership training in medical education is now widely recommended, though consensus is lacking on the appropriate scope and best methods for leadership curricula. A central goal of our newly created Global Health and Disparities (GHD) co-curriculum is to "prepare medical students to be agents of sustainable change to reduce domestic and global health disparities". Therefore we developed an experiential leadership curriculum focusing on working with and developing organizations to promote change to address health disparities. Learner objectives are to: a) identify personal characteristics related to effectiveness as an organizational leader, and b) build, critique, and refine a collaborative project to address health disparities using frameworks and processes of demonstrated effectiveness in team and organizational development, and c) develop a personal learning plan for becoming a more effective leader.

SETTING AND PARTICIPANTS: 34 1st year medical students enrolled in the GHD co-curriculum at the University of Michigan during 2013–14, and 9 community-based organizations in a 60-mile radius of the medical campus. All GHD activities are in addition to the formal medical school curriculum.

DESCRIPTION: The GHD co-curriculum consisted of three main components: • *Field projects with community-based organizations (CBOs).* Groups of 3–5 students contacted selected CBOs to design and implement a new project or program over 7 months, of immediate value to the CBO and/or its constituents. CBOs were coached to co-design the intervention with the students. A total of 9 CBOs were recruited to participate, and included community health centers, a rural psychiatry outreach program, free clinics, school-based clinics, and the UM Community Outreach Program. • *Four two-hour seminars.* Instructional methods included discussions with organizational leaders in health disparities, student-led case studies, and field team discussions and presentations applying key concepts. Conceptual frameworks for team and organizational leadership are based on: a) stakeholder analysis (including collaborators, customers, suppliers, and external stakeholders), b) the GRPI (Goals – achieving consensus on clear, achievable goals; Roles – distribution of authority, responsibilities, and tasks; Processes – decision-making, scheduling, communication; and Interactions – managing interpersonal relations) model of team development, and c) Community Based Participatory Research (CBPR), with its focus on joint decision-making, power-sharing, and mutual accountability across academic-community partnerships • *Final presentations to CBOs and GHD.* Student teams present a 'deliverable' to the CBO and, in a separate session, a description of the project and lessons learned to GHD students and faculty.

EVALUATION: Program evaluation will include: • Pre- and post-intervention surveys of students' self-rated leadership skills using the validated *Empowerment Leadership Questionnaire*. • CBO leadership interim and final online surveys and phone interviews measuring program processes and outcomes, effects on the CBOs, and ratings of individual and groups of students. • Review of students' interim

written assignments for inclusion of key concepts. • Final project write-up evaluation of project completion rates, inclusion of key concepts in project descriptions, reflections that include practical applications of lessons learned.

DISCUSSION/REFLECTION/LESSONS LEARNED: The scope and methods of current leadership curricula vary widely among medical schools; many curricula focus on team function in medical practice, and are classroom or short-exercise based. In contrast, our curriculum is intended to focus on organizational leadership to foster change. Guiding principles are that: a) leadership is learned mainly by *doing* with structured reflection and feedback rather than learning without an authentic context, b) learning about change agency requires that students engage in risk-taking by developing and testing new ideas rather than observe existing organizational operations, and c) building genuine collaborations across differing cultures and organizations that includes structural and process-based attention to accountability and shared decision-making is essential to leadership skills development. Challenges include: a) keeping students' time burden manageable while engaging them with (at times distant) CBOs, and b) creating and maintaining opportunities for new projects each year among a diverse network of voluntary CBOs, and c) securing faculty time to implement and evaluate the leadership curriculum.

EVALUATING COMPATIBILITY MATCHING IN A COMBINED INTERNAL MEDICINE AND PEDIATRICS RESIDENCY MENTORING PROGRAM

Daniel McFarlane^{1,2}; Curt Walker¹.¹The Ohio State University Wexner Medical Center, Columbus, OH; ²Nationwide Children, Columbus, OH. (*Tracking ID #1936648*)

NEEDS AND OBJECTIVES: Medical residency training is a challenging period when residents make important decisions that steer the direction of their careers. It can be difficult to determine which experiences serve as validation of career goals and which experiences aid in personal growth. Mentoring relationships have often served the function of providing personalized guidance and support to individuals in these learning contexts. Although studies on formal mentoring relationships have encompassed numerous professional contexts, few have examined components of compatibility between medical trainees and professionals and their effect on the success of the mentoring relationship. This is the aim of our study.

SETTING AND PARTICIPANTS: The current initiative aimed to develop a multidimensional matching process using components of compatibility based on demographics and personal preferences to pair combined internal medicine and pediatrics (Med-Peds) residents with similarly trained attending physicians. We assessed relationship outcomes associated with the matching process to determine the role of compatibility in realizing mentoring benefits.

DESCRIPTION: Outcomes of a structured mentor program that paired one Med-Peds resident (nResident = 19) with one attending physician (nMentor = 19) were compared to those of a class based mentor program (1 mentor paired with 8–10 residents; nClass = 17). Enrolled residents and volunteer mentors were given a survey that assessed demographics, personal interests, values, and professional goals. All mentors were Med-Peds trained despite representing different professional specialties. We derived compatibility scores from a combination of weighted survey responses and randomly assigned trainees to either a matched or unmatched group to test the role of compatibility in mentoring outcomes. The matched group (nMatched = 10) paired residents with the corresponding mentor who received the highest compatibility score. The unmatched group (nUnmatched = 9) randomly paired residents with the remaining mentors regardless of compatibility score. Mentors and residents were kept blind of their assignments and the purpose and expectations of the program were explained to all participants.

EVALUATION: We administered a program evaluation survey after 1 year to assess differences in relationship outcomes. Results of a series of z-tests for proportions showed supportive, yet non-significant trends in resident outcomes for matched mentor pairs compared to class based and unmatched pairs. Data were not sufficient to assess differences in mentor outcomes.

DISCUSSION/REFLECTION/LESSONS LEARNED: Matching residents with mentors provides a foundation of compatibility that can facilitate stronger more fulfilling mentoring relationships versus random assignment. Compatibility based on professional goals was most sought after, followed by personal interests. We continue to enroll new residents and mentors (nResident = 29) to further investigate the role of compatibility in mentoring outcomes. Personality typing was also considered as a foundation for compatibility and we intend to study if matching based on personality type would provide stronger outcomes. Based on our data, full benefits of a mentoring relationship were not realized in either group. Therefore, future steps include targeted education to develop mentoring skill sets as well as to ensure that mentees are receptive to mentor guidance.

EVALUATION OF THE MAINTENANCE OF COMPETENCY PROGRAM: PILOT YEAR 1 Nancy Stewart; Nicole M. Twu; Frank Zadravec; Meredith Borak; Dana P. Edelson. The University of Chicago, Chicago, IL. (*Tracking ID #1940145*)

NEEDS AND OBJECTIVES: Approximately 200,000 patients experience a cardiac arrest in United States hospitals each year, with a mortality rate of over 80 %. Cardiopulmonary resuscitation (CPR) is the mainstay of therapy for these patients but CPR is a complex psychomotor skill that is difficult to perform well. The standard of care for training and certification in this lifesaving skill is biannual, instructor led courses. Yet, prior research suggests that the skills developed in training decay well before the end of the two-year certification period, with the most rapid skill decay occurring within the first 6 months. We sought to test the feasibility of a program of self-service, quarterly training in Basic Life Support (BLS), as an alternative to in-person biannual bolus training.

SETTING AND PARTICIPANTS: All nurses and nursing assistants caring for adult patients at the University of Chicago were eligible to participate. The study was jointly supported by the American Heart Association (Dallas, TX) and Laerdal Medical (Stavanger, Norway) and was approved by the University of Chicago Internal Review Board. Participation was voluntary, with written consent, but subjects were offered a \$5 gift card upon completion of the 1st and 4th quarters.

DESCRIPTION: The University of Chicago served as a pilot site for the Resuscitation Quality Improvement (RQI) program developed jointly by the American Heart Association and Laerdal. The program involved the use of specially designed self-service CPR mannequins sitting on top of mobile carts connected to laptop computers. These carts were placed in close proximity to clinical areas to enable participants to interact with the system during breaks as each quarterly module was designed to require less than 10 min to complete. Modules alternated between psychomotor skills stations, requiring participants to perform chest compressions and/or assisted ventilation, and cognitive modules. Participants received reminder emails when they were due to complete a new module. If more than 6 months lapsed between modules the subjects were deemed to have dropped out. These subjects were then surveyed to assess barriers to participation.

EVALUATION: Following the open enrollment period, 123 participants were consented. Sixty-three (51 %) of participants completed Q1, 41 (33 %) of participants completed Q2, 50 (41 %) of participants completed Q3 and Q4. Of the 123 study participants, 44 completed the post-drop out anonymous survey, and of those, only six respondents stated they completed at least one module. Forty-one (93 %) of respondents primarily works day shifts. Thirty-six (82 %) respondents thought the MOC would be more convenient. Twenty-three (52 %) respondents thought the MOC would help maintain their skills. Survey results determined major barriers to completion included a lack of time to leave clinical responsibilities 36 (82 %), difficulty actively compressing the manikin 18 (41 %), and a lack of administrator support including reminder e-mails/notifications 17 (39 %).

DISCUSSION/REFLECTION/LESSONS LEARNED: This pilot program demonstrated the difficulties encountered in implementing a self-service training model during clinical work. Avoiding a full day course every 2 years may not be sufficient incentive for clinical care providers to switch to a new training modality. Successful implementation of such a program may require a mandate and/or additional incentives. Also, combining instructors with the carts to actively encourage participants to interact with the system could potentially maximize participation. Finally, alternative ways to engage nursing staff in the program will need to be evaluated, such as integrating the MOC during other nursing requirements.

FLIPPING THE CLASSROOM INTO THE HOSPITAL: INTERACTIVE CONTENT TO INTEGRATE BASIC SCIENCE INTO THE CLERKSHIP Charles D. Magee; Lynn Byars. Uniformed Services University, Bethesda, MD. (*Tracking ID #1939408*)

NEEDS AND OBJECTIVES: Our university has undertaken curricular reform, aiming to integrate clinical and basic sciences into an 18-month pre-clerkship, 12-month clerkship, and 18-month post-clerkship model. The pre-clerkship curriculum consists of a modular, systems-based introduction to basic and clinical science. The new pre-clerkship timeframe was truncated to 18 months, resulting in a substantial reduction in contact time with the basic science faculty. The clerkship curriculum consists primarily of traditional inpatient and outpatient clinical experiences. Basic sciences were identified as threads to be integrated across the entire curriculum. Prior to curriculum reform, basic science concepts were minimally integrated into our internal medicine clerkship. We aim to develop an effective method for integrating basic science concepts into the clerkship setting while harnessing the expertise of our

basic science faculty to improve clinical performance measures. Objective: To deliver interactive, self-paced, instructional material to solidify key basic science concepts immediately preceding integrated clinical teaching activities via: - Collaboration with basic science faculty to develop expanded educational roles into the clerkship setting; and - Development of educational activities that align clinical and basic science knowledge in internal medicine clerkship educational objective.

SETTING AND PARTICIPANTS: Our university is a US allopathic medical school with clerkship students rotating in hospitals across the United States. This innovation is designed for clerkship students rotating on both ambulatory and inpatient internal medicine.

DESCRIPTION: The internal medicine clerkship implemented weekly interactive group sessions (IGS), which are case-based discussions of internal medicine topics led by a clinician-educator. The learning objectives for each IGS session include approximately 20 % basic science material. An identified challenge to successful IGSs is that the physicians who deliver all didactic material are typically less facile at basic science instruction. Additionally, our students complete clerkships at sites across America, making direct contact time with basic science professors impossible to realize in all clerkships. Collaborating with basic science faculty, basic science objectives are being converted into web-based didactic sessions to precede the IGS topic. Each session has 10–15 min of online material featuring narrative and interactive slides, embedded video and animation, and formative quiz questions to allow assessment of content mastery.

EVALUATION: For the innovation pilot, we are tracking timing of module completion prior to each IGS, time spent on the module, number of times accessed, and answers from pre-, post-, and embedded quiz questions. Surveys of students and faculty will assess satisfaction and perceived value with this innovation. Qualitative comments will be analyzed for themes that can direct the development of future content.

DISCUSSION/REFLECTION/LESSONS LEARNED: “Flipping the classroom” is an educational technique to allow student mastery of required knowledge prior to participation in expert-led synthetic activities. This offers a solution for meaningful integration of basic science content into the clerkship. This innovation allows basic science faculty to reach learners outside the classroom. Our basic and clinical scientists have welcomed this innovation. Our innovation aims to foster integration by delivering basic science expertise to the clerkship environment for transfer and synthesis of basic science knowledge to patient care.

GERIWARD FALLS: AN INTERPROFESSIONAL TEAM-BASED CURRICULUM ON FALLS PREVENTION AND SYSTEMS-BASED CARE FOR THE HOSPITALIZED OLDER ADULT ¹Stephanie Rennke¹; Claire Larson¹; Julie Vavuris³; Vicki Jue²; Joscette Rivera¹; Betty Smoot⁴. ¹UCSF, San Francisco, CA; ²UCSF, San Francisco, CA; ³UCSF, San Francisco, CA; ⁴UCSF, San Francisco, CA. (*Tracking ID #1939775*)

NEEDS AND OBJECTIVES: Interprofessional collaboration is key for both student education in geriatrics and in the care of older adults, but is often underemphasized in medical education. Falls are a source of significant morbidity and mortality in the geriatric population. GeriWard Falls is an interprofessional team-based curriculum for health professions students to conduct a comprehensive falls risk evaluation at the bedside. The objectives included: 1) identify epidemiology and risk factors for falls; 2) work as a team to perform a focused inpatient falls risk assessment; and 3) propose a systems-based intervention to prevent falls.

SETTING AND PARTICIPANTS: The curriculum was piloted at a large academic medical center with patients over 65 years admitted to the medicine or cardiology service. Health professions students on clinical rotations in the hospital participating in the pilot included third-year medical, fourth-year pharmacy, third-year physical therapy, and graduate level nursing students.

DESCRIPTION: Interprofessional teams of 4–5 students met for a 2 h exercise which consisted of three parts: 1) a 90-minute bedside clinical exercise and completion of a bedside falls assessment, interviews with patient, caregivers and staff, physical examination and medication review; 2) development of a falls care plan and direct written communication with the patient and the primary inpatient medical team regarding prevention strategies and 3) propose systems-based interventions to reduce fall risk. Following the clinical exercise the students discussed their recommendations with a nursing, pharmacy or medicine faculty facilitator, and then contacted the primary medical team with their recommendations. The facilitators scored the student teams using a rubric on their falls assessment worksheet, system-based interventions proposal, and oral presentation.

EVALUATION: Twenty-three students participated in a pilot session in October 2013. Using a 5-point Likert scale, over 90 % of students agreed or strongly agreed that they learned skills applicable to future practice. Faculty rated the student presentations highly, citing the students’ ability to effectively collaborate, identify risk factors for falls, and propose systems-based interventions. The primary medical teams found the recommendations useful, and planned to implement at least one of the recommendations detailed in the student team’s falls care plan. On the post session survey completed by students, the score range for each component was 4–5 (“very good” to “excellent”) including: usefulness of the activity, overall quality of the session and likelihood that students will make changes in clinical activities.

DISCUSSION/REFLECTION/LESSONS LEARNED: GeriWard Falls is an innovative curriculum that emphasizes interprofessional collaboration during a clinical encounter with a hospitalized older adult. The activity was engaging for students, and helped them achieve competency with fall risk assessment. Communication of the students’ assessment to the primary medical team was not only useful to the primary team, but also helped students understand how systems can affect patient care.

GIVING EARLY MEDICAL STUDENTS A “HOME”: STUDENTS CAN MEANINGFULLY CONTRIBUTE TO CARE ON A YEAR-LONG CONTINUITY ROTATION IN A PCMH ¹Jennifer Mackinnon; Martin Muntz; Julie L. Mitchell. Medical College of Wisconsin, Milwaukee, WI. (*Tracking ID #1940081*)

NEEDS AND OBJECTIVES: To integrate early students into the Patient Centered Medical Home (PCMH). To develop a robust list of level-appropriate clinical tasks for early students that concurrently contribute to high quality patient care and advance learner knowledge and skills.

SETTING AND PARTICIPANTS: Our institution pairs a student with a preceptor in a year-long continuity course spanning the second half of the first year and the first half of the second year. Recruiting preceptors is a challenge that can be turned into an opportunity once appropriate clinical tasks are identified to advance the goals of the medical home and student education. To identify these tasks, the authors conducted local and regional workshops consisting of community and academic preceptors in internal medicine, pediatrics and family medicine. Sharing personal experiences, attendees added to the task list after considering principles of a medical home and evidence-based examples of how students can contribute. Sixty-seven physicians (including a fraction of residents) participated in the workshops. After removing duplicates and combining related ideas, 37 tasks were categorized within the PCMH standards. Examples include items related to specific history-taking and exam (such as standardized templates and blood pressure retakes), between-visit care (such as sharing results and ensure instructions were followed), connections to community agencies and strategies during transitions.

DESCRIPTION: Inspired by our list of clinically and educationally meaningful tasks for early students, we prepared students assigned to PCMH preceptors to contribute to care in a pilot program. Ten early students were provided an introduction to the PCMH and tools within our EHR, protocols to manage a diabetes registry, and a review of key preventive health guidelines. They were also given instructions on chronic condition management, including a pre-visit planning checklist. Students then worked within their preceptor-led clinic team in the continuity course. Preceptors were given independence in selecting specific clinical tasks they expected their students to master.

EVALUATION: We developed a robust list of tasks relevant to the early student that also allows students to contribute to care, setting up early students as valuable team members for preceptors in a PCMH. This value-added task list, which was generated with the help of both junior and more experienced physicians representing each of the primary care specialties, provides a “menu” of options to individualize teaching and add value for different teachers, learners, and patient populations. To our knowledge, this is the first list of PCMH-related tasks for early students.

DISCUSSION/REFLECTION/LESSONS LEARNED: Despite creating a list supported by a consensus of preceptors, we found individual preceptors widely varied in their expectations of students, based on their personal practice priorities and their own experience with items on the task list. Some preceptors voiced disagreement with students performing tasks that could be performed by other team members, and some preceptors were not proficient enough with the EHR tools and registry protocols to model use to students. Institutional educational leaders will use the task list and preceptor and student reactions to it to tailor preceptor preparatory materials and recruiting strategies. Further work will include the feedback of medical students currently enrolled and those recently graduated from this new program.

GOALS OF CARE AMBULATORY RESIDENT EDUCATION (GOCARE), A PILOT CURRICULUM Marianne Camargo^{1,3}; Jacqueline K. Yuen²; Stephen Berns²; Diane E. Meier². ¹Rutgers, New Jersey Medical School, Newark, NJ; ²Mount Sinai Hospital, New York, NY; ³Mount Sinai Hospital, New York, NY. (*Tracking ID #1900318*)

NEEDS AND OBJECTIVES: Goals of care discussions frequently occur in the hospital setting, often after patients have lost decision making capacity, leaving health care providers and surrogates to make difficult treatment decisions with limited understanding of patients' treatment preferences. This follows from missed opportunities to have advanced care planning (ACP) discussions with patients and their families in the outpatient setting. To address this gap, we piloted a curriculum to: 1. Enhance residents' understanding of the importance of ACP in the ambulatory care setting. 2. Improve residents' communication skills during outpatient ACP discussions. 3. Facilitate documentation of ACP discussions using the electronic medical record (EMR).

SETTING AND PARTICIPANTS: Second year Internal Medicine (IM) residents ($N=42$) participated in the GOCARE curriculum as part of their 4-week ambulatory block from January to June 2013 at an urban, academic ambulatory care practice.

DESCRIPTION: The GOCARE curriculum content was guided by a focus group of IM residents on their communication training needs, a literature review of ACP communication strategies, and instruction from content experts. The instructional method was modeled after a workshop associated with improved communication skills for oncology fellows. It included didactics, a demonstration role-play by faculty, and a communication lab using trained simulated patients and family members for skills practice. The curriculum was delivered through weekly small group sessions of 6–9 residents led by 2 faculty members. In addition, residents completed at least one outpatient visit focusing on ACP discussions with 1–2 patients from their continuity panel who had chronic disease and a high likelihood of hospitalization. The (EMR) was re-configured to facilitate documentation and accessibility of ACP discussions.

EVALUATION: We used paired pre/post surveys to assess residents' self-rated preparedness for communication challenges during outpatient ACP discussions before and after GOCARE. The survey used a descriptive 7-point Likert-type scale to rate the level of resident preparedness to perform the following: discuss health care proxy designation, deliver bad news, engage in ACP discussions, discuss treatment options with seriously ill patients and/or their families, elicit goals of care, discuss prognosis, and discuss hospice care. After GOCARE, the mean rank for all seven items increased 1–3 points on the scale, and this change was statistically significant ($p<0.001$) for all comparisons. In addition, we compared residents' willingness to initiate specific ACP discussion topics with patients and their families in the ambulatory setting. After GOCARE, more residents were willing to initiate conversations regarding goals of care (61 % vs. 93 %, $p=0.002$), treatment options, including comfort care (54 % vs 90 %, $p<0.001$), preferences on life-sustaining treatments (68 % vs. 93 %, $p<0.001$), and resuscitation preferences (63 % vs. 93 %, $p=0.006$). Furthermore, 95 % of residents had documented ACP conversations in the EMR for at least one patient during the course of the curriculum.

DISCUSSION/REFLECTION/LESSONS LEARNED: This pilot curriculum was created to improve residents' understanding, attitudes and communication skills during outpatient ACP discussions. We found that residents' self-efficacy with ACP discussion significantly improved after GOCARE. However, we did not use an objective method to rate change in communication skills. In the future, we plan to utilize pre-post curriculum OSCEs with standardized patients to objectively assess change in residents' communication skills.

HANDOFF TRAINING FOR MEDICAL STUDENTS: EFFECTIVENESS AND SUSTAINABILITY OF KNOWLEDGE Christopher J. Smith; Grant Peterson; Gary L. Beck. UNMC, Omaha, NE. (*Tracking ID #1938318*)

NEEDS AND OBJECTIVES: The transfer of patient care between healthcare providers is a vulnerable time for patient safety. Incomplete handoffs can lead to adverse outcomes, yet few medical schools provide formal instruction on handoffs. The limited research evaluating handoff curricula for medical students has not examined the sustainability of acquired skills. To address these issues we developed a workshop to instruct senior medical students on handoff communication and examined its impact on participants' immediate and extended attitudes and

knowledge. The objectives for workshop participants were to: 1. Understand how poor communication during transitions of care impacts patient safety. 2. Identify key elements of effective handoff communication. 3. Demonstrate a standardized strategy for written and verbal handoff communication.

SETTING AND PARTICIPANTS: The intervention took place at a large, state-funded university in February and April 2013. An elective workshop in handoff communication was offered as part of residency preparatory program for senior medical students. Up to 12 students could participant in each session.

DESCRIPTION: During the 4-hour workshop, best-practices for handoff and discharge summary communication were reviewed. Following a brief didactic session, participants applied their skills to clinical scenarios in interactive small groups. Large group discussions were utilized to reflect upon the exercises and generate discussion.

EVALUATION: Participants' attitudes and knowledge were tested pre- and post-intervention. A follow-up test was sent to participants and a control group in June 2013 to evaluate retention. Those completing the follow-up test received a \$10 gift card. Attitude-based questions were rated on a 5-point Likert scale. Knowledge was tested with multiple choice questions and open-ended responses to clinical vignettes. Vignettes were scored on a 10-point scale by two blinded faculty members, with disagreements settled by consensus. Materials were tested for clarity prior to distribution. Twenty-four students participated in the seminar. All participants took the pre- and post-tests, and there was significant improvement in 12 of 13 attitude-based questions, 4 of 9 knowledge-based multiple-choice questions, and clinical vignette scores. Sixteen seminar participants and 21 control-group students took the follow-up test. Eleven participants completed vignette questions for all three tests. There was significant improvement between pre- and post-tests (6.34 vs. 8.55, $p<0.001$), but this improvement decreased in follow-up (7.45). Only the April cohort maintained a significant improvement through follow-up testing ($W=0.831$, $p=.003$). There was no difference in follow-up vignette scores between seminar participants and the control group.

DISCUSSION/REFLECTION/LESSONS LEARNED: Students' attitudes and knowledge improved immediately following handoff training, but gains in knowledge declined in the following months. This is likely because students did not have the opportunity to routinely apply these skills in a clinical context. These findings support that, while handoff training is effective in improving attitudes and knowledge, it should coincide with assumption of clinical responsibilities.

HEALTH LITERACY IN TRANSITIONS OF CARE: AN INNOVATIVE OBJECTIVE STRUCTURED CLINICAL EXAMINATION FOR FOURTH YEAR MEDICAL STUDENTS Reena Karani¹; Kimberly Bloom-Feshbach¹; Dana Casey¹; Lucy Schulson¹; Jonathan Gifto²; Peter Gliatto¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Albert Einstein College of Medicine, Bronx, NY. (*Tracking ID #1937013*)

NEEDS AND OBJECTIVES: Only 12 % of Americans are considered to have proficient health literacy. Low levels of health literacy have been associated with multiple adverse outcomes. Recent evidence also indicates that low health literacy is a risk factor for hospital readmission. As part of a health literacy curriculum at the Icahn School of Medicine at Mount Sinai, we designed and implemented an innovative Objective Structured Clinical Examination (OSCE) to assess fourth year medical students' ability to appropriately screen, counsel, and provide discharge instructions to patients of limited health literacy. Other institutions have implemented health literacy standardized patient encounters. Our OSCE is unique in that it a) focuses on the hospital discharge process, b) assesses fourth year medical students as part of an internship preparatory clerkship and c) specifically evaluates the efficacy of an evidence-based health literacy workshop.

SETTING AND PARTICIPANTS: Between January and April 2014, all fourth year students ($n=140$) will undergo the Health Literacy in Transitions of Care OSCE with trained standardized patients (SP).

DESCRIPTION: In the OSCE, the fourth year student will prepare a patient for a safe hospital discharge. As part of this process, the student must screen the patient for low health literacy and educate the patient about diagnosis (pulmonary embolus), management (oral anticoagulation), and outpatient follow-up (INR monitoring). The student will also be required to write discharge instructions appropriate for patients of low health literacy. In order to allow for future research on the relationship between student participation in an evidence-based health literacy workshop and performance on the OSCE, 40 % of the class will serve as a control, receiving the workshop following administration of the OSCE.

EVALUATION: To assess a student's ability to communicate with patients of low health literacy, the trained SP will complete a checklist. The checklist includes student

performance on the following items: health literacy screening, use of plain language, delivery of a focused message, and teach-back, among other evidence-based communication techniques. The Flesch-Kincaid readability tool will be utilized to assess the reading level of the student's written discharge instructions. The encounter will also be video recorded to assess inter-rater reliability between trained scorers. For feedback, each student will view his or her graded checklist and discharge instructions. After data collection is complete, we will assess the relationship between workshop participation and performance on the OSCE.

DISCUSSION/REFLECTION/LESSONS LEARNED: Transitions of care are a particularly vulnerable time for all patients. The Health Literacy in Transitions of Care OSCE is an innovative tool to train future interns to identify and better communicate with patients of all health literacy levels during the hospital discharge process. Curricula such as ours may ultimately make this time safer and improve health outcomes. *KBF, DC, and LS contributed equally and should be considered co-first authors

HOME VISITS FOR MEDICALLY COMPLEX PATIENTS IN A TERTIARY ACADEMIC MEDICINE CLINIC AS A TOOL FOR RESIDENT EDUCATION AND READMISSION PREVENTION Duncan Vincent; Paul Chelminski. University of North Carolina Hospitals, Chapel Hill, NC. (*Tracking ID #1897469*)

NEEDS AND OBJECTIVES: Home visits are a much-valued but under-utilized way to provide care. Historically, providers have offered these in urban settings for logistical ease. We developed a multi-modal educational and clinical initiative with three principle aims: provide structured care outside of a standard clinic visit; provide rapid post-hospitalization follow-up for a subset of patients to decrease readmissions; and integrate resident physicians into this process as practitioners and learners.

SETTING AND PARTICIPANTS: The Charles Sanders Clinical Scholars Grant was created to promote personalized and humanistic medical care at the University of North Carolina at Chapel Hill as part of the educational mission. The first recipient of the award (an attending clinician educator) developed a home visit program that integrated resident physicians. Residents on ambulatory blocks accompanied the attending on home visits. The population consisted of established patients in the UNC Internal Medicine Clinic, which is a blended faculty and resident practice. Shortly after its inception, the program expanded to make the resident the lead physician in an initiative to decrease readmissions of recently discharged, high risk patients.

DESCRIPTION: Home visits were arranged by a multidisciplinary team including a social worker. They were conducted by the attending physician and usually one resident physician (sometimes a pharmacy resident). Residents were the lead physician for hospital follow-up visits. Medication reconciliation occurred at each visit with direct inspection of the patient's pill bottles. Patients received counseling about medication adjustment, new prescriptions, laboratory, or imaging studies. Almost all visits were billed. After the visit, residents wrote a brief reflection of the experience. A master map was created of all the home visit locations.

EVALUATION: To date, there have been 62 unique home visits and 16 subsequent follow-up visits. Mean age of patients was 70 years (range 29–95 years). Fifty-two percent were male. Mean and median distances traveled round trip were 20 and 13 miles respectively that spanned six counties (range 0–95 miles). Average length of the visit was 30 min (range 10–75 min). Seventy-six percent of patients were insured with Medicare, 16 % with private insurance, 2 % with Medicaid, and 6.5 % were uninsured. Seventy-seven percent of patients were Caucasian and 21 % were African American. The patients were medically complex: 56 % had hypertension, 22 % had congestive heart failure, 29 % had coronary artery disease, 13 % had atrial fibrillation, 17 % had COPD, 16 % had diabetes, and 13 % had depression. Only ten visits (16 %) were conducted outside of usual clinic hours. Twenty-four visits (39 %) were urgent care visits for acute complaints. Ten percent of home visits were conducted for palliative care and hospice monitoring. An internal medicine resident was present for 75 % of the visits. There was a new prescription at 30 % of all visits. Forty-three percent were hospital follow-up visits occurring within 14 days of discharge. Seven percent of these patients were readmitted to the hospital within 30 days of discharge. By comparison, our general medicine clinic population has a 19 % re-admission rate within 30 days. A gift was offered at 17 % of visits. In 20 % of the households, the television was on in the examining space. A sampling of learner reflections after the visits revealed an enhanced appreciation for the social and environmental dimensions of care.

DISCUSSION/REFLECTION/LESSONS LEARNED: Home visits span a broad spectrum of patient encounters, from acute to chronic to palliative care. Interestingly, the median visit duration was not extended when compared to a standard clinic visit. We have demonstrated the feasibility of home visits in a non-urban teaching medical center. They circumvent barriers to prompt, patient-centered care that prevail in the

traditional clinic visit. They can potentially prevent hospital readmissions and decrease resource utilization. Integrating learners into home visits promotes humanism in medicine. Resident-composed reflections emphasize the reciprocal nature of care between patients and providers in this non-time-pressured and non-regimented setting.

HOW PATIENT-CENTERED ARE YOU? THE IMPLEMENTATION AND ASSESSMENT OF A TRAIN-THE-TRAINER SHARED DECISION MAKING CURRICULUM FOR HOSPITAL BEDSIDE ROUNDS Stephanie Rennke¹; Bradley Monash^{1,5}; Rebecca Blankenburg²; Debbie Sakai²; Stephanie M. Harman³; Adeena Khan¹; Clarence H. Braddock⁴; Patrick Yuan¹; Jason Satterfield¹. ¹UCSF, San Francisco, CA; ²Stanford University, Stanford, CA; ³Stanford University, Stanford, CA; ⁴UCLA, Los Angeles, CA; ⁵UCSF, San Francisco, CA. (*Tracking ID #1939726*)

NEEDS AND OBJECTIVES: Patient-centered medical care remains a primary goal of all health care providers and medical centers. Institutions are under increasing pressure to improve patient-centered outcomes, including patient satisfaction, and patients are taking a more active role in their own healthcare. Although the majority of providers believe they practice patient-centered care, patients frequently do not understand their condition or care plan, and their psychosocial characteristics are not considered. One of the primary means for improving the patient-centeredness of the care we provide is through patient engagement and shared decision-making (SDM). The objective of the curriculum is to improve patient engagement and SDM using a multi-modal strategy including train-the-trainer workshops, an educational campaign and expert observations with a real time feedback and audit system.

SETTING AND PARTICIPANTS: The curriculum is being piloted in 2013–2014 over a 6 month period at two large academic medical centers with internal medicine hospitalists, pediatric hospitalists and internal medicine and pediatric chief residents and residents.

DESCRIPTION: We developed a patient engagement and SDM curriculum as a multimodal strategy with three parts: 1) a series of train-the-trainer workshops for residents, chief residents and hospitalist faculty, with interactive exercises and videotaped role plays on SDM using the ASK-INFORM-ASK model; 2) an educational "campaign" and roll out including pocket cards, announcements, posters, reminders; and 3) expert faculty observations with real-time assessment with audit and feedback to the inpatient teams. A validated instrument, the Rochester Participatory Decision Making Scale (RPAD), is being used as a pedagogical tool and as a means to assess physician engagement in SDM. Program evaluation will include retrospective pre-post workshop questionnaires, RPAD ratings, and pre-post patient surveys.

EVALUATION: To date, a total of 20 medicine residents, fellows, and hospitalists have participated in the workshops. All participants showed improved confidence in using SDM tools, with a mean increase of 0.456 on a 4-point Likert scale. Participants rated their knowledge and self-efficacy in SDM higher after participating in the curriculum in all categories. The largest impact was on participants' confidence with inviting patient and family participation in SDM (mean increase of 0.850), followed by confidence with asking about patient/family agreement with the decision and examining the patient's or family's concerns and problems with follow through (mean increase 0.800 and 0.700 respectively). Residents and hospitalist faculty agreed or strongly agreed that they learned skills applicable to future practice. There will be eight additional workshops in 2014, which will train approximately 40 residents and 40 hospitalists prior to the campaign launch and expert observations.

DISCUSSION/REFLECTION/LESSONS LEARNED: This train-the-trainer curriculum, including an educational "campaign" and use of a validated instrument to evaluate SDM at the bedside, is a novel approach to medical education and faculty development and improves learner self-efficacy. Participants were recruited to disseminate SDM and to actively engage other trainees and faculty by role modeling best practices and teaching SDM to the inpatient teams.

IDENTIFYING COMMUNICATION NEEDS FOR PALLIATIVE CARE PATIENTS TO DEVELOP A NARRATIVE BASED EDUCATIONAL TOOL Lindsey N. Clark¹; Henry Mortimer²; Ruth Evans³; Sarah H. Parker¹; William S. Krimsky³. ¹MedStar Institute for Innovation, Washington, DC, DC; ²Mortimer Communications Inc., Baltimore, MD, MD; ³MedStar Franklin Square Hospital, Baltimore, MD. (*Tracking ID #1940054*)

NEEDS AND OBJECTIVES: Communication between patient and physicians is repeatedly recognized as a key component for providing safe, high quality care to patients,

particularly those dealing with chronic illness or requiring palliative treatment. However, only a small percentage of residents/physicians report having communication training. Further, didactic formats such as lectures, or simply shadowing another physician, may not be the most effective method to teach residents adequate communication techniques. Research suggests that medical learners need to be engaged in real patient experiences combined with reflective exercises to optimize communication skills. Combining these two elements into an education tool can lead to a change in behavior for better patient communication. This presentation will center on ongoing work to develop a narrative based education tool that combines actual patient chronicles spanning the arch of disease, from diagnosis through death, in conjunction with reflective exercises to enhance and teach communication skills to residents. This work is innovative as it utilizes actual and longitudinal patient narratives recorded in the healthcare setting, the micro-system where these issues occur. Thus, it can serve as a platform for developing education tools on communication with patients.

SETTING AND PARTICIPANTS: Participants included 26 patients and/or their care-providers with chronic and/or life-altering illnesses receiving treatment at a large urban medical center in Baltimore, MD.

DESCRIPTION: From 2009 through the present, semi-structured interviews were conducted with patients and, whenever possible, with their care-providers, families, etc. The interviews were conducted by a specialist who was treating the patients at the time of the interviews. The interviews were conducted in the office setting, outside of the patient's treatment session. All interviews were videotaped and transcribed. Patients and their care-providers were asked to reflect on their experiences regarding their initial diagnosis, treatment options, and the manner in which physicians relayed information about their health condition. Patients were asked six main questions and also given the opportunity to describe other experiences that were meaningful to them during their care process. To determine specific communication areas that are critical for communication, qualitative analysis using a grounded theory approach will be conducted on the video transcripts. Two researchers will independently code 5 of the interviews. Coding results will be compared and discussed, resulting in a final coding scheme that will be used for all interviews to identify emerging themes.

EVALUATION: This project presents a patient centered curriculum for communication during critical aspects of patient care. For the work presented here, the evaluation will be the final coding scheme, which will then be refined based on iterative review by patients and clinicians.

DISCUSSION/REFLECTION/LESSONS LEARNED: In the next phase of the project, these emerging themes will be used to develop the content of an educational tool that combines patient and care-provider narratives with reflective exercises in order to enhance resident communication skills. The final phase of the project will include testing the tool for effectiveness. Utilizing patient and care provider experience as the foundation for curriculum development is a unique method for education in healthcare. With patient experience becoming rapidly more important for reimbursement, utilizing a patient centric approach to education specifically around communication is critical.

IMPACT OF A HOSPITAL MEDICINE ROTATION DURING INTERNAL MEDICINE RESIDENCY Luke Cunningham; Chirayu Shah; Erica Hubenthal; Doris Lin; Steffanie Campbell; Jeffrey T. Bates. Baylor College of Medicine, Houston, TX. (*Tracking ID #1937882*)

NEEDS AND OBJECTIVES: With the implementation of the ACGME duty hour restrictions for PGY1 residents in Internal Medicine, their exposure to inpatient medicine has declined. They are increasingly assuming care of patients admitted by other physicians rather than evaluating and developing management plans for new patients. Glasheen, et al. have also noted deficiencies in current Internal Medicine training for the growing role of hospitalists as they extend beyond traditional direct patient care. Non-clinical training needs include health-care economics, patient safety/quality improvement, continuums of care, leadership, and communication. Our objective was to create a new required PGY2 Internal Medicine rotation with a curriculum focused on skills needed for a physician primarily practicing inpatient medicine. The rotation would also provide increased inpatient experience with initial workup, assessment, management, and transitioning care of admitted patients. Program evaluation was done through pre- and post-rotation surveys. In addition, we also evaluated the curriculum delivery method.

SETTING AND PARTICIPANTS: The Resident Inpatient Training Experience (RITE) rotation is a one-month rotation at Baylor College of Medicine required for all PGY2 categorical Internal Medicine residents. Two PGY2 residents are assigned to each of the two hospital settings—Michael E. DeBakey VA Hospital and Ben Taub General Hospital. Over the course of an academic year, all 44 categorical PGY2 residents will rotate for at least 1 month on this rotation.

DESCRIPTION: An experienced hospitalist serves as the attending physician and works one-on-one with the residents without any students or interns. The RITE team admits an average of 16–18 patients from 7 am to 5 pm 4 days each week. There are no

overnight responsibilities. The residents attend one or two half-day continuity clinics each month to fulfill the requirements. The curriculum is provided to each resident in a workbook format divided into three modules: Basic Principles in Patient Safety and Quality Improvement, Advanced Quality Improvement and Cost Conscious Care, and Billing/Coding. Using principles from the flipped classroom model, the residents are expected to independently read the workbook and complete basic exercises. Each Monday morning, hospitalist faculty lead a facilitated exercise on applying the principles of the weekly module. Residents are asked to answer a pre-rotation and post-rotation survey.

EVALUATION: The pre-rotation survey ($n=20$, response rate 87 %) showed that residents identified deficits in their training in hospital reimbursement (85 %), hospital metrics (80 %), physician billing/coding (75 %), quality improvement (35 %), and patient safety (25 %). The post-rotation survey ($n=16$, response rate 84 %) showed 81.25 % strongly agreed and 18.75 % agreed that the rotation was important for training and education. The same number responded that the rotation would help their skills in leading a traditional ward team supervising interns and students. The residents' self-assessment of knowledge in the following categories increased: discharge planning/transitions of care (3.55 to 3.94), patient safety (3.6 to 3.86), quality improvement (3.45 to 3.56), cost conscious care (2.95 to 3.56), hospital reimbursement (2.5 to 2.94), physician billing/coding (2.2 to 2.88) [Likert scale 1 = very poor to 5 = excellent]. The interest to pursue a career in hospital medicine increased for 56.25 % of the residents on the RITE rotation. 62.5 % of residents preferred the independent workbook for curriculum delivery.

DISCUSSION/REFLECTION/LESSONS LEARNED: With a reduction in inpatient experience during intern year due to the ACGME duty hour restrictions, the addition of a required PGY2 hospitalist rotation during Internal Medicine residency helps to increase knowledge of many training needs identified for future hospitalists. The residents viewed the RITE rotation as important for their training and increased their confidence in leading a ward service. The rotation also led to more residents interested in pursuing hospital medicine as a career. Residency programs should consider alternative methods for curriculum delivery outside of the traditional didactics and Powerpoint slides. From this study, residents preferred using a workbook followed by a facilitated exercise.

IMPACT OF A TARGETED IPE CURRICULUM ON MEDICAL STUDENTS' PERFORMANCE; AN IPC OSCE CASE Jennifer Adams¹; Maja Djukic²; Marc Triola¹; Sondra Zabar¹; Adina Kalet¹; Linda Tewksbury¹; Jennifer Ogilvie¹; Sabrina W. Lee¹; Colleen Gillespie¹. ¹NYU School of Medicine, New York, NY; ²NYU School of Nursing, New York, NY. (*Tracking ID #1938507*)

NEEDS AND OBJECTIVES: Interprofessional collaboration (IPC) is increasingly recognized as fundamental to patient-centered medical care. Interprofessional education (IPE) has been associated with improved collaboration in practice and patient outcomes. Still, many medical schools have limited training in IPE. The NYUSOM and NYUCN, with support from the Josiah Macy Jr. Foundation, developed and implemented a comprehensive IPE curriculum for its students. The impact of this curriculum was evaluated by comparing performance in an IPC-focused OSCE (Objective Structured Clinical Examination) case between two medical school cohorts, the first naïve to the curriculum and the second who had completed the curriculum.

SETTING AND PARTICIPANTS: An IPE case was implemented as part of the end-of-third-year comprehensive clinical skills OSCE. The case prompted students to create an interprofessional care plan with a nurse for the patient they saw in a previous case, a 15-minute interview with a patient who came into urgent care with chief complaint of shortness of breath.

DESCRIPTION: Students were expected to use the SBAR (situation, background, assessment and recommendation) technique to communicate with the Standardized Nurse (SN) and to use CUS communication tool (I'm concerned; I'm uncomfortable; This is a matter of patient safety) if the nurse relayed any incorrect information. The SN was trained to make a specific mistake. A behaviorally anchored checklist was developed to assess IPC, including 4 items to assess use of SBAR, 1 item focused on using CUS to respond to the SN's information error, and 3 items focusing on core dimensions of collaborative practice (introducing professional role, collaborating in identifying next steps and implementing an interprofessional team care plan). Each of these used a 3-point response scale of "not done", "partly done", and "well done" and a composite score of % items rated by the SN as "well done" was calculated for each of the 3 IPC domains. Chi-square and t-tests were used to assess the significance of differences between frequencies and mean scores.

EVALUATION: 165 curriculum-naïve third year medical students completed the case and 123 post-curriculum third years completed the case the following year. The overall OSCE scores did not differ significantly between cohorts. The overall IPC

score did not differ significantly between cohorts (pre=21 % vs post=15 %; $p=.32$). In both cohorts, less than a third (28 % pre and 25 % post) of students collaborated with the nurse in developing a plan of action ($p=.59$). Significant differences ($p<.05$) were noted in the use of SBAR and CUS communication tools. Overall, mean SBAR and CUS scores for students completing the curriculum were significantly greater than students who did not ($p<.05$). Also, 72 % of pre-curricular students compared to 94 % of the post-curricular students used SBAR to present a patient-centered situational assessment ($p<.05$). Only half of the pre-curricular students used SBAR to comprehensively present the patient's background, while 81 % of the post-curricular students employed this tool ($p<.05$) and 41 % of the pre-curricular versus 53 % of the post-curricular students used SBAR to provide their assessment of the situation ($p<.05$). Only 27 % of the pre-curricular students used CUS in a skillful and respectful way in response to the nurse's error, while 40 % of the post-curricular students used this tool effectively ($p<.05$).

DISCUSSION/REFLECTION/LESSONS LEARNED: A targeted IPE curriculum effectively taught focused IPC skills (SBAR and CUS), but did not affect the overall ability for students to collaborate with a nurse and develop an IPC plan. This study illustrates that core skills can be taught and employed in a clinical setting and validates continued emphasis and dedicated curricular for IPC skills. However, full collaborative practice might require more experience in creating IPC care plans as well as continued exposure and education in this arena.

IMPLEMENTING A NOVEL MEDICAL STUDENT HEALTHCARE FOR THE HOMELESS CURRICULUM Andrew Coyle; Lauren Peccoraro. Icahn School of Medicine at Mount Sinai, New York, NY. (Tracking ID #1936375)

NEEDS AND OBJECTIVES: On any given night more than 50,000 individuals in New York City reside in shelters, an increase of nearly 70 % over the last 10 years. As nearly half of homeless individuals do not have health insurance, many do not receive regular medical care or receive care solely through shelter-based medical initiatives. Complex psychosocial circumstances affect health at all levels, limiting access and interrupting continuity, and often results in poor overall health. The expansion of Medicaid through the Affordable Care Act should improve homeless individuals' access to the broader healthcare system, resulting in increased exposure for trainees. However, medical students at the Icahn School of Medicine at Mount Sinai (ISMMS) have no formalized training in or exposure to issues in homeless health. The objectives of this curriculum are to explore the social and psychological implications of homelessness on health, to discuss available resources for homeless persons and how to facilitate access, and to educate trainees on appropriate treatment strategies for high-prevalence conditions. Finally, the curriculum will enhance and standardize the clinical experience through case-based learning.

SETTING AND PARTICIPANTS: Third year medical students at ISMMS spend 1 month on an ambulatory clerkship. All students participate in the didactic portion of the curriculum while 25 % of students rotate through clinical sites in city homeless shelters that provide both routine and urgent care. The shelter clinics have private examination rooms and are staffed with a social worker, registered nurse, and attending physician.

DESCRIPTION: The central component of the curriculum is a didactic session given to all students. The objective of the first half of the session is to review the characteristics/demographics of the homeless population, implications of homelessness on health, available resources for homeless persons, and the reasons for the significant rise in homelessness. The objective of the second half is to discuss population-specific screening and treatment strategies for common conditions in the homeless population (including diabetes/hypertension, HIV, Hepatitis C, and TB) via interactive cases. Students work through short cases as a group and discuss challenges of caring for homeless persons, such as selecting low-cost medications, optimizing medication adherence in patients with complex social issues, and arranging preventive care. This session has been piloted with approximately 50 medical students this academic year. In addition to the didactic sessions, the curriculum will enhance and standardize the clinical experience for those students who rotate through the shelter clinics. Working with clinic preceptors, a list of frequently encountered conditions and clinical scenarios will be generated to create a database of case-based handouts. In conjunction with patient encounters, these will facilitate more robust preceptor-student discussion about medicine in the shelter setting. For example, a handout on breast cancer screening might include current USPSTF and ACS recommendations and data on national and homeless-specific screening rates. This handout could then be used by the preceptor, in the setting of seeing a patient due for mammography, to discuss challenges of completing preventive care in the homeless population.

EVALUATION: Students will complete a pre- and post-curriculum survey. The pre-test (needs assessment) will gauge baseline levels of knowledge, as well as prior experiences and comfort level with the homeless population. Students will also take the Attitudes Toward Homelessness Inventory (ATHI), a validated tool. After the curriculum, students will take a post-test and retake the ATHI to assess for knowledge or attitudinal changes.

DISCUSSION/REFLECTION/LESSONS LEARNED: Homeless individuals represent a growing and complex population in health care, and it is important that practitioners be well-versed with the challenges to providing high-quality care. Significant variability in student knowledge has been noted in current teaching sessions where students have voiced numerous common misconceptions about the homeless population (for example, that the street homeless are representative of the overall population, when in fact they represent less than 10 % of the overall population). This demonstrates that significant educational work is needed. Early formative feedback from students about the didactic pilot has been positive and has highlighted the unique nature of the curriculum. This curriculum gives students a base of knowledge about homeless healthcare through didactics and case-based discussion, and, in conjunction with direct patient encounters for those who rotate at the clinical sites, will provide necessary exposure to the unique social and medical characteristics of the homeless population.

IMPLEMENTING CHANGE IN CLINICAL PRACTICE CULTURE: PAIN AND OPIOID MANAGEMENT BOOTCAMPS FOR VA CLINICIANS Karen H. Seal^{2,1}; Emily Sachs¹; Tracy Lin¹; Gary Tarasovsky¹; Daniel Bertenthal¹; Christopher J. Koenig^{2,1}. ¹SFVAMC, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA. (Tracking ID #1931958)

NEEDS AND OBJECTIVES: Primary care providers (PCPs) prescribe opioids for chronic non-cancer pain, despite a lack of evidence for their use. In turn, some patients, particularly those with comorbid mental health conditions, use opioids in excess to self-medicate psychosocial distress, sometimes with lethal consequences. Current clinical practice guidelines (CPGs) emphasize the biopsychosocial model of chronic pain self-management, yet CPGs are rarely used, and PCPs are not comfortable counseling patients about safer opioid use and non-opioid, non-pharmacological strategies for pain self-management. This interactive training aimed to educate providers about: (1) safer opioid prescribing and pain self-management, and (2) how to communicate more effectively with challenging chronic pain patients.

SETTING AND PARTICIPANTS: For this implementation project, we partnered with leadership at the San Francisco VA Medical Center (SFVAMC) to develop a 90-minute "Pain and Opioid Management Bootcamp" with an accompanying formative evaluation. Three opioid bootcamp trainings have taken place, two of which were broadcast by V-TEL (video telehealth) to 6 affiliated VA CBOCs throughout Northern California. To date, 140 clinical staff members have participated in the bootcamp and 125 (89 %) have completed pre- and post-training evaluations.

DESCRIPTION: In this interactive training, learners "assist" a PCP in a dramatized clinical scenario to make several clinical decisions about pain management. Using lessons from the training, learners manage a new complex chronic pain patient with comorbid mental health problems, including a history of heavy drinking, who is inappropriately prescribed benzodiazepines for posttraumatic stress disorder. In this scenario, the patient requests the same high-dose opioid regimen he received from a previous provider. The training reviews data on the questionable benefits and known harms of chronic opioid therapy including overdose, endocrine disruption, sleep disturbance, etc.... Throughout the training, the PCP models the use of Universal Precautions for opioid prescribing including: (1) Assessment of pain and risk for opioid misuse (using standard screens); (2) Consideration of non-opioid and non-pharmacological adjuncts and alternatives; (3) Shared decision-making in developing an Opioid Pain Care Agreement; and (4) Monitoring and re-adjustment (if the opioid trial fails, e.g., necessitating taper). The PCP models the use of the "VEMA" (validation, education, motivation, and activation) communication framework to implement Universal Precautions while maintaining a therapeutic relationship to reduce patient harms.

EVALUATION: Mixed methods were used to evaluate the training. T-tests were used to evaluate changes before and after the training using scaled and multiple choice items, and qualitative methods were used to describe open-ended feedback. To date, there have been significant improvements in knowledge and perceived comfort regarding safe opioid prescribing and chronic pain management (all p-values <0.001). Learners were confident that they would apply lessons learned to their clinical practices (scale of 0 to 4, mean score=3.34, SE=0.07).

DISCUSSION/REFLECTION/LESSONS LEARNED: With stakeholder support, brief trainings can be implemented in clinical practice groups to successfully educate clinicians about safer opioid prescribing, which can begin to shift the practice culture toward a biopsychosocial model for chronic pain self-management. This training has been archived as a training DVD and is being adapted as a web-based training for dissemination. Future evaluations will investigate changes in clinical practice behavior.

IMPROVING APPROPRIATE PPI THERAPY INITIATION AND POST-DISCHARGE PRESCRIPTIONS; HOUSE STAFF EDUCATION PROJECT AND COST-SAVING ANALYSIS AMONG VA MEDICINE INPATIENTS **Talia S. Gracer¹; Victor Moles^{2,1}; Cherinne Arundel².** ¹Medstar Georgetown University Hospital, Washington, DC; ²Washington, D.C. Veterans Affairs Medical Center, Washington, DC. (*Tracking ID #1934729*)

NEEDS AND OBJECTIVES: Proton pump inhibitors (PPIs) were first marketed in the late 1980s, and since that time PPI use has skyrocketed, now ranking second in pharmaceutical expenditure worldwide, estimated at \$11 billion annually in the US alone. This substantial cost prompted evidence-based strategies for PPI use, including the American Society of Health-System Pharmacologists (ASHP) Therapeutic Guidelines on Stress Ulcer Prophylaxis (SUP). These indications for SUP are limited to ICU patients, yet inappropriate prescribing of PPIs for the purpose of SUP in low-risk patients is a national problem that is costly and potentially harmful to patients. Prior literature proved significant improvements in appropriate PPI prescribing after one-time educational interventions by pharmacists and physicians. The culture of inappropriate PPI prescribing is evident in our institution. We feel it can be changed through education of Medicine trainees, as they are very often the frontline for prescribing medications in academic institutions. Our proposed objective is to use an ongoing educational program to decrease unwarranted inpatient PPI prescriptions, and in turn decrease inappropriate continuation of PPI prescriptions after discharge, thereby decreasing both the total cost of inpatient hospitalizations and the secondary risk factors associated with PPI usage among VA patients. This research should extend improved outcomes through repeated educational sessions and emphasis on medicine reconciliation, potential side effects, and cost.

SETTING AND PARTICIPANTS: All Medicine admissions to the Washington, D.C. VAMC between September 2012 and February 2013 who received a PPI, were randomized for retrospective chart review for pre-intervention data. The Internal Medicine residents, medical students, and attendings rotating monthly through the Washington, D.C. VA Medical Center (VAMC) general medicine wards, between September 2013 and February 2014, receive the educational intervention. Admission data from this time period will be analyzed for post-intervention retrospective analysis.

DESCRIPTION: The educational intervention includes the definition of "stress ulcer prophylaxis," stress ulcer pathophysiology, ASHP-approved indications for PPIs, outpatient indications for PPIs, PPI side effects and drug interactions, ways to decrease inappropriate prescribing, including admission and discharge medicine reconciliation, and discontinuation of inpatient PPIs once risk factors resolve. All participants receive an index pocket-card with this information.

EVALUATION: Completed a retrospective chart review of 185 pre-intervention patients who received PPIs during their admission to the Washington, D.C. VAMC between September 2012 and February 2013. Charts were evaluated for PPI appropriateness criteria based on the ASHP guidelines and the 2010 Pharmacist Letter guidelines. Pre-intervention data results include: 69 % of patients were already on PPI at time of admission and 40 % of these PPIs continued without indication. Sixty percent of all PPIs prescribed at the time of admission lacked a documented indication, and 33 % of these prescriptions were continued on discharge. Our plan is to continue with monthly intervention of house staff teaching until February 2014 and use T-tests compare pre- and post-intervention data, and cost analysis.

DISCUSSION/REFLECTION/LESSONS LEARNED: Unfounded cultural habits within medicine, including defensive medicine, can have a negative impact on cost and patient care. Targeted educational initiatives and physician awareness can greatly improve outcomes and lower health care costs. By reducing the number of inappropriate PPI prescriptions we expect to lower costs in medication prescriptions and potentially decrease side effects (C. difficile infections, pneumonia) and medication interactions. Future directions of our project consist in incorporating teaching into a year-long monthly curriculum, and include electronic prompts in the electronic medical record when prescribing PPIs to improve compliance. Due to the unexpectedly high rate of outpatient PPI prescriptions, we plan to extend the teaching sessions to the outpatient VA physicians. Will complete a cost analysis with post-intervention data to evaluate VAMC and patient cost reduction.

ONLINE RESOURCE URL (OPTIONAL): ASHP Therapeutic Guidelines on Stress Ulcer Prophylaxis. <http://www.ncbi.nlm.nih.gov/pubmed/10690219> PHARMACIST'S LETTER/PRESCRIBER'S LETTER July 2010, Volume 26, Number 260705. <http://pharmacistsletter.therapeuticresearch.com/pl/detaildocuments/270401-3206.pdf?cs=&s=PL>

IMPROVING HOUSE STAFF CONTINUITY ON INPATIENT CARDIOLOGY SERVICES INCREASES PHYSICIAN AND NURSING PERCEIVED QUALITY OF CARE **Melissa Dattalo^{1,2}; Ryan E. Childers^{1,3}; Colleen Christmas¹.** ¹Johns Hopkins Bayview Medical Center, Baltimore, MD; ²University of Wisconsin, Madison, WI; ³Oregon Health & Science University, Portland, OR. (*Tracking ID #1939061*)

NEEDS AND OBJECTIVES: Many medical educators believe that the 2011 Accreditation Council for Graduate Medical Education (ACGME) duty hour restrictions fragment the continuity afforded by traditional overnight call schedules and subsequently reduce quality of care. We restructured our institution's house staff rotations in the cardiology intensive care unit (CICU) and cardiology progressive care unit (PCU) with two simultaneous objectives: 1) Maximize daily continuity between house officers and cardiology patients, and 2) Comply with ACGME duty hour regulations.

SETTING AND PARTICIPANTS: House officers were surveyed ($n=17$) about their experiences on the cardiology rotation at Johns Hopkins Bayview Medical Center (originally a combined CICU and PCU experience) at baseline in July 2012. A newly structured rotation involving separate teams working in the CICU or PCU was piloted from August 2012–January 2013. A follow-up survey about the pilot rotation experience was administered to house officers ($n=25$), cardiology nursing staff ($n=19$), and cardiology faculty ($n=7$) in January 2013.

DESCRIPTION: At baseline, two cardiology house staff teams of 4 house officers plus a cardiology float resident and a physician assistant (PA) were responsible for all cardiology patients in the CICU and PCU. The pilot intervention assigned 6 house officers dedicated to CICU patients, assigned 3 house officers dedicated to PCU patients, and eliminated the need for house staff "cross-coverage" of PA patients overnight. The total number of cardiology house officers and the total number of cardiology beds did not change.

EVALUATION: On a scale from -5 (worst) to +5 (best), the pilot intervention improved house officer-perceived impact of patient continuity on quality of care from -2.9 to 3.1 ($p=0.00$) for CICU interns, from -0.4 to 2.0 ($p=0.01$) for CICU residents, from -1.6 to 2.6 ($p=0.00$) for PCU interns, and from -0.04 to 2.1 ($p=0.00$) for PCU residents. Seventy-three percent of house officers, 75 % of PCU nurses, and 60 % of faculty surveyed reported the intervention improved quality of patient care in the PCU. Sixty-seven percent of house officers, 80 % of CICU nurses, and 67 % of faculty surveyed reported the intervention improved quality patient care in the CICU. Eighty-one percent of house officers, 85 % of PCU nurses, and 80 % of CICU nurses stated the intervention enhanced interdisciplinary teamwork. The 30 day readmission rate in the PCU decreased from 18.41 % at baseline to 16.38 % during the intervention period. Average length of stay in the PCU decreased from 5.59 days at baseline to 5.05 days during the pilot intervention and readmission length of stay decreased from 6.50 days to 5.35 days.

DISCUSSION/REFLECTION/LESSONS LEARNED: The new 2011 ACGME duty hour regulations offered our institution an opportunity to restructure the house staff cardiology rotation to increase continuity of care between house officers and patients. Changes aimed at maximizing continuity of care also improved interdisciplinary teamwork, discharge planning, and overall quality of patient care as perceived by house staff, nurses, and faculty.

INNOVATIVE INTERPROFESSIONAL GERIATRIC EDUCATION FOR MEDICAL AND NURSING STUDENTS: FOCUS ON TRANSITIONS IN CARE **Seki A. Balogun¹; Karen Rose²; Shannon Thomas².** ¹University of Virginia Health System, Charlottesville, VA; ²University of Virginia Health System, Charlottesville, VA. (*Tracking ID #1927010*)

NEEDS AND OBJECTIVES: Interprofessional education (IPE) is increasingly essential for all health care professions and is crucial in fostering effective team based patient care, which in turn improves the quality of care and patient outcomes (1). This is especially important in caring for older adults whose needs are often not recognized or met in very complex healthcare delivery systems and are particularly vulnerable to adverse effects across the continuum of care (2). Transitioning care of the elderly, especially those with cognitive or functional deficits, is a very complex process, involving several disciplines and requires careful coordination of care. Inappropriate transition of geriatric care can lead to increased hospital readmissions and adverse

drug effects including medication errors, all of which adversely affect patient outcomes. In addition, it leads to increased cost of health care through duplication of services (3–5). Several studies show that comprehensive interdisciplinary assessments can greatly improve outcomes in transitions of geriatric care (6,7). Utilizing IPE experiences in training health care professionals can foster effective collaboration across these professions and greatly improve transitions of care in the elderly. As part of the University of Virginia Health System's initiative on IPE, we developed and implemented an interprofessional geriatric education workshop for nursing and medical students with a focus on transitions in geriatric care.

SETTING AND PARTICIPANTS: A total of 192 students (107 medical students and 85 nursing students) participated in a 90-minute, interactive, case-based workshop.

DESCRIPTION: The monthly workshops were conducted with groups of an average of 12 medical and 9 nursing students over 1 year. These were facilitated by nursing and medical faculty. Self-perceived competencies in necessary IPE skills and attitudes toward interprofessional teamwork were measured through surveys. Data were analyzed using descriptive and nonparametric statistics.

EVALUATION: Over 90 % of students were better able to describe the necessary interprofessional communication needed to develop a patient-centered care plan in transitioning patients between clinical sites. Four out of five students reported an enhanced appreciation of interprofessional teamwork and stated that the learning experience was valuable. They were also able to identify legal, financial and social implications in transitions of care (77 %). Interestingly, nursing students consistently rated the workshop more highly than medical students across most domains ($P<.05$).

DISCUSSION/REFLECTION/LESSONS LEARNED: Students improved and demonstrated their knowledge of interprofessional communications skills and strategies required in transitions of geriatric care. Their teamwork skills were also enhanced. Introducing these concepts in medical and nursing training fosters effective interprofessional communication and collaboration. References 1. INTERDISCIPLINARY EVIDENCE-BASED MEDICINE COURSE DESIGN FOR NAS MILESTONE ASSESSMENT THROUGH ONLINE ADAPTIVE LEARNING STRATEGIES Ravi Gupta¹; Kell Julliard²; Juan Barrientos². ¹Lutheran Medical Center, Brooklyn, NY; ²Lutheran Medical Center, Brooklyn, NY. (Tracking ID #1940936)

NEEDS AND OBJECTIVES: ACGME's Next Accreditation System (NAS) measures competency in essential tasks of clinical practice, including the ability to find and evaluate clinical research to improve care. Journal Clubs are our primary teaching venue for evidence-based medicine (EBM), but we were unable to fully assess all participants' understanding of the concepts presented. Moreover, residents leading journal clubs had variable prior knowledge of EBM, resulting in similarly variable learning experiences for the audience. On the wards, attending physicians evaluated residents' integration of EBM with clinical care as opportunities arose, leading to inconsistent assessment. The Association of Professors of Medicine reported that although 59 % of online courses reviewed had some type of assessment, none monitored resident learning or objectively reported on milestones (2012). The study called for development of e-Learning courses perceived by students as "providing an advantage over traditional curriculum." Thus, our specific project goals were to: • Develop clear EBM learning objectives related to milestones and national guidelines • Bring teaching of EBM in line with recent developments in learning theory • Take advantage of new learning technologies • Enhance resident learning and clinical application of EBM The project team reflected the three essential

areas of expertise: a physician provided clinical relevance and accuracy; an EBM expert led content development; and an instructional designer created a pedagogically sound course design informed by learning theory.

SETTING AND PARTICIPANTS: Internal Medicine residents and faculty at an inner city community teaching hospital

DESCRIPTION: The EBM Curriculum comprises the following modules: Introduction to EBM, Randomized Controlled Trials, Cohort and Case-control Studies, Diagnostic Tests, and Meta-Analyses. The course is SCORM compliant and adaptable to any Learning Management System. Modules are optimized for mobile platforms on Android and iOS. Modules cover the basic principles of each EBM study type and integration of research findings with clinical care through the use of four primary modalities: video, animation, simulation, and text. The curriculum emphasizes user-driven adaptability of course content (adaptive learning): the sequence of the course is dependent on user responses to continuous, embedded assessment. Users are remediated only as necessary. Data document each user's proficiency. Two modules are complete: Introduction to EBM and Randomized Controlled Trials. The third will be complete by the date of the conference. Each assessment item is mapped to specific curricular NAS milestones. User responses including applicable milestone, correctness of responses, number of attempts, and need for remediation are routed to departments for reporting to ACGME.

EVALUATION: 97 % of residents were either satisfied or very satisfied with the course. Ninety-seven percent believed that the modules would improve their clinical skills and practice.

DISCUSSION/REFLECTION/LESSONS LEARNED: Residents participated willingly in taking the modules, and the great majority perceived them as directly benefiting clinical practice. In module testing, residents' individual learning preferences became apparent, which will guide development of future modules. Making explicit the evidence grading system for online EBM repositories was perceived by residents and faculty as having great clinical relevance. Significantly more time was needed to develop modules than originally anticipated.

ONLINE RESOURCE URL (OPTIONAL): Two modules are available for review at <http://lmcmc.certpointsystems.com>. Login names are SGIM1, SGIM2, SGIM3, SGIM4, SGIM5; password is password.

INTERNAL MEDICINE RESIDENTS' ATTITUDES AND BELIEFS OF ACHIEVING THEIR CLINICAL COMPETENCY MILESTONES DURING THEIR NIGHT FLOAT ROTATION Brian E. Foster; Maryann T. Ally. Walter Reed National Military Medical Center, Bethesda, MD. (Tracking ID #1937176)

NEEDS AND OBJECTIVES: We created standardized presentations for the internal medicine residents on their two-week night float rotation, but it is not known how this impacts their learning experience. At our medical center, most attending physicians supervise cross-cover issues of night float residents during one 2-week period per academic year, leading to a varied learning experience. Our PowerPoint presentations encompass common, cross-cover issues, including atrial fibrillation with rapid ventricular response, bowel management, chest pain, delirium, hypotension, hypertension, mechanical falls, neutropenic fever, pain management, post-operative complications, and stroke. The presentations were disseminated on our password-protected internal medicine website for easy access. The resident on the night float team was instructed to lead a discussion with the interns using these presentations. We developed a survey to assess internal medicine residents' attitudes and beliefs of achieving their clinical competency milestones after the implementation of these standardized presentations.

SETTING AND PARTICIPANTS: Internal medicine residents in a single-site, academic medical center.

DESCRIPTION: A voluntary and anonymous 9-question survey was distributed electronically to our internal medicine residents during a two-week period in December 2013.

EVALUATION: Of the total 70 internal medicine residents, 23 residents responded to the survey, including 10 PGY-1, 9 PGY-2, and 4 PGY-3. Of the survey respondents, 12 had completed the night float rotation, and 11 had used the night float standardized presentations as outlined above. 84.6 % had used between 1 and 3 lectures on average per week while 15.4 % used an average of 4–6 lectures per week. The majority (77 %) spent an average of 5–15 min per presentation. 45.5 % felt the presentations allowed them to become better teachers, 18.2 % referred to the presentations during the night float rotation when encountering a clinical problem, and 9.1 % referred to the presentations after the night float rotation was completed when encountering a

clinical problem. Over half (54.5 %) felt the night float presentations improved their overall clinical knowledge and 1 respondent (9.1 %) stated the presentations improved development of a comprehensive management plan. 27.3 % noted improvement in their effective communication of diagnostic and treatment plans to patients and caregivers after utilizing these presentations. One respondent (9.1 %) felt clinical questions to consultants were better framed as a result of these presentations.

DISCUSSION/REFLECTION/LESSONS LEARNED: Using a brief survey, we assessed the attitudes and beliefs of our internal medicine residents regarding their clinical competency milestones during their night float rotation. In developing and implementing standardized presentations on commonly encountered cross-cover issues, we aimed to enhance the learning experience of our residents and to encourage our residents to become better teachers, communicators, and, ultimately, independent practitioners. This survey identified areas of resident improvement, including developing more comprehensive management plans and communicating more clearly with patients and consultants. We will address these needs by strengthening our curriculum and developing more quality improvement initiatives with our residents.

LONGITUDINAL PATIENT SATISFACTION DATA AFTER INSTITUTING A 4+2 PRACTICE MODEL IN RESIDENT CONTINUITY CLINIC Julie Oyler; Lisa M. Vinci; Wei Wei Lee; Eileen Wang; Vineet Arora. University of Chicago, Chicago, IL. (*Tracking ID #1938913*)

NEEDS AND OBJECTIVES: Many internal medicine programs have recently instituted a block scheduling model such as the 4+2 model for ambulatory training. As opposed to traditional training models where residents leave inpatient responsibilities for one half day a week to take care of continuity clinic patients, the 4+2 model of training separates inpatient and outpatient responsibilities. Little research has been done on the impact of this training model on patient satisfaction.

SETTING AND PARTICIPANTS: On July 1, 2013, an academic internal medicine training program transitioned to a 4+2 model in which residents spend 4 weeks on inpatient rotations followed by 2 weeks of outpatient clinic. During the 2 weeks on outpatient, residents participate in 8 half day continuity clinics, 4–6 half day subspecialty clinics, 4 half day teaching sessions and 2–4 administrative sessions per 2 week block. During the 4 weeks on inpatient, residents' continuity clinic patients are covered by another resident.

DESCRIPTION: Since 2010, American Board of Internal Medicine (ABIM) Cancer Screening Practice Improvement Module (PIM) paper surveys have been administered annually from July to November to patients in the resident continuity clinic. PGY2 residents hand anonymous paper surveys to patients, these surveys are then entered into the ABIM PIM website by staff. This annual patient survey data was used to evaluate patient demographics, satisfaction and access to the resident practice before and after the 4+2 curricular change.

EVALUATION: From 2010 to 2012 (pre data) 273 patient surveys and in 2013 (post data) 90 were completed. The majority of patients were female (pre 188/273, 68 %, post 68/90, 76 %) and over the age of 50 (pre 209/273, 76 %, post 76/90, 84 %). About one third of patients rated their health "fair to poor" (pre 88/273, 32 %, post 30/90, 33 %) and another third rated their health "very good to excellent" (pre 64/273, 23 %, post 31/90, 34 %). Patients responded that "the practice was excellent at encouraging question and answering them clearly" (pre 144/273, 53 %, post 51/90, 57 %) and that they would "recommend this practice to others" (pre 253/273, 93 %, post 80/90, 89 %). When evaluating access to the resident practice, patients reported no problems with scheduling appointments (pre 167/269, 62 %, post 65/90, 72 %), reaching someone with a question (pre 175/262, 67 %, post 66/88, 75 %), obtaining prescription refills (pre 196/258, 76 %, post 60/87, 69 %), obtaining test results (pre 212/258, 82 %, post 75/84, 89 %), and obtaining referrals (pre 191/241, 79 %, post 65/84, 77 %).

DISCUSSION/REFLECTION/LESSONS LEARNED: The 4+2 schedule more closely matches the responsibilities of a general internist. However, there are periods of 4–8 weeks at a time when the resident is not available and covered by a fellow resident. Interestingly, patients were more satisfied with scheduling appointments but less satisfied with obtaining prescription refills. Despite this curricular change there was no significant change in most areas of patient satisfaction or access to the resident practice.

LONGITUDINAL RESIDENT-STUDENT PATIENT CARE COLLABORATION IN PRIMARY CARE Amy Pasternack^{1,2}; Katherine Lupton^{1,2}. ¹Cambridge Health Alliance, Cambridge, MA; ²Harvard Medical School, Boston, MA. (*Tracking ID #1939424*)

NEEDS AND OBJECTIVES: Although the majority of patient care in internal medicine occurs in the ambulatory domain, the bulk of residency training has traditionally taken place in the inpatient setting. Consistent with this, residents receive little exposure to and training in teaching medical students outpatient medicine. Our near-peer educational exchange between PGY-2 and -3 residents and third year medical students will build residents' skills in outpatient teaching, improve continuity of care for complex patients, and increase the number of complex adult primary care patients that medical students follow longitudinally.

SETTING AND PARTICIPANTS: Cambridge Health Alliance (CHA) is well known for pioneering a longitudinal integrated clerkship for third year Harvard medical students, the Cambridge Integrated Clerkship (CIC). Most of the student teaching in this program is done by attending physicians in the ambulatory setting; as a result, CHA internal medicine residents have fewer opportunities to teach medical students than do residents at many other medicine training programs. The CHA internal medicine residency follows a 2+4 immersion model in which two-week ambulatory blocks with concentrated time in primary care clinic alternate with four-week inpatient or elective rotations when residents are out of continuity clinic entirely; during inpatient blocks it can be challenging for residents to maintain close follow up with their more complex patients. This project is being piloted at the Windsor Street Health Center, a safety-net community health center that is the ambulatory medicine training site for six internal medicine residents and four CIC students.

DESCRIPTION: We are currently piloting a collaborative patient care experience in which CIC students pair with PGY-2 and -3 primary care providers to longitudinally co-follow complex medical patients. The student and resident see their collaborative patients together: the student is primarily responsible for running the patient visits while the resident directly observes and helps guide the encounter. The student then presents to the resident—who acts as preceptor for the visit—in the presence of an experienced faculty preceptor who ensures the quality of patient care while observing and later providing feedback on the resident's teaching skills. The students follow their collaborative patients over the course of the clerkship year, benefiting from frequent direct observation and feedback while learning principles of ambulatory medicine and serving as a point of continuity with patients while residents are out of clinic. The residents, who also complete an ambulatory resident-as-teacher curriculum, gain mentored experience teaching students outpatient medicine. Further work is needed to build the resident-as-teacher curriculum, generate guidelines for patient selection, and establish administrative processes to facilitate the complex schedules involved.

EVALUATION: We are in the early stages of piloting this project. An initial pilot by one resident and two medical students has shown the project to be feasible within the resident and medical student clinic schedules, and other residents and medical students have expressed interest in participating. Residents and students will complete mid-year and year-end surveys assessing their comfort with ambulatory teaching and primary care medicine, respectively, and residents' teaching skills will be periodically assessed by students and faculty.

DISCUSSION/REFLECTION/LESSONS LEARNED: This program increases residents' exposure to medical student teaching in a supervised environment in which they can explore outpatient teaching styles and techniques while receiving feedback and mentoring from experienced educators. Prior to this, ambulatory resident-as-teacher experiences in this residency were limited to resident-run peer didactics. Students benefit from near-peer teaching and direct observation, and are empowered by the opportunity to be an integral member of the healthcare team and serve a key role in maintaining patient continuity over the course of the clerkship year. Defining appropriate patients—who are medically and psychosocially complex enough to require frequent clinic visits and would benefit from continuity with a medical student, but not so complex that the student is overwhelmed and unable to run the visits—has proven to be an early challenge and is a main focus of program development for the remainder of the pilot year.

MEDICAL STUDENTS AS PRIMARY CARE PROVIDERS: AN INTEGRATED MEDICAL STUDENT CLINIC THAT OFFERS A TRUE LONGITUDINAL PRIMARY CARE EXPERIENCE Serene I. Chen; Rebecca Liu; Pinar Oray-Schrom. Yale School of Medicine, New Haven, CT. (*Tracking ID #1925854*)

NEEDS AND OBJECTIVES: Longitudinal clinical care experience is a rarely-met need in medical school education. The Wednesday Evening Clinic (WEC) at the Yale New Haven Hospital adult Primary Care Center (PCC) is a student clinic founded to

address this need. It aims to: 1. Provide Yale medical students opportunity for a longitudinal clinical outpatient experience. 2. Offer students the opportunity to care for their own patient cohort and function as primary care providers (PCPs). 3. Provide outstanding medical care for an underserved patient population.

SETTING AND PARTICIPANTS: The WEC is a weekly student-staffed clinic, fully-integrated into the adult PCC of Yale-New Haven Hospital. Annually, 15 medical students beyond their 3rd year participate for at least 1 year.

DESCRIPTION: The WEC was founded in response to medical students' desire for a longitudinal clinical experience. Modeled after group practice, students are divided into patient care teams, each supervised by a designated faculty attending and rotating volunteer attendings from the Yale and New Haven medical communities. As PCPs, students perform general health maintenance, chronic disease management, age-appropriate screening, counseling and patient-care coordination. Follow-up extends beyond clinic hours. Weekly attendance over 1 year, in conjunction with regular evaluations by faculty, satisfies the primary care clerkship requirement. The WEC is supported jointly by Yale-New Haven Hospital and Yale School of Medicine.

EVALUATION: We surveyed WEC students from 2008 to 2013 on their experience. Throughout this time, over 60 medical students have served as PCPs. Survey results indicate that the WEC provides a unique longitudinal clinical experience not found in the traditional medical school curriculum. Students unanimously report increased comfort in providing ambulatory care after participating in the WEC. In addition, 38 % of WEC graduates pursued residency in primary care specialties versus 33 % among non-WEC graduates. We surveyed patients on their clinic perception and satisfaction. Results indicate that patient flow and wait time are areas for improvement. Prolonged visits and delays are likely due to the requirement for close supervision by attendings.

DISCUSSION/REFLECTION/LESSONS LEARNED: Unlike other free or urgent care student clinics, the WEC is fully integrated into a well-established PCC of a teaching hospital, enabling students to follow results and care over time. The WEC is a unique experience in terms of degree of responsibility, ownership, and longitudinal exposure to patient care, with students functioning as PCPs. It provides insights into disease courses and opportunities for building patient-provider relationships, which are of increasing importance given the rising demand for primary care. The WEC fulfills primary care clerkship requirements, an additional innovation that builds structure for regular feedback and evaluation. The WEC is possible and sustainable by support from Yale School of Medicine, Yale-New Haven Hospital and dedicated volunteer attendings. Billing from encounters contributes to covering facility and staff costs. However, the long-term financial sustainability of the clinic depends on the overall financial health of the Yale-New Haven Health System. While similar opportunities are presently rare, this model can be scaled and implemented elsewhere, especially in light of increasing demand for primary care training.

MOBILE DEVICE APPLICATION BASED EDUCATIONAL TOOL TO IMPROVE COST-CONSCIOUS CARE AMONG INTERNAL MEDICINE RESIDENTS Auras R. Atreya¹; Behdad Besharatian¹; Stefano Bucy²; Thomas Higgins^{1,3}. ¹Baystate Medical Center/Tufts University School of Medicine, Springfield, MA; ²University of Massachusetts, Amherst, MA; ³Baystate Medical Center/Tufts University School of Medicine, Springfield, MA. (*Tracking ID #1939067*)

NEEDS AND OBJECTIVES: Cost of care in the United States is substantially higher than other nations and health care over-utilization is an area of focus in today's economic environment. The American Board of Internal Medicine Foundation recently launched the 'Choosing Wisely' initiative, aimed at reducing overuse of tests and procedures. Of the major drivers of overuse, one of the proposed physician-related factors is physician culture, which emphasizes thoroughness during medical education and training years. It is possible that this leads to increased test ordering in order to obtain an exhaustive evaluation. However, it has been previously shown that medical residents have poor knowledge of the cost of diagnostic tests. Given that cost-effective care is part of the competencies required by the Accreditation Council for Graduate Medical Education (ACGME), there exists an opportunity to improve awareness of diagnostic tests and facilitate cost-effective care. Our objective was to develop an educational intervention that would raise awareness of medical residents with regard to frequently ordered diagnostic tests.

SETTING AND PARTICIPANTS: Baystate Medical Center is an academic medical center in Springfield, MA that serves as the Western Campus of Tufts University School of Medicine. Educational curriculum for internal medicine residents and

medicine-pediatrics residents on the inpatient medicine service includes a half-hour morning report that is based on clinical case-based learning. This is an interactive session where residents hone critical decision-making and are involved in determining appropriate work-up for each particular presentation.

DESCRIPTION: We developed an android OS based application for mobile devices that would display the cost of commonly ordered tests. Cost of tests was based on fee-schedule that was obtained from the Financial Department at Baystate Medical Center. The mobile device can be connected to a projector and the cost of the last ordered test is displayed along with total cost of tests ordered in real-time during morning report. Tests included in the application comprise of serum chemistries, hematological tests, cardiac enzymes, CSF, urine and stool studies. Frequently ordered radiological tests, echocardiography and stress tests were also built into the application.

EVALUATION: Prior to implementing this application in morning report sessions, we conducted a pre-intervention survey where we asked all residents present at an academic half day (protected time to ensure attendance of all internal medicine and medicine-pediatrics residents) to estimate the value of 10 commonly ordered diagnostic tests. We will then educate residents to use the application during morning report. Since only the residents on inpatient medicine service attend morning report, we will have a group of residents exposed to the application in addition to those not exposed to the application. This will then allow us to conduct a post-intervention survey to compare the effect of the educational intervention in those exposed to the application, with the unexposed group serving as a control group.

DISCUSSION/REFLECTION/LESSONS LEARNED: Although educational interventions to encourage cost-effective care among resident physicians have been developed before, this Android application is an innovative tool aimed at incorporating cost-consciousness into the initial work-up of patients admitted to the hospital without compromising thorough medical evaluation. Utilizing this tool during morning report will remain feasible since it does not involve a major change from current practices and it can become part of curriculum for residents on inpatient medicine service. Ultimately, the goal is to extend the use of this application in routine day-to-day patient care on the medicine wards and continue to teach cost-containment to medicine and medicine-pediatrics residents.

MOBILE-CENTERED SPACED LEARNING: A NOVEL APPROACH TO GRADUATE MEDICAL EDUCATION IN THE DIGITAL ERA Robert J. Walter; Anantha K. Mallia; Ali Massoumi; Joshua Hartzell. Walter Reed National Military Medical Center, Bethesda, MD. (*Tracking ID #1938605*)

NEEDS AND OBJECTIVES: Developing an optimal learning environment and curriculum in graduate medical education can be challenging, particularly in light of progressive work hour restrictions limiting the feasibility of traditional academic didactics that compete with patient care duties. Emerging literature has demonstrated the effectiveness of "spaced learning" within medical education as a viable adjunct to conventional pedagogy. This method of learning has been found to improve knowledge acquisition, increase long-term knowledge retention, and improve a learner's ability to accurately self-assess their knowledge. However, spaced learning shares the same limitations as many other learning models with regard to accessibility, ease of use, and learner acceptance/adoption. Additionally, no studies to date have evaluated the usefulness of a mobile-based spaced learning curriculum within an internal medicine residency program. As such, the goal of our study was to assess the effectiveness and acceptance of a mobile-based spaced learning curriculum within a graduate medical education environment.

SETTING AND PARTICIPANTS: Utilizing a mobile-based application, Qstream, that incorporates an adaptive spaced learning platform, we created an adjunct curriculum to supplement our existing academic didactics for housestaff during their critical care rotation at Walter Reed National Military Medical Center (WRNMMC). The curriculum consisted of 100 high-yield core knowledge questions within the area of critical care medicine. Each learner enrolled in the module received an email and/or RSS feed prompt daily to their mobile device of preference (smartphone, tablet) with 5 questions. Upon answering each question, a brief explanation of clinical reasoning was provided and the learner was anonymously shown their performance in comparison to their cohort. Questions that were answered incorrectly were asked again within 7 days until answered correctly twice, whereas questions initially answered correctly were asked again within 13 days. Questions answered correctly twice in succession (mastery of material) were retired.

DESCRIPTION: We conducted a prospective, randomized, controlled study of 30 interns and residents rotating on the medical and surgical intensive care units at WRNMMC. All participants had their baseline knowledge assessed by a 25 question pre-test based upon the core knowledge topics within our spaced learning module. Sixteen learners were randomized to participate in the spaced learning curriculum (in addition to traditional didactics) and were enrolled within the module. Fourteen learners were randomized to the traditional academic didactics alone. Block randomization was used to minimize cross-communication between learners. All participants completed a 25 question post-test at the conclusion of their 4 week rotation. Learners who were randomized to participate in the spaced learning module answered an additional 10 questions regarding the perceived effectiveness and usability of the module.

EVALUATION: Our cohort consisted of 18 PGY-1's (60 %), 5 PGY-2's (17 %), 6 PGY-3's (20 %), and 1 PGY-4 (3 %). Baseline characteristics (PGY level) were similar between randomized groups. Performance on the pre-test examination was comparable (61 % +/- 18 % vs 68 % +/- 17 %, $p=0.26$). Post-test performance was superior within the spaced learning group (86 % +/- 11 % vs 71 % +/- 13 %, $p=0.002$) as was the percent improvement from pre-test to post-test (18 % +/- 12 % vs 7 % +/- 13 %, $p=0.03$). The spaced learning module received favorable reviews both in terms of overall educational benefit (average rating 4.44 on a 5-point Likert scale) and as an adjunct to traditional didactics and bedside teaching (average rating 3.56 on a 4-point Likert scale). The average time to complete the 5 daily questions was 4.25 min. The overall difficulty and number of questions administered daily were designated as "appropriate" by 81 % and 87 % of learners, respectively.

DISCUSSION/REFLECTION/LESSONS LEARNED: In our cohort, we observed a statistically significant improvement in overall post-test performance within the spaced learning group. Furthermore, acceptance and perceived usefulness of the mobile-based platform was high among learners. This novel approach to traditional didactics may be useful as a means to supplement existing curricula. Additional measurements, such as in-service and ABIM exam scores, gathered from larger, multi-center trials are needed to confirm the overall utility of a spaced learning curriculum as an educational adjunct within graduate medical education.

NOT TOO MUCH, NOT TOO LITTLE, BUT JUST RIGHT: GOLDLILOCKS ROUNDS AT THE CAMBRIDGE HEALTH ALLIANCE Rachael E. Bedard^{1,2}, Alison B. Rapoport^{1,2}, Maren Batalden^{1,2}. ¹Cambridge Health Alliance, Cambridge, MA; ²Harvard Medical School, Boston, MA. (*Tracking ID #1940038*)

NEEDS AND OBJECTIVES: The ACGME identifies "Systems-Based Practice" (SBP) as a core competency for internal medicine residents; sub-competencies described in this domain include providing cost-effective care, recognizing system errors and advocating for systems improvement. Through the new Clinical Learning Environment Review program, the ACGME expects training institutions to engage residents in efforts to ensure that their delivery system is providing safe, high quality, evidence-based care to patients. With these mandates, training programs across the country seek to build meaningful curricular opportunities for residents in this domain. The "Goldilocks Rounds" at the Cambridge Health Alliance provides an innovative forum for Internal Medicine residents to discuss cases involving the overuse, underuse and misuse of healthcare resources and to design and implement small tests of change. The objectives of these rounds are as follows: - To provide a forum for honest disclosure and discussion of clinical errors and system failures - To encourage residents to identify examples in their own practice of the overuse or inappropriate use of healthcare resources -To help residents articulate one improvement oriented "action item" from each rounds that residents have the power to implement in real time

SETTING AND PARTICIPANTS: The Cambridge Health Alliance (CHA) is an integrated public healthcare system comprised of two community hospitals and an extensive primary care network. The internal medicine residency has 8 residents in each of the PGY-1, 2 and 3 years; there are an additional 8 psychiatry interns and 7 transitional-year interns who also train on one 32-bed inpatient medicine teaching unit. All residents are invited to monthly Goldilocks Rounds. The two chief medical residents facilitate rounds. Hospitalist teaching faculty are present to offer guidance; an open invitation is extended to nursing staff.

DESCRIPTION: Goldilocks Rounds are scheduled during lunch hour at regular intervals throughout the year. Housestaff come to rounds prepared with recent stories from their own practice that exemplify the overuse or misuse of medical resources, situations in which a clinical error was made, or a system failure occurred. An unnecessary blood draw, a misunderstanding with a nurse: Trainees are encouraged

not to accept these issues as byproducts of a complex health system but to identify them as areas for improvement and come up with solutions. During Goldilocks Rounds, participants select 1-2 pressing problems raised in the case discussion, brainstorm potential interventions, and commit to taking some individual or group action. Facilitators help formulate discrete, simple, positive interventions that are within the scope of the residents to enact. When applicable, chief residents lead the group in filing a formal occurrence report to model the importance of reporting errors. Residents are the primary physicians on this dedicated inpatient teaching unit; they interact consistently with the same group of nurses and ancillary staff and can exercise genuine leadership in changing the practice environment. Action items that have resulted from Goldilocks Rounds during this academic year include patient education about how to ask for PRN medications in the hospital and improved end of shift signout protocols between day and night resident teams.

EVALUATION: Prior to the first Goldilocks Rounds all house officers were invited to complete a survey on their attitudes and perceived self-efficacy regarding SBP and quality improvement. Sixty percent of residents responded. The same survey will be administered at the end of this academic year to assess change in attitudes and self-efficacy in these domains. Residents are informally invited to offer feedback on Goldilocks Rounds to the chief residents throughout the year. Finally, the chief medical residents follow up each rounds with a synopsis of issues discussed and proposed interventions. Chief residents audit the implementation and efficacy of those interventions going forward, unless a specific resident champion is identified.

DISCUSSION/REFLECTION/LESSONS LEARNED: Baseline survey results revealed that 43 % of respondents report feeling "very comfortable" discussing a medical error with a fellow housestaff. Only 21 % are "very comfortable" filing a formal occurrence report. Only 22 % currently feel "very comfortable" raising issues about healthcare costs and use of medical resources with their attending physician. Despite this, 72 % of respondents report that they "strongly agree" with the statement "My role as a physician includes a responsibility to improve the system of care in which I practice". Certainly this enthusiasm for systems-improvement work is evident in the Goldilocks Rounds discussions where trainees are eager to volunteer experiences and generate improvement suggestions. The Goldilocks Rounds are a promising strategy for bringing systems-based practice into the residency curriculum in a practical, relevant way that impacts both resident learning and patient care.

ONLINEMEDED: MOVING MEDICAL KNOWLEDGE OUT OF THE CLASS ROOM AND ONTO THE INTERNET Dustyn E. Williams. ¹Medical Education Online L3C, New Orleans, LA; ²Tulane University, New Orleans, LA. (*Tracking ID #1896418*)

NEEDS AND OBJECTIVES: There is much to learn in medical school. The shift in recent years from primarily medical knowledge to promoting a more well-rounded physician has not lessened how much knowledge must be taught, only burdened medical schools and students alike; compressing more into less time. The need, then, is a means by which the medical knowledge component of medical school can be more efficiently delivered to medical students. The goal of this project was three fold. First, it was to consolidate and filter a vast amount of medical knowledge into the medical student level, as defined by the NBME and USMLE. Second, it was to create a method for dissemination that was both cost-effective and immediately scalable. Third, it was to introduce a mode of instruction that could prove fruitful for standardized testing examination as well as clinical practice, but in a completely novel way using the internet.

SETTING AND PARTICIPANTS: Onlinemeded.org is a non-profit website that is available to everyone for free. Anyone is permitted to participate. There is no enrollment, no signup, and no cost. The only barrier is an internet connection that can support online streaming video.

DESCRIPTION: 250 online videos, each approximately 15 min long, are displayed in a one-stop-shop access website. There are 19 categories that span across the core clerkships for the third and fourth years including neurology, psychiatry, medicine, surgery, pediatrics, and the subspecialties. Each page is dedicated to a single video and includes key concepts and errata, a discussion board, and an embedded YouTube Video. Each video is constructed to educate to a medical student, at the medical student level, including the use of advanced organizers, algorithms, and memory tools.

EVALUATION: Google Analytics and YouTube Dashboard Manager were used. Each month over 6,000 unique visitors visit the site and over 24,000 videos are watched. The demographics are equal between men and women, and are primarily from the United States, with centers of use clustering around major cities: New Orleans, New York, and Chicago. Male and female users are equal. Feedback from users has revealed a

tremendous amount of anecdotal success from the use of the site. Students comfort level on the wards increases, satisfaction in education increases, and scores on the USMLE Step 2 have shown substantial improvement from their Step 1 scores

DISCUSSION/REFLECTION/LESSONS LEARNED: The demand for a resource like this is overwhelming as shown by the sheer number of users. The cost to maintain such a site is negligible; hosting videos on YouTube is free, and the cost of data for the actual site is minimal. The time cost to develop, film, and edit these videos is the primary barrier. However, once completed, they exist indefinitely until updates are required. This system provides a highly effective way of delivering medical knowledge content to medical students at extremely low cost, that is immediately scalable to every medical student in the world, and in a time-efficient manner, allowing medical schools to focus on the practice of medicine and cultivating future physicians rather than the emphasizing the basics of medical knowledge.

OUTPATIENT MORNING REPORT IN THE EHR ERA: AN OPPORTUNITY TO APPLY ADULT LEARNING THEORY TO THE AMBULATORY CURRICULUM James O'Keefe, University of California, Los Angeles, Los Angeles, CA. (Tracking ID #1928226)

NEEDS AND OBJECTIVES: The ambulatory curriculum for internal medicine residents is distributed across several venues, of which the Outpatient Morning Report (OMR) provides a unique opportunity to learn from cases from the resident clinics. Our objective was to enhance the learner-centered format of OMR by identifying multiple resident cases organized around a central theme for each session.

SETTING AND PARTICIPANTS: OMR is a 45-minute conference that is attended by 25 residents (PGY2/PGY3) on ambulatory rotations. The conference is led by a chief resident and attended by a faculty preceptor.

DESCRIPTION: The assigned resident chooses a case and notifies the chief resident of the topic. The chief resident performs an EHR search to identify similar cases from the clinics of residents who are attending the conference. Our EHR (Epic Systems) generates "reports," with search criteria including demographics, diagnoses, medications, tests ordered, vital signs and lab values. Cases are printed and the relevant content is highlighted. During OMR, the assigned resident has 20 min to present their case(s) and lead a group discussion. Next, the chief resident distributes the "surprise cases" to individual residents, who are asked to present the highlighted portions of their cases to the group. The chief resident leads a nonjudgmental discussion of learning points from each case, provides an overview of relevant articles/resources, and allows for commentary by the faculty preceptor. Example: The assigned resident presented three patients for whom advance directives could have been (but were not) discussed in clinic: a 34 year-old with relapsed AML, a 76 year-old with dementia, and a "healthy" 57 year-old. The resident reviewed relevant articles from AFP and JAGS. Next, the chief resident led a discussion of "surprise cases" comprising several patients in which DNR status was documented in clinic but not acknowledged upon subsequent hospital admission. The group focused on potential QI projects to improve code status visibility in the EHR.

EVALUATION: Conference topics are tracked in a spreadsheet to avoid duplication. High-yield topics are identified and repeated across groups of residents.

DISCUSSION/REFLECTION/LESSONS LEARNED: We have applied adult learning theory by using our EHR to identify cases for OMR. We emphasize the relevance of GIM topics by drawing cases from resident clinics; we identify knowledge gaps during the process of chart review; and we direct teaching to the needs of the learners. By splitting conference time between the resident and chief resident, we maintain audience interest and balance topic selection. We are also able to include innovative topics (e.g. cost conscious care or systems-based care) in our curriculum. An unanticipated benefit of the format is near-100 % conference attendance, as residents do not know if one of their patients is chosen as a "surprise case." The primary challenge is preparation time, which used to search for "surprise cases" (1–2 h) and prepare content (1–2 h). The amount of time has been lessened by asking residents to pick topics within the area of expertise of the guest faculty; this improves faculty engagement and reduces the amount of time for the chief resident to prepare content. A second limitation is that topics must be drawn in the resident practice and our EHR search for certain topics (e.g. refugee health) have yielded insufficient cases for a conference.

PACT ICU - INTERDISCIPLINARY CARE CONFERENCES FOR HIGH RISK PRIMARY CARE PATIENTS William G. Weppner^{1,2}; Janet V. Willis²; Amber Fisher²; Adam Brotman²; Rick Tivis²; Timothy Gordon²; C. Scott Smith^{1,2}.

¹University of Washington, Boise, ID; ²Boise VAMC, Boise, ID. (Tracking ID #1938812)

NEEDS AND OBJECTIVES: Workplace interdisciplinary collaboration is recognized as an important part of quality primary care and favorable patient outcomes. However, many health professions training programs provide inadequate opportunities for trainees to develop the knowledge, skills, and attitudes needed for this. Interdisciplinary Case Conferences can address this gap by providing opportunities for participants from multiple professions to learn with, from and about each other through discussion of real patient cases and actionable strategies for care plans.

SETTING AND PARTICIPANTS: The Boise VAMC Centers of Excellence in Primary Care Education developed the "PACT ICU" (Patient Aligned Care Team Interdisciplinary Care Update) to improve care of high risk patients in primary care. Based at our teaching clinic of approximately 32 medical residents and other trainees serving more than 2,000 patients, this offers a conference to develop coordinated, patient-centered care plans and reinforce principles of interdisciplinary collaboration.

DESCRIPTION: On a weekly basis, rotating physician and nurse practitioner trainees lead discussion of a high risk patient selected from the top five highest risk patients as predicted by the VA-based Care Assessment Needs registry. A clinic-based registered nurse uses a web-based schedule and guide to facilitate selection and review of patients. The nurse and a physician lead coordinates an hour-long conference with interdisciplinary team members, including medicine residents and attendings, nurse practitioner trainees and supervisors, primary care nurses, pharmacists, psychologists and behavioral health staff, social workers and chaplain service.

EVALUATION: Over the first 8 months of the PACT ICU, 27 trainees have participated, presenting 40 patients with 160 controls. There has been consistent involvement by different disciplines and trainees; surveys of 27 PACT ICU trainee participants suggest effectiveness at teaching PACT principles within a clinic team. The response to the statement "My understanding of all of the elements (biological, social psychological) that must be considered in this patient's care" increased from 2.8 to 4.6 out of 5 ($n=27, p<0.001$). The response to the statement "My understanding of the roles that each of the team can play in hard to manage patients like this one" increased from 3.0 to 4.5 ($p<0.001$). Chart review of consult patterns suggests an increase in referrals to other members within the PACT team, such as pharmacy and behavioral health. Among patients that were presented in the PACT ICU, consults outside the team were 18 % lower than controls and consults to team members (pharmacy, psychology, social work, and RN case manager) increased. This consult pattern is emerging across all patients, suggesting generalizability of interprofessional collaboration. Using case-control methods, data from the first 6 months of this pilot indicates a non-significant trend towards decrease in patient utilization when compared to controls in the PCP's panel with similar risk scores for ER visits (0.94 vs. 1.20 per patient per year, $p=0.48$) and hospitalization (0.34 vs. 0.49 per patient per year, $p=0.38$).

DISCUSSION/REFLECTION/LESSONS LEARNED: These findings suggest that PACT ICU has reinforced key patient-centered medical home concepts within an academic primary care setting, improving trainee understanding and referral patterns within the team. Overall, an interdisciplinary care conference such as PACT ICU can be a useful model for (1) teaching interdisciplinary care, (2) facilitating team-based care, and (3) improving patient consult management.

ONLINE RESOURCE URL (OPTIONAL): Online Care Assessment Needs registry (VA-intranet based risk prediction tool) Online Care Management Tool 3.0.0 (VA- intranet based care management tool) Online PACT ICU schedule & tools: <http://moodle2.boisevacoec.org>

PANEL MANAGEMENT IN ACADEMIC PRACTICES: WHAT IS IT THAT WE REALLY NEED TO TEACH? Kate Dube¹; Rachel Willard-Grace¹; Janhavi Athavale²; Thomas Bodenheimer¹; Reena Gupta³. ¹University of California, San Francisco, San Francisco, CA; ²Eastern Virginia Medical School, Norfolk, VA; ³University of California, San Francisco, San Francisco, CA. (Tracking ID #1939756)

NEEDS AND OBJECTIVES: Panel management entails identifying and facilitating needed chronic and preventive care for a population of patients using clinical guidelines. In high-performing primary care practices, panel management is usually conducted by non-clinician members of the team, often medical assistants (MAs) or nurses who work closely with the clinician, relieving some of the routine patient care burden. Little is known about how panel management services are structured in teaching practices, which are charged not only with providing high quality care for patients, but also with teaching their residents requisite clinical and interdisciplinary leadership. We sought to understand how panel management is implemented in teaching practices.

SETTING AND PARTICIPANTS: We conducted site visits at ten primary care residency clinics. Data was collected using a structured site visit guide and semi-structured interviews with clinic leadership, providers, trainees, and clinic staff. Site visit reports were coded and analyzed via matrix by two independent researchers through an iterative process. The research team reviewed these analyses to identify themes.

DESCRIPTION: Two primary panel management models emerged: 1) Residents provide panel management to their assigned patients; or 2) Medical assistants and other allied health professionals provide panel management for the residents' patients. The first model facilitates learning clinical guidelines, and it provides residents with an understanding of the process of panel management, such that they would understand what their MAs or nurses were doing as they entered the workforce upon completion of their training. On the other hand, the second model reinforces a team-based model of care that is more compatible with many contemporary primary care practices, and it provides an opportunity to build resident skills in leading a team. One site implemented a promising hybrid model that addressed both training residents in clinical skills and in team-based care. In this model, the residents and medical assistants share the panel management responsibility, work together to track patients who are in need of care and conduct outreach calls together.

EVALUATION: Additional research is needed to understand how to define best practices and what patient and resident outcomes are associated with each model.

DISCUSSION/REFLECTION/LESSONS LEARNED: Faced with the dual missions of training residents both in necessary clinical skills and in interdisciplinary team-based care models, teaching clinics have alternately entrusted panel management responsibilities to residents or MAs and nurses. A hybrid model, in which residents work collaborative with MAs or nurses, may provide a useful mode to bridge these models and achieve these dual missions.

PAP EMPHASIS CLINICS: AVENUE TO IMPROVE CANCER SCREENING RATES AND TRAIN RESIDENTS IN WOMEN'S HEALTH Michelle Cleeves; Rebecca Hamratty; Sarah Christensen; Jennifer Adams. Denver Health and Hospital Authority, Denver, CO. (*Tracking ID #1938721*)

NEEDS AND OBJECTIVES: Needs and Objectives: Though cervical cancer is easily preventable with regular screening, there are roughly 12,000 new cases of advanced cervical cancer annually in the United States. A significant cause of this failure to screen is that women are not offered cervical cancer screening by their primary care doctors, and studies have demonstrated this is especially likely when those care providers are recently graduated from residency. Though the ACGME and ABIM both require training and competency in preventive care counseling and specifically in delivery of pap smears, a deficiency persists in the provision of cervical cancer screening. By creating a "pap emphasis" clinic with specific curriculum and focused patient care for our residents, we aim to increase resident exposure to pelvic exams and cervical cancer screening with the goals of improving both resident education and cervical cancer screening rates in an urban underserved resident training clinic.

SETTING AND PARTICIPANTS: Setting and Participants: PGY1, 2, and 3 internal medicine residents are scheduled to participate in the pap emphasis clinics at their continuity clinic site once during a 6 month intervention period.

DESCRIPTION: Description: 14 patients are scheduled per session and residents perform pelvic exams, pap smears, STI testing, and family planning counseling as indicated. Residents also received a curriculum delivered by a GIM faculty member with expertise in women's health which includes review of pap screening guidelines, pathophysiology of cervical cancer development, preventive health care screening guidelines, and wet prep microscopy during their pap clinic.

EVALUATION: Evaluation: We are assessing change in attitudes and medical knowledge with a 10-question survey administered to each resident before and after the curriculum is delivered. Topics contained in the survey included cervical cancer screening guidelines, pap smear results interpretation, and slide identification of common wet prep pathology. All 15 residents with continuity clinic at the pilot site will be scheduled to participate in the pap emphasis clinics throughout the study period. The session begins with a brief didactic session followed by direct patient care. We conclude the session with microscopy review of wet preps and a post-test. Although this project is ongoing, we have preliminary analysis demonstrating significant improvement in resident comfort with pelvic exams and medical knowledge in the areas tested. The residents also report high levels of satisfaction with the curriculum. At the same time, the pap rates increased in the pilot clinic sites demonstrating an impact on patient care.

DISCUSSION/REFLECTION/LESSONS LEARNED: Discussion/Reflections/Lessons Learned: Though cervical cancer screening is effective in prevention of invasive cervical cancer, there continue to be gaps in screening rates. Previous studies have demonstrated this is due in part to poor rates of physician implementation, especially among recent residency graduates. By creating a pap emphasis clinic, we were able to increase access to care for our patients and provide targeted teaching of pap smears and other preventive care topics in women's health, a skill set which will be carried forward into independent clinical practice.

PATIENT SAFETY AT THE MOVIES Chaitanya Mandapakala^{1,2}; Diane L. Levine^{1,3}. ¹Detroit Medical Center, Detroit, MI; ²John D Dingell VA Medical Center, Detroit, MI; ³Wayne State University, Detroit, MI. (*Tracking ID #1938570*)

NEEDS AND OBJECTIVES: In the Institute of Medicine landmark report from 2001, "To Err is Human and Crossing the Quality Chasm", the importance of teaching principles of quality improvement and patient safety throughout the continuum of undergraduate, graduate, and continuing education was emphasized. The Association of American Medical Colleges further recommends integrating these concepts as early as the first year of medical school. Efforts are presently underway to recognize important attributes students should possess at graduation from medical school called "Core Entrustable Professional Activities for Entering Residency" (CEPAER) for all entering residents to perform without direct supervision on day one of residency, regardless of specialty. Among these activities the ability to identify system failure and contribute to a culture of safety and improvement has been deemed as being critical. Wayne State University is the largest single campus medical school in the USA with 300 students per class. Third year medical students are assigned to a 2-month Internal Medicine (IM) clerkship at one of eight clinical sites. This makes teaching patient safety challenging. This year we initiated a patient safety half-day workshop to provide an opportunity for students to learn the principles of quality improvement and patient safety during their IM clerkship. Our medical school was very supportive of this endeavor, but was unable to provide financial support. So we developed a hands-on-experience utilizing low cost easily purchasable episode of a popular television show.

SETTING AND PARTICIPANTS: Students on the clerkship were required to attend a half-day patient safety workshop in the middle of their clinical rotation unless they had their continuity clinic.

DESCRIPTION: A pre-test was administered at the start of the workshop to test 7 basic concepts of quality improvement and patient safety. The session began with a case based presentation (morning report) providing an opportunity to discuss critical and latent medical errors, situations where errors are more probable while emphasizing concepts such as importance of proper transition of care and medication reconciliation. Students were encouraged to participate and identify how these errors could be avoided. Using a variety free resources demonstrating quality improvement from industry and personal stories the curriculum was delivered. Cases were examined to understand how the quality and patient safety department analyzes using various quality improvement techniques to strengthen the system. The high point of the day was the showing of a Grey's Anatomy episode (cost \$2.99) entitled "I saw what I saw". Popcorn was distributed and lights were dimmed; students enjoyed the episode and participated in making a process map and a root cause analysis based on the events depicted in the episode. Possible solutions and PDSA cycles were described to further understand these principles. A post-test asking the same questions as the pretest was completed at the end of the workshop. Individual pre- post-test scores were analyzed.

EVALUATION: To date three workshops have been conducted. A total of 132 medical students participated. Of the 132 students who attended, 120 (90.9 %) students completed pre and post tests. Analysis of pre-tests showed that 75 % of students were able to give examples of situations where medical errors are more probable. The majority of students (75–99 %) showed knowledge deficits in the remaining concepts tested. All students showed knowledge improvement in all quality improvement and patient safety concepts discussed through this workshop (Swiss Cheese Model of Errors - 97.78 %, Situations where medical errors have higher probability to occur - 100 %, Sentinel Events - 98.75 %, construction of fishbone diagram - 97.48 %, RCA - 95.37 %, PDSA - 86.44 %). Based on feedback received after the first two workshops, the concept of human factors engineering was discussed in more detail during the third workshop with knowledge improvement of 96.42 %. Students also recorded 129 medical errors observed during their first month of clinical clerkship which were then classified into 10 categories. Medication errors (42 %) were the most common type. Interestingly only 1 student reported lack of hand hygiene as a patient safety concern. Finally, at the end of the workshop, 100 % of the students either agreed or strongly agreed to "I am knowledgeable about patient safety". Qualitative analysis of the student comments indicated that the students found the workshop to be enjoyable and informative.

DISCUSSION/REFLECTION/LESSONS LEARNED: The approach used targeted integrating quality improvement and patient safety thinking into daily workflow. This half day patient safety workshop has proved to be an accessible, feasible, inexpensive and successful way to introduce junior students to the concepts of patient safety and quality improvement.

PATIENT-CENTERED MEDICAL HOME FOR SICKLE CELL DISEASE: IMPACT ON UTILIZATION OF ACUTE CARE SERVICES Temeia Martin; William P. Moran; Patrick D. Mauldin. Medical University of South Carolina, Charleston, SC. (*Tracking ID #1940183*)

NEEDS AND OBJECTIVES: Patients with sickle cell disease (SCD) have a life-limiting illness with a chronic relapsing course characterized by painful crises and recurring need for acute care for treatment. We sought to create a SCD outpatient medical home at the Medical University of South Carolina (MUSC) including acute care, individual care plans for each patient including acute treatment protocols and chronic medication regimens, and measure impact on emergency department (ED) visits and hospitalizations.

SETTING AND PARTICIPANTS: University Internal Medicine (UIM) is an NCQA-certified level III PCMH and hospital-based clinic responsible for the care of almost 10,000 medical patients with diverse medical conditions, comorbidities, and behavioral risk factors. Half of the 30,000 annual patient visits occur in the Internal Medicine resident continuity clinic, and half in the contiguous faculty practice with the majority of SCD patients assigned to the resident clinic. We defined our SCD medical home population as a patient seen 2 more times in the UIM practice over the preceding 3 years.

DESCRIPTION: An interdisciplinary team was brought together to provide focused care to SCD patients by way of a patient-centered medical home. Patients were tiered according to their patterns of utilization for enrollment in the SCD medical home. We sent letters asking them if they would like to transfer their care from the UIM practice to the SCD medical home and a follow-up phone call was made. Patients who consented attended a 1 h intake appointment and were scheduled for monthly visits thereafter. Follow-up visits were used to address issues related to SCD, co-existing chronic medical conditions, and health care maintenance. Patients were also given access to acute daily treatment of their pain with intravenous narcotics and hydration. We developed a referral process for medical home patients who presented to the ED. Plans of care for treatment of acute and chronic pain were individualized. A pharmacy clinic was developed for management and monitoring of Hydroxyurea usage in the patient population. We developed a transition plan with pediatrics to support matriculation to adult care. The population included in the SC medical home increased from a pilot of 10 patients to 78 over the first 20 months. The interdisciplinary team met weekly to coordinate ongoing development strategies for the clinic.

EVALUATION: Baseline data demonstrated that SCD accounted for 1 % of the UIM practice and accounted for 15 % of ED visits, 10 % of hospital admissions, and 33 % of re-hospitalizations. Measures of success were utilization of ED and hospital, Hydroxyurea prescribing, and patient satisfaction. Three patients died before the program started and 2 have died since its initiation. Interrupted time series (ITS) pre-post comparison design was used to assess change in utilization and data were limited to MUSC system. Statistically significant decreases in ED utilization ($p<0.0001$) were achieved for the top 40 utilizers within the UIM PCMH Sickle Cell clinic following implementation of the clinic. Because of the small sample size, large fluctuations did not allow for significance to be determined for hospitalizations or re-hospitalizations. To determine where the effect on ED utilization of the sickle cell clinic was the strongest, subgroup analyses were performed: top 7 utilizers, next 16 utilizers, and then the remainder of the top 40. Significant decreases in ED utilization were achieved for the top 7 utilizers ($p=0.0006$), with the most significant decreases within the “next 16” utilizers ($p<0.0001$). There was no increase in Hydroxyurea prescriptions from baseline although there was an improvement in monitoring for toxicity and dose adjustments to target goals. Patient satisfaction data is gathered through qualitative and quantitative mechanisms including surveys and focus groups.

DISCUSSION/REFLECTION/LESSONS LEARNED: Implementation of a patient centered model in SCD appears to have a positive impact on disease management. Greater access to acute and longitudinal medical services improves utilization of acute care services. Patterns of utilization correlate with severity of disease underscoring the need for enhanced models of care for SCD.

PRE-CLINICAL ELECTIVE TEACHES END-OF-LIFE COMPETENCIES: EFFECTS PERSIST INTO CLINICAL YEARS Melissa S. Keepert; Brian Cruz. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #1927107*)

NEEDS AND OBJECTIVES: Medical education inadequately addresses end-of-life (EOL) and palliative care. We previously reported that our intervention—a pre-

clinical elective—increased students’ self-perception of readiness to discuss EOL-related issues following completion of the course. The first cohort of intervention students to complete a significant clinical year was assessed to determine if their readiness continued 2 years after taking the course. Our aims were: 1) teach medical students basic EOL care competencies with an emphasis on confidence-building for addressing these topics with patients and their families; and 2) measure the impact of this elective from the pre-clinical (MS-1 and MS-2) years to the clinical (MS-3 and MS-4) years.

SETTING AND PARTICIPANTS: We designed an elective open to first-year medical students at Tulane University School of Medicine. We have implemented it for three consecutive years, starting with the Class of 2014 in their MS-1 year. This cohort has now completed its first and main clinical year of medical school. We administered a survey to the entire Class of 2014 upon completion of their MS-1 year and upon completion of their MS-3 year to assess EOL competencies. Course participants’ responses were compared to control students who did not take the elective.

DESCRIPTION: The elective is open to 25 medical students for 10 total course hours. Creative, active-learning modules are combined with published tools and techniques to explore the basics of hospice and palliative medicine. Multiple domains are addressed using a combination of didactics, group discussion, standardized patients, attendance at the hospital ethics committee meetings, and site visits. The elective utilizes student leadership of MS-3 and MS-4 students, expertise of Tulane’s palliative care specialist on faculty, education by internal medicine residents pursuing fellowships in palliative care, and other multidisciplinary specialists.

EVALUATION: Medical students who completed the elective in their MS-1 year said they felt more prepared to speak to patients and/or patient families about EOL issues than their counterparts, with 78 % of elective students responding “prepared” compared to only 32 % of controls; $p<0.001$. These responses persisted 2 years later into the “clinical” training years, where 70 % of MS-3 students who had taken the elective responded “prepared” compared to only 36 % of students who had not taken the elective; $p<0.05$.

DISCUSSION/REFLECTION/LESSONS LEARNED: The increased comfort and ability to speak about EOL-related issues that students achieved following their participation in the MS-1 elective has persisted into their clinical years. This student-initiated elective exemplifies the usefulness and high impact of teaching clinically-relevant skills early in the pre-clinical curriculum.

ONLINE RESOURCE URL (OPTIONAL): <http://tmedweb.tulane.edu/mu/eol/eol-elective/>

PREPARING RESIDENTS FOR THE PRIMARY CARE MEDICAL HOME: SELF-DIRECTED, LONGITUDINAL PROJECTS IN QUALITY IMPROVEMENT Carol Sprague^{2,1}; Christine Mullaney¹. ¹Oregon Health and Science University, Portland, OR; ²Portland Veterans Affairs, Portland, OR. (*Tracking ID #1938533*)

NEEDS AND OBJECTIVES: A core principle of the primary care medical home is ongoing engagement in quality and safety activities. Resident training needs to prepare young physicians for this work. We therefore designed and implemented projects in quality improvement with the following objectives: 1) To familiarize residents with the concepts and strategies of the patient-centered medical home 2) To foster the development of creative, systems-based solutions to challenges in clinical care 3) To practice use of the electronic health record in capturing population data and supporting the delivery of evidence-based care

SETTING AND PARTICIPANTS: The Internal Medicine residency at the Oregon Health & Science University (OHSU) is a university-based, mid-sized program. The OHSU ambulatory curriculum includes a primary care clinic experience (for which we have three sites) as well as ambulatory based rotations, one of which is the “Chronic Illness Management” or “CIM” rotation. In addition to a team-based clinical experience, the CIM rotation includes a 2 h weekly session to learn the principles of the medical home. Residents are scheduled for 6 of these sessions over a 6 month period; interns are given a 3 month period to work on a QI project.

DESCRIPTION: The initial sessions include interactive lectures on the patient-centered medical home and the PDSA tool. Residents then apply these concepts toward a self-directed quality improvement project. In deciding upon a project topic, residents account for the structure and patient demographics of their primary care site. Residents develop an “aim statement” and think through each step of a PDSA. They use the medical literature for guidance about benchmarks. Residents then obtain the best performance data available within their clinic setting. Clinic teams are involved in the improvements when possible. Project development is achieved through an

interactive, iterative experience in which residents return on a monthly basis to reflect on their progress and to receive feedback from peers. At the final session, residents present their quality project to their peers and are asked to reflect on how they might accomplish their goals with a larger patient panel.

EVALUATION: Resident evaluations of the rotation are positive. Residents appreciate applying the QI concepts to their own patient panels and clinic settings, a process that in one resident's words "helped me realize the potential . . . to make significant changes in my practice." Developing projects that are appropriate in three different clinical settings is challenging but helps residents learn about different systems of practice. Last academic year, three residents were selected to present their projects at a Medicine department M&M. The flexibility of the project allows residents to develop skills within the context of their interests and in keeping with their stage of development as a physician.

DISCUSSION/REFLECTION/LESSONS LEARNED: The quality improvement project in the "CIM" rotation provides residents with a longitudinal, self-directed learning experience. Quality improvement concepts seem to be learned well when residents are given flexibility in determining a topic that will be meaningful to them. Our current structure is restricted by each clinic's capacity to incorporate significant quality projects and by our ability to access accurate data in each setting. Ideally, for those residents with a particular interest, we would propose the development of a separate rotation that allows residents to contribute to clinic-wide, interprofessional efforts toward quality improvement.

PROGRESS TESTING: AN INNOVATIVE APPROACH TO ASSESSMENT OF COMPETENCY-BASED MILESTONES IN CLINICAL SKILLS Lauren Block; R. Ellen Pearlman; Judith M. Brenner; Alice Fornari; Joseph S. Weiner; Marie Barilla-Labarca. Hofstra North Shore-LIJ School of Medicine, New Hyde Park, NY. (*Tracking ID #1933537*)

NEEDS AND OBJECTIVES: Growing evidence suggests that medical student assessment should be developmentally sequenced, competency-based, individualized, and integrated across disciplines. Progress testing offers an efficient, individualized, comprehensive assessment across content areas and academic year. We sought to use a single standardized case as a progress test to compare developmentally-based clinical skills competencies among medical students.

SETTING AND PARTICIPANTS: As the culmination of a longitudinal clinical skills curriculum, a single standardized case was administered in a clinical skills center to first and second year students at Hofstra North Shore-LIJ School of Medicine.

DESCRIPTION: Students performed a history and physical examination on a standardized patient as well as a post-encounter exercise to assess competency in domains including communication, patient care, and professionalism. A committee of standardized patients and clinical faculty reviewed student performance based on proposed milestones expected for the student's year in each domain.

EVALUATION: 58 first year and 33 s year students completed the examination. 81 % (47) of first-year and 85 % (28) of second-year students met developmental expectations in communication, 90 % (52) and 94 % (31) in patient care, and 84 % (49) and 76 % (25) in professionalism. The 23 students who did not meet expectations were offered remediation through individual feedback, videotape review, and a repeat exam. The implications of these data will be discussed.

DISCUSSION/REFLECTION/LESSONS LEARNED: A single standardized case served as a developmental progress test to identify students attaining milestones in clinical skills and highlight areas for feedback and remediation. Standardized patients and faculty cooperated to identify areas of weakness and offer individualized feedback to learners. As developmental milestones are proposed in medical education, it is critical to evaluate whether students meet the recommended competencies. We designed a single case to serve as an integrated clinical skills progress test. Future work will include prospective development of a competency-based instrument for longitudinal assessment in clinical skills.

REACHING CONSENSUS AMONGST PHYSICIANS IN BUILDING AN EVALUATION TOOL TO IMPROVE DISCHARGE SUMMARIES AND OPTIMIZE TRANSITIONS OF CARE Karim Taha; David W. Frost. University Health Network (UHN), Toronto, ON, Canada. (*Tracking ID #1936760*)

NEEDS AND OBJECTIVES: The discharge summary is an essential communication tool between hospitalists and primary care physicians. Despite advances in electronic transfer of discharge summaries as well as electronic templates, there

remain challenges around optimization and standardization of its content. This study aimed to reach consensus amongst family physicians (or general practitioners, GPs) on the relative importance of various components of the discharge summary, and to determine the best areas to focus educational efforts. Based on these results, an evaluation tool for discharge summaries was developed for both educational and quality assurance purposes.

SETTING AND PARTICIPANTS: Twenty-five family physicians (both academic and community-based) participated in our study employing the Delphi methodology of consensus building based on iterative surveying. This initiative was a partnership between the General Internal Medicine Division of the University Health Network in Toronto and family physicians in Toronto, Ontario and surrounding regions.

DESCRIPTION: Three rounds of surveys regarding discharge summaries were completed. The first round allowed for family physicians to express open-ended opinions about the most salient aspects of discharge summaries. The second round asked participants to rank all opinions generated from the previous round in terms of importance and agreeability to their preferences. Finally, the last round addressed any outlier responses in the overall rankings. The culmination of these rounds served to establish a refined average in each discharge summary category. Findings: Specific instructions for the family physician in the follow-up section and a well-outlined discharge plan were areas of highest relevance to participants. These sections were also noted as least clearly filled out currently. Commonly reported areas requiring improvement included the need for a thorough medication reconciliation section, a concise overall report, and provision of specialist referral information. Participants expressed preference for inclusion of relevant lab results from the entire hospital stay duration, and suggestions were made on appropriate educational interventions to maximize discharge summary quality.

EVALUATION: The tool developed will be subjected to an assessment of intended outcome (improved discharge summary quality), implementation and uptake levels, and determination of perceived value to educators and learners. Feedback generated will guide further revisions and dissemination decisions.

DISCUSSION/REFLECTION/LESSONS LEARNED: Family physicians, as experts in the evaluation of discharge summary quality, purposely engaged with general internal medicine physicians in the successful development of an educational and quality improvement tool using rigorous consensus-building methodology. Deployment of the tool is currently under way in paper and electronic form. Evaluation of its utility in improving discharge summary quality is planned in the near future. With an almost 100 % response rate throughout three rounds of surveys, our ranked results are highly reflective of the collective opinions of partnering family physicians.

RESIDENT AS PRECEPTOR: DEVELOPING SENIOR RESIDENTS' AMBULATORY TEACHING SKILLS AS PART OF A RESIDENT AS TEACHER CURRICULUM Elena Lebduska¹; Sudha Dubey²; Darlene LeFrancois¹; Sheira Schlaier¹. ¹Montefiore Medical Center, Bronx, NY; ²Beth Israel Medical Center, New York, NY. (*Tracking ID #1937669*)

NEEDS AND OBJECTIVES: Fostering residents' teaching skills can complement clinical skill development for internal medicine residents. While there are many opportunities for inpatient resident teaching skill development, opportunities to expand teaching skills may be underutilized in ambulatory settings. Our aim was to teach residents effective precepting skills in the ambulatory setting by providing a "Resident as Preceptor" curriculum followed by supervised precepting sessions with junior residents.

SETTING AND PARTICIPANTS: Third year internal medicine residents on a "Resident as Teacher" elective, first and second year internal medicine residents, and attending internal medicine physicians in three ambulatory internal medicine sites at Montefiore Medical Center (Bronx, NY).

DESCRIPTION: The "Resident as Teacher" elective is an intensive 2 week rotation focused on resident teaching skill development in which residents receive formal teaching skill instruction and are observed and given feedback in diverse teaching encounters. The "Resident as Preceptor" curriculum is a major focus of our "Resident as Teacher" elective. A two-hour learner-centered, multimedia curriculum focuses on adult learning theory, socratic method, the "one-minute preceptor" model, and RIME scheme. Following the didactic session, residents then precept for 1–2 half days. During these sessions the resident precepts a junior (PGY1 or PGY2) resident while an attending physician silently observes. All participants complete evaluation forms and give immediate feedback on the resident preceptor's precepting skills.

EVALUATION: Resident preceptors, junior residents and attending physicians are surveyed immediately following each precepting session to assess overall precepting effectiveness. Survey instrument outcomes are based on principles of the "one-minute

preceptor" model and the RIME scheme with all questions scored on a 1–4 Likert scale (1 = strongly agree to 4 = strongly disagree) or open-ended questions. To date, 13 senior residents, 15 junior residents and 7 attending physicians have participated with the goal of 25 senior residents, 30 junior residents and 10 attending physicians having participated by Spring 2014. Of the initial participants, 66 % of residents and 62 % of attending physicians "strongly agreed" that the resident preceptors effectively elicited the junior residents' reasoning, assessment, and plan. Seventy percent of residents "strongly agreed" that they were comfortable in their role as preceptor, and 80 % "strongly agreed" that the experience added educational value to their residency. Seventy-five percent of junior residents "strongly agreed" that they received behaviorally specific feedback.

DISCUSSION/REFLECTION/LESSONS LEARNED: Interim analysis of survey and program evaluation data suggests that a learner centered curriculum focused on feedback and precepting skills, and observed precepting experience with immediate feedback on teaching skills, can add educational value to the residency experience. In addition, initial cohorts of resident preceptors seem to have been effective at applying lessons learned in the didactic portion of the curriculum, including principles of adult learning theory and learner assessment. Resident preceptors found it to be an overall rewarding experience. Incorporating resident precepting skill development into a "Resident as Teacher" curriculum can expand educational and assessment opportunities to the ambulatory setting.

RESIDENTS JOIN THE HUDDLE: RESIDENT PARTICIPATION IN A QUALITY IMPROVEMENT PROJECT ON RN-MD COMMUNICATION DEVELOPS SEVERAL ACGME RESIDENT COMPETENCIES Rachel Hathaway¹; Maren Batalden¹; Priyank Jain¹; Kathleen M. Clark². ¹Cambridge Health Alliance, Cambridge, MA; ²Cambridge Health Alliance, Cambridge, MA. (*Tracking ID #1930039*)

NEEDS AND OBJECTIVES: Increased attention to developing resident proficiency in quality improvement has led to the inclusion of competency in quality improvement as an ACGME milestone. Quality improvement efforts emphasize interdisciplinary collaboration in clinical work; the capacity to work in teams is a competency required for the 21st century physician. This project involves residents helping to design and implement a structured, daily nurse-physician "huddle" on an inpatient teaching service to proactively communicate patient care plans at the start of each day. Resident leaders will be instrumental in structuring and evaluating the impact of this intervention. We intend to show that the active participation of Internal Medicine residents at Cambridge Hospital in a quality improvement project allows residents to meet the ACGME milestone of systematically analyzing their practice and engaging in practice improvement. Additionally, several other secondary competencies are strengthened through participating in this project.

SETTING AND PARTICIPANTS: This pilot project will take place on a busy inpatient teaching service at Cambridge Hospital, a university-affiliated, community hospital in an urban, diverse, and largely underserved setting. The service is resident-run and exclusively geographically located on one floor of the hospital, allowing for consistent interactions between residents and a defined cohort of nurses. Participants in the nurse-physician huddle include 2nd and 3rd year residents, all floor nurses, the nurse manager, and the unit secretary.

DESCRIPTION: Currently, MD's and RN's primarily communicate with one another via ad-hoc interactions. We intend to institute a daily, structured, and brief "huddle" between residents and nurses at the beginning of the day shift. The intent of this resident-led huddle is to address early in the shift any nursing or patient concerns, potential discharge complications, and to clearly communicate the patient care plan for the day to all relevant providers. Any patients identified as being sick or complex will prompt inclusion of the nurse on MD work rounds to ensure a cohesive team approach. All participants will be encouraged to be engaged and proactive in their roles. Summaries of each patient will be high-yield and concise. Real-time feedback will be solicited from both residents and nurses in order to rapidly improve care and anticipate problems. Objectives of the huddle include improved communication between residents and nurses, improved patient care, better teamwork, and improvement in both RN and MD satisfaction with their work environment.

EVALUATION: There will be several tiers of evaluation. Residents will be quantitatively surveyed regarding their perceived growth in various ACGME competencies including quality improvement. Additionally, we will assess the value residents place on quality improvement and other related competencies as a result of participating in the project. Both residents and nurses will be evaluated regarding any perceived improvement in nurse-physician communication, teamwork, quality of patient care, and work environment satisfaction. Patient satisfaction will be surveyed via changes in Press Ganey scores.

DISCUSSION/REFLECTION/LESSONS LEARNED: Finding meaningful ways for residents to develop competency in the realm of quality improvement is a priority. This is reflected in the current ACGME milestones. This quality improvement pilot project seeks to actively engage Internal Medicine residents at Cambridge Hospital in improving nurse-physician communication on a busy inpatient ward. Nurse-physician communication is improved by means of a structured, daily morning "huddle" to address active, patient-centered concerns. This resident-led initiative provides opportunity to develop and demonstrate competency in several ACGME milestones, including acting as patient advocates, striving for excellence in patient care, successfully participating in interprofessional teams, and practicing effective communication. Residents not only observe the inner workings of a quality improvement initiative but are critical players in the process. Residents will be encouraged to reflect on the impact that their work has had on their own development as leaders, on the culture of the unit in which we work and on patient care.

RESTORING EMPHASIS ON AMBULATORY INTERNAL MEDICINE TRAINING - "THE 3:1 MODEL." Joshua W. Harrison; Peter Cronkright; Astha Ramaiya. Upstate Medical University, Syracuse, NY. (*Tracking ID #1910892*)

NEEDS AND OBJECTIVES: Inadequate ambulatory training in internal medicine (IM) residency programs may be partially responsible for the current shortage of primary care physicians. Without an adequate ambulatory care experience, IM residents fail to observe the rewarding nature of developing continuity relationships with their patients and do not gain the confidence and experience to be effective outpatient practitioners. With work hour demands and multiple reports citing concerns regarding ambulatory IM training, reform in this arena is necessary.

SETTING AND PARTICIPANTS: A relatively novel 3:1 scheduling system that creates week long ambulatory blocks every fourth week was instituted for PGY-2/3 residents at our program. During this week residents participate in morning continuity clinic and afternoon subspecialty clinic training. Residents begin ambulatory days learning practice management issues, reviewing an ambulatory medicine article, covering a pharmacy topic, or reviewing a physical exam skill. Each quarter residents participate in a half day "Teaching Activity" allowing faculty to directly observe residents communicate with simulated patients, role play clinical teaching scenarios, or run simulated codes.

DESCRIPTION: We hypothesized that this model would provide a more structured ambulatory educational atmosphere, better continuity of care, more exposure to subspecialty outpatient medicine, and eliminate conflict with inpatient duties. We hoped this would enhance resident satisfaction with ambulatory medicine and achieve our main goal of improving the ambulatory educational experience.

EVALUATION: Surveys were created utilizing a Likert scale and distributed 9 months into this experience. Responses from PGY-1's maintained on a traditional $\frac{1}{2}$ day per week clinic schedule were compared to PGY-2/3 responses using a *t*-test. The PGY-2/3 group also retrospectively evaluated their experience in the 3:1 model compared to the prior year's traditional schedule. These results were analyzed descriptively. Residents reported the 3:1 model had positively affected their satisfaction with residency training in general, their satisfaction with outpatient/primary care training, and their outpatient/clinic educational experience. Residents perceived improvements in continuity of care with patients and in the quality of care they provided for patients. Their experience in ambulatory sub-specialty training was positive. PGY-1's who remained on a traditional $\frac{1}{2}$ day per week clinic schedule were significantly less satisfied than PGY2/3's with their ambulatory/primary care training (mean=3.48 vs. 4.08, *p*=0.01). Compared to PGY-2/3's, PGY-1's also perceived less continuity of care with their patients (mean=3.91 vs. 4.38, *p*=0.03), less adequate exposure to sub-specialty outpatient medicine (mean=3.0 vs. 4.58, *p*≤0.01), and were more distracted or worried about inpatient duties while at clinic (mean=2.39 vs. 4.92, *p*≤0.01).

DISCUSSION/REFLECTION/LESSONS LEARNED: We present positive results following the institution of a relatively novel 3:1 scheduling model. This system effectively eliminates the concurrent demands of inpatient and outpatient duties, provides increased time for educational sessions, has improved resident satisfaction in several arenas, likely promotes continuity of care, and provides important exposure to subspecialty outpatient medicine. We believe these changes enhance our residents' ambulatory educational experience. Given the resoundingly positive results the 3:1 model has since been instituted for all categorical residents at our program.

SEALS: A PROCESS AND INTERMEDIATE OUTCOME EVALUATION OF AN INNOVATIVE PIPELINE CURRICULUM Cassandra D. Fritz; Monica Vela. University of Chicago, Chicago, IL. (*Tracking ID #1936651*)

NEEDS AND OBJECTIVES: Pipeline programs are one proposed method to increase the number of under-represented minority (URM) students matriculating to medical school. Although pipeline programs have demonstrated success in increasing matriculation of URM students, a review conducted by the Department of Health and Human Services in 2003 notes the lack of appropriate evaluation measures for pipeline curriculum. Therefore, our goals were to 1) develop an evaluation mechanism using process and intermediate outcome measures for pipeline programs and 2) apply the evaluation to a novel pilot pipeline program.

SETTING AND PARTICIPANTS: The SEALS summer pipeline program is a novel curriculum established to promote 5 competencies among minority medical students including: Socialization and Professionalism, Education in science learning tools, Acquiring finance literacy, Leveraging Mentorship and Networks, and Social expectations and resilience. Local academically successful URM and/or underserved rising first and second year college students were recruited to apply through the web. IRB approved pre/post program surveys included short answer, likert scale responses, and personal statement writing and were administered to the 13 SEALS students. In addition, this survey was administered to a cohort of ten students in a comparable, research-based pipeline program at our institution during the same summer session. This cohort served as a control.

DESCRIPTION: The pre and post survey instrument included qualitative and quantitative measures designed to assess students' knowledge, skills, attitudes, and quantify hours of programmatic activities. Students' knowledge of (1) the medical school admissions process, (2) requirements for medical school, (3) AMCAS application service, (4) Health Care Disparities, and (5) Anatomy and Physiology of systems related to greatest health threats to underserved populations was assessed. Skills of how to (1) shadow a physician effectively, (2) seek out research opportunities, (3) engage and reflect upon service opportunities, (4) develop a personal statement of interest in medicine, (5) interview and communicate, and (6) effectively complete a financial aid form were also assessed. The survey gauged the students' attitudes toward the following: (1) service, (2) research, (3) medicine as a profession, and (4) commitment to medicine as a career. Finally, the total number of hours spent on each activity and student's assessment of the quality of the activities was obtained.

EVALUATION: Our evaluation consisted of process and intermediate outcome measures. Process measures included who participated, quantity of activities, and quality of those activities. Intermediate outcome measures quantified students' change in knowledge, skills, and attitudes. The evaluation was also administered to the control cohort, who did not differ significantly in any demographic when compared to the SEALS cohort. Process Outcomes. One hundred percent of students agreed/strongly agreed that the Meet the Professor series, Health Care Disparities series, and Pre-Med 101 workshops were instrumental in motivating students to pursue their passion for medicine (11 of 11). Furthermore, these curriculum components inspired students to advocate for minority health issues. Intermediate Outcomes. The pre-SEALS to pre-control analysis did not reveal any important statistically significant difference between the two cohorts. A comparison of pre-SEALS to post-SEALS found statistically significant changes favoring post- SEALS: knowledge of MCAT components ($p=0.007$), ability to ask for letter of recommendation ($p=0.04$), attitudes toward research being an important determinant of success ($p=0.02$) and appearing confident during an interview ($p=0.04$). The post-SEALS to post-control did uncover a number of statistically significant values including, but not limited to ability to communicate with patients ($p=0.046$), understanding of health disparities ($p=0.04$), understanding of major disease entities ($p<0.01$), and students' resolve to become a physician ($p<0.01$). Pre and post- SEALS personal statements were compared to the control group's AMCAS personal statement using a 5-point scale. The SEALS cohort average score increased by nearly 1 point. (pre=2.09 to post=2.95). These averages were then compared to the control cohort average, which was determined to be 2.40.

DISCUSSION/REFLECTION/LESSONS LEARNED: Two major lessons about pipeline curriculum emerge. First, defining best practices in pipeline curriculum requires process and intermediate outcome measures. Outlining process and intermediate outcome measures of pipeline programs will allow for systematic improvement of program practices and dissemination of successful pipeline practices. Second, use of a control group revealed a gap in professional development training for URM students participating in research-based pipeline programs.

SHARED DECISION MAKING IN CHRONIC CONDITIONS: A CURRICULUM IN USING DECISION AIDS FOR INTERNAL MEDICINE RESIDENTS
Leigh H. Simmons^{1,2}; Lauren Leavitt^{2,1}; Alaka Ray¹; Blair W. Fosburgh¹; Karen R. Sepucha^{2,1}. ¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital, Boston, MA. (Tracking ID #1936903)

NEEDS AND OBJECTIVES: In the current medical environment, there is heightened attention to training physicians in communication skills that will enhance patient understanding of treatment recommendations and reduce "preference misdiagnosis." The aim of this study was to develop and implement an educational workshop for residents to promote shared decision making (SDM) with their patients during clinical interactions, with a specific focus on decision making for four chronic conditions (diabetes, depression, hypertension, and hyperlipidemia).

SETTING AND PARTICIPANTS: We conducted our study in a large academic internal medicine residency; 120 residents (from all years of training) participated during their ambulatory rotation.

DESCRIPTION: We used a mixed methods approach to understanding our residents' perspectives on SDM, improving resident knowledge about SDM, and implementing a novel paper decision aid for resident training. We ran focus groups with residents to elicit challenges of decision making with patients for chronic conditions and to get feedback on a new tool, the Choice Report. The Choice Report is a single-page print decision aid that highlights six steps of shared decision making, including FAQs about treatment options. Using the focus group insights, we developed a workshop curriculum including the following: a didactic presentation about risk communication, introduction of the Choice Report to guide conversations about chronic conditions, and role-playing exercises for a chronic condition using the Choice Report. Participants were shown how to download the Choice Reports from the hospital's primary care-focused intranet (accessible by all clinicians). Participants completed surveys after the session and we tracked the number of times that Choice Reports were downloaded.

EVALUATION: 120 residents attended the workshops over a 4-month period. The interns rated the workshop higher than the residents (81 % very useful content & 62 % excellent overall rating vs. Forty-six percent very useful content & 41 % excellent overall rating). This trend has been observed in our previous workshops, in which interns have generally found the content of shared decision making discussions more useful and rated them more highly than the 2nd and 3rd year residents. The Choice Reports on diabetes, depression, hyperlipidemia, and hypertension were downloaded 1500 times in the 8 months following their introduction.

DISCUSSION/REFLECTION/LESSONS LEARNED: The workshop introduced residents to a SDM communication strategy for routine clinical encounters, with a focus on decision making for chronic conditions. This curriculum was novel in that it introduced a SDM tool to clinical topics not previously recognized as candidates for a "shared decision making" approach. The Choice Reports also generated significant interest from our general medicine clinicians and have continued to be used regularly in the course of routine primary care. We had initially planned to include a component of direct observation, with preceptors completing a mini-CEX of a visit using a Choice Report. However, we found that coordinating direct observations of eligible encounters was prohibitively difficult. Because this tool has been accepted and used by our staff and resident clinicians, we are developing new Choice Reports, to include cancer screening decisions, additional chronic conditions, and multiple language translations.

SIGUIENDO ADELANTE: A MEDICAL SPANISH CURRICULUM FOR RESIDENTS Avik Chatterjee¹; Li Qin²; Jaideep S. Talwalkar³. ¹Harvard Pilgrim Health Care Institute/Department of Population Medicine at Harvard Medical School, Cambridge, MA; ²Yale School of Public Health, New Haven, CT; ³Yale University, New Haven, CT. (Tracking ID #1931760)

NEEDS AND OBJECTIVES: Spanish speakers with limited English proficiency (LEP) represent a large and growing part of the population in the United States, with 80 % of hospitals providing care to LEP patients regularly. Having a language-concordant provider is associated with improved patient satisfaction and improved processes of care. Previously described medical Spanish curricula have improved language skills among students and practicing physicians, but these curricula are incompatible with resident schedules. In 2009, a needs assessment at our institution showed that residents saw Spanish-speaking patients regularly and wanted a medical Spanish curriculum designed for residents. Objective: 1) Demonstrate improvement in medical Spanish for a diverse group of residents 2) Improve cultural competency

SETTING AND PARTICIPANTS: Our institution is a 1,541 bed tertiary-care hospital with over 500 resident physicians, in a city of 129,585 people, of whom 27.4 % self-identify as Hispanic. In 2010–2011, we created a pilot curriculum with 20 participants from internal medicine, pediatrics, and combined med-peds programs. The curriculum was well received, so in 2011–2012 we expanded our learner-base, offering the curriculum to residents in their second year or above from all programs at our institution. Participants also were required to have at least a conversational level

of Spanish. We had 63 participants, 33 (52 %) of whom were from procedural specialties.

DESCRIPTION: The year-long, self-directed curriculum contains nine month-long modules, with 3 months that residents can take off during particularly demanding clinical rotations. The curriculum includes practice with a variety of skills including grammar, vocabulary, reading, writing, listening comprehension, speaking and cultural competency, in keeping with the principles of adult second-language learning, which suggests that incorporating multiple learning modalities is most effective. Each month-long, systems-based module includes: a grammar/vocabulary activity; a health-related DVD program; patient cases with a Spanish-speaking tutor; and community practice sessions. The community practice sessions involve having participants prepare health education talks on various topics to practice with English as a Second Language (ESL) students at a local non-profit, getting the chance to practice vocabulary, speaking and listening comprehension skills, while improving understanding of cultural concerns that would arise from the patient population that our residents serve.

EVALUATION: We conducted pre-intervention and final assessments of language skills and cultural competency using previously validated self-report questions. We also collected open-ended feedback from participants and tutors. Of 63 participants, 13 (21 %) responded to the final survey. Of those, nine (71 %) were satisfied or very satisfied with the curriculum, but only five (38 %) completed a majority of the modules. Every respondent cited time as a barrier. There were correlations between number of modules completed and self-reported fluency scores ($p=0.025$), change in self-reported receptive language ability ($p=0.025$), and self-reported understanding of the health-related cultural beliefs of Spanish speaking patients ($p=0.047$). Residents in cognitive specialties were more likely than residents in procedural specialties to complete the post-course evaluation ($p=0.03$).

DISCUSSION/REFLECTION/LESSONS LEARNED: We developed and implemented a novel medical Spanish curriculum for residents in order to address the prevalent health disparities issue of communication with Spanish-speaking LEP patients. Residents at our institution recognized the need for specific training to improve language concordance and expressed a desire for a medical Spanish curriculum that fit their schedules. Our institution, recognizing the need, supported our intervention. Our study demonstrated that residents who completed more of the curriculum had better self-reported fluency scores and cultural competency skills. The majority of residents who provided feedback were satisfied with the YRSI and several were able to complete significant parts of the curriculum. However, while residents from multiple specialties were initially enthusiastic about the availability of the curriculum, they ultimately found it difficult to participate, primarily citing time constraints. For future participants, we plan greater clarity about time required, more documentation of completion of curricular materials, frequent reminders, and large-group events to encourage a sense of team. We will also include more surgery-specific activities. Ultimately, measurement of the curriculum's impact on patient outcomes will also be important. While curricular revision is necessary, we believe that the implementation of a flexible, self-directed curriculum is a feasible way to incorporate Spanish language education into a traditional residency schedule, at our institution and others.

STORY TELLING: MY MOST MEMORABLE PATIENT - LESSONS IN HUMANISM, REFLECTION, AND THE DEVELOPMENT OF EXPERTISE
Priya Radhakrishnan^{1,2}; Patti Thorn^{2,1}. ¹St Joseph's Hospital & Medical Center, Phoenix, AZ; ²Creighton University School of Medicine, Phoenix, AZ. (Tracking ID #1937664)

NEEDS AND OBJECTIVES: Needs : Humanism in medicine is heavily stressed in undergraduate medical education, particularly within the first and second years of medical school. Yet, when residency begins, there is a gradual erosion of cognitive attention to humanism and the values that initially attracted physicians in training to the profession of medicine are set aside in favor of acquisition of knowledge, patient management, and efficiency. The reduction in duty hours, opportunities for continuity of care, and a relatively young faculty mentor group only accentuate the erosion of attention to humanism and lived expression of meaningful values. In addition, there is a need for physicians in training to be challenged to progress in clinical problem solving abilities along a continuum toward expertise, and, learning to tap into episodic memories of actual patients has been demonstrated to serve this progression. Objectives- 1. To revitalize the humanistic aspect of medicine within Internal

Medicine residents 2. To encourage deep reflection and meaningful attention and focus on the primary values of medicine, which when lived frequently, translate to increased career fulfillment 3. To encourage the practice of episodic memory formation which is utilized in advanced clinical problem solving

SETTING AND PARTICIPANTS: Setting & Participants The curriculum has been instituted in the St Josephs Internal Medicine residency program since 2010. It is a series of 3-4 conferences at the end of the academic year. Each third year resident actively participates in the storytelling

DESCRIPTION: All residents anticipate and plan to present a patient or patients that touched them during their training experience. The patients they present are framed as "those that will never be forgotten for the teaching and learning they inspired." Residents receive a list of learning objectives and a bulleted list of reflection prompts to aid their reflection process. The presentation format is left entirely up to the residents-they may use a Powerpoint or engage in narrative-story telling (the latter is encouraged). The audience includes multi-disciplinary teams from both the inpatient and outpatient care settings, hospital staff, administrators, educators, nurses, hospital leadership and medical students. Following the residents' shared reflections and narrative, the audience is encouraged to comment and share their thoughts about the impact the story telling had, memories and learning recalled, and similar patient care experiences. These sessions are highly anticipated as a culmination/capstone to the residency training program. Resident participants as well as the audience engage in collective humanism and discussion of the value that form the core of medical professionalism. Residents also reflect on how the learning from their patient has shaped their decision-making and how they anticipate the memory will become significant in their careers as physicians.

EVALUATION: The sessions are evaluated on the response that it generates in the residents and the audience. Both groups are asked to share in writing the value(s) that were evoked by the capstone presentation. Several of the essays have been published by residents in different venues. Audience comments and the narratives are collected and we plan to publish a collection of the best essays in reflection. We also plan to start a Story-Corp collection of the narratives to archive these collections.

DISCUSSION/REFLECTION/LESSONS LEARNED: As the practice of medicine and residency training is transforming in response to the societies' call for decreased duty hours, there is great danger of the loss of humanism among physicians in training due to the toll of rapid cycle change. In addition, amongst junior and even seasoned faculty, we are observing disillusionment and burnout leading to career attrition. This capstone curriculum is designed to re-invoke the humanism in medicine and bring together team members who may not see the patient but are invested in the success of the enterprise: leaders as well as physicians and the multi-disciplinary team

STORYTELLING WITH INPATIENTS Katherine C. Chretien^{1,2}; Rebecca Swenson³; Bona Yoon¹; Rickie Julian⁴; Jonathan Keenan²; Raya Kheirbek^{1,2}. ¹Washington DC VAMC, Washington, DC; ²George Washington University, Washington, DC; ³Dartmouth-Hitchcock Medical Center, Lebanon, NH; ⁴Montefiore Medical Center, Bronx, NY. (Tracking ID #1938337)

NEEDS AND OBJECTIVES: Empathy is an essential component of patient-centered care and improves patient outcomes. A recent systematic review of interventions to teach empathy to medical trainees identified a need for future interventions to be built upon a foundation of relationship-centered care. Narrative competence can be defined as "the ability to acknowledge, absorb, interpret, and act on the stories and plights of others." There are few published educational interventions that address empathy while involving actual patient-provider interactions, and/or address narrative competence. We sought to incorporate a brief experiential narrative medicine curriculum within the third-year medicine clerkship with the goals of developing narrative competence, practicing attentive listening, and stimulating reflection while providing patient-centered care for hospitalized patients.

SETTING AND PARTICIPANTS: Single institution with third-year basic medicine clerkship students on a 4 week rotation and inpatients on the acute (non-ICU) medicine wards.

DESCRIPTION: The narrative medicine curriculum consisted of 1) Introductory session where students were introduced to narrative medicine and practiced attentive listening to storytelling in pairs; 2) Patient activity where students elicited illness narratives from patients, attentively listened, wrote their version of the story, and then read these back to patients. Students also asked patients to select a piece of art to help tell their story, chosen from a digital collection stored on an iPad. 3) Debriefing/reflection session where students wrote reflectively and participated in a facilitated discussion about their experiences with the activity.

EVALUATION: To evaluate and help assess acceptability and feasibility of the curriculum, five focus groups were held between July 2011 and March 2012. Thirty-one students participated. Transcripts were qualitatively analyzed for themes by two independent researchers; disagreements were resolved through discussion. Students discussed their patients' reactions to the narrative medicine activity, students' own experiences, the student-patient dynamic, and challenges. They also identified what they felt they learned, including seeing the patient as human, being open, and clinically relevant insights. Students felt that the activity improved the student-patient relationship and, in some cases, powerfully so. Response to the art component was mixed; for some student-patient pairs, the art the patient chose brought new insights into patient understanding. For other pairs, the technology and/or image library created barriers. Interviews with patients revealed generally positive response, although some patients did not recall the activity. Several patients asked their students to be their primary care provider. Comparison of audiotaped patient stories to the corresponding written narratives penned by students is ongoing to assess students' narrative competence.

DISCUSSION/REFLECTION/LESSONS LEARNED: A brief, experiential narrative medicine curriculum was feasible and acceptable to students and patients. From a time and resource perspective, the curriculum took 2 h of faculty time per month. Both patients and students appear to have yielded benefits - for patients, being attended to and being heard; for students, gaining deeper appreciation of the human side of medicine, of knowing patients better. The impact on the student-patient relationship was often positive, at times powerfully so. Ongoing focus groups helped to make continual improvements to the curriculum, including the retirement of the iPad art component and refinement of how the patient activity was structured to maximize comfort of both students and patients.

TEACHING INTERPROFESSIONAL TRAINEES TO WORK IN CLINICAL CARE TEAMS: THE SAN FRANCISCO VA CENTER OF EXCELLENCE IN PRIMARY CARE EDUCATION Rebecca L. Shunk^{1,3}; Bridget O'Brien¹; Maya H. Dulay^{1,3}; Terry Keene^{2,4}; Denise L. Davis^{1,3}; Shalini Patel^{1,3}; Melissa Bachhuber^{1,3}; Calvin L. Chou^{1,3}; Kristen Weaver^{2,4}; Christina Kim^{2,4}; Lynn O'Brien^{2,4}. ¹UCSF, San Francisco, CA; ²UCSF, San Francisco, CA; ³San Francisco VA Medical Center, San Francisco, CA; ⁴San Francisco VA Medical Center, San Francisco, CA. (*Tracking ID #1936850*)

NEEDS AND OBJECTIVES: Primary care clinics at the San Francisco VA (SFVA) transitioned to an interprofessional team-based model of patient care called Patient Aligned Care Teams (PACTs) in 2010. In 2011 the SFVA was awarded a Center of Excellence to develop and implement an innovative model of patient-centered, interprofessional education in a team-based ambulatory clinic. The core educational domains addressed in our center include sustained relationships, performance improvement, patient-centered communication, and interprofessional collaboration.

SETTING AND PARTICIPANTS: In July 2011, we added trainee squads (2 s-year internal medicine residents and 1 s-year nurse practitioner student) to each of 8 pre-existing "teamlets" (1 registered nurse, 1 clinical associate, 1 clerical associate) in three SFVA primary care clinics. Each trainee acts as primary provider for a personal panel of patients but performs cross-coverage for squad members. Teamlets and squad members discuss team patients in daily huddles or brief meetings along with other interprofessional trainees.

DESCRIPTION: Curricular design for the core domains includes didactics, workplace reinforcement and reflection. For example, we set the foundation for interprofessional collaboration through interactive seminars on team members' roles, conflict negotiation and huddling, then reinforce these skills in the workplace through daily huddles and interprofessional clinical practice. Team-building retreats provide opportunities to learn and practice skills together; to learn about each other both professionally and personally; and to reflect on teamwork, all requirements of high-functioning teams.

EVALUATION: To assess interprofessional collaboration, members of all trainee teams were asked to complete the Team Development Measure (TDM). The TDM is a tool created by Peace Health and used by the VA for PACT evaluation nationally scored on 0–100 scale. Team members evaluate how their team is functioning in terms of cohesiveness, communication, role clarity and goals and means clarity. Team members complete the TDM early and again later in the academic year and have an opportunity to review and discuss their results during a facilitated session. Scores improved from early year to late year (Year 1–59.4 early/64.6 late) and they started and ended up slightly higher in year 2 compared to year 1. (Year 2–62.4/70.4 late) In June 2013 the first cohort of internal medicine residents graduated and were asked to

rate their experience on a 5 point Likert scale with 5 being strongly agree. They rated "effectiveness of working with trainees from other health professions (i.e. pharmacy, psychology, social work, nutrition) to provide quality patient care" 4.5 and "the educational value of opportunities to work with trainees from other health professions" 4.19. Patient surveys indicate a high level of satisfaction equivalent to other VA providers locally and nationally. When asked "using any number from 0 to 10, where 0 is the worst provider possible and 10 is the best provider possible, what number would you use to rate this provider?" 73 % and 76 % of residents' and NP students' patients respectively rated their provider either a 9 or 10.

DISCUSSION/REFLECTION/LESSONS LEARNED: Trainee clinical care teams can learn about and improve team functioning through a curriculum involving didactics, workplace reinforcement and reflection. Interprofessional trainees can successfully work and learn together to deliver team-based care creating positive experiences for trainees and patients alike.

TEACHING PATIENT-CENTERED ELECTRONIC MEDICAL RECORD (EMR) USE TO MILLENNIAL LEARNERS: ARE WE PREACHING TO THE CHOIR? Wei Wei Lee; Lolita Alkureishi; Jeanne M. Farnan; Vineet Arora. University of Chicago, Chicago, IL. (*Tracking ID #1937618*)

NEEDS AND OBJECTIVES: Studies demonstrate that Electronic Medical Record (EMR) use in exam rooms can prevent providers from focusing on patients and be detrimental to patient-doctor communication. Despite rapid EMR adoption, few curricula address how to teach patient-centered EMR use to 'tech-savvy' millennial learners. In 2013, we implemented a 'Patient-Centered EMR Use' curriculum for second-year medical students (MS2s), which consisted of a lecture and Observed Structured Clinical Exam (OSCE). We aim to assess the impact of our curriculum. Our objectives are to: 1) Compare OSCE performance of MS2s, who received the lecture, to third-year medical students (MS3s), who did not receive training on this topic. 2) Compare MS2 and MS3 post-OSCE survey scores on self-assessed knowledge, attitude and skills.

SETTING AND PARTICIPANTS: We implemented a 'Patient-Centered EMR use' curriculum for MS2s which consisted of a 1 h lecture and an OSCE to allow for skills practice. MS3 students served as historical controls; they did not receive the lecture but did participate in the OSCE as part of a required year-end multi-station OSCE exercise.

DESCRIPTION: The MS2 lecture was integrated into a required Clinical Skills course. The OSCE required students to: 1) log into the EMR and review relevant records; 2) address the patient's chief complaint and; 3) use the EMR to counsel the patient on obesity. MS2s participated in a group OSCE (1 student interacted with the Standardized Patient (SP), 3 students observed). MS3s participated in individual OSCEs, where each student directly interacted with the SP. An 'SP evaluation tool' was developed to assess OSCE performance. The SP evaluated every student he directly interacted with during the OSCE. Post-OSCE self-assessment surveys were distributed to all students. MS2s' performance on the OSCE and self-reported knowledge, attitude and skills was compared to the historical control group of MS3s who did not receive training.

EVALUATION: 45 MS2s attended the lecture, 88 participated in the group OSCE ($n=20$ students who directly interacted with the SP; $n=68$ student observers), and 80/88 (91 %) post-OSCE surveys were analyzed. Ninety-six MS3s participated in the OSCE and 88/96 (92 %) post-OSCE surveys were analyzed. 96 % (77/80) of MS2s and 85 % (75/88) of MS3s agreed (≥ 3 on 5 point scale) that the topic was at least moderately 'important to their current training.' 55 % (44/80) of MS2s rated their knowledge as good or excellent compared to 19 % (17/88) of MS3s. 39 % (31/80) of MS2s rated their training as good or excellent compared with 14 % (12/88) of MS3s. 87 % (70/80) of MS2s reported moderate confidence (≥ 3 on 5 point scale) compared with 73 % (64/88) of MS3s. Overall, 85 % (68/80) of MS2s and 70 % (62/88) of MS3s agreed or strongly agreed that 'training should be required for all students.' The 'SP evaluation tool' consisted of a 16-item checklist (score range: 15–80 points). The SP ratings were significantly higher for MS2s ($n=20$) than for MS3s ($n=96$) [70.8 (SD=4.3) v. 58.1 (SD=13.1), $p<0.001$]. Overall, 95 % (19/20) of MS2s were rated as good or excellent in their ability to 'use the EMR to enhance communication' compared with only 53 % (51/96) of MS3s.

DISCUSSION/REFLECTION/LESSONS LEARNED: Medical educators may assume that millennial learners are inherently tech-savvy and adept at integrating the EMR into clinical care. Interestingly, we found that MS2s who received a short lecture on patient-centered EMR use performed significantly better on an OSCE than MS3s who received no training on this topic. Our study shows that at baseline,

millennial learners may not have the skills necessary to integrate the EMR in a patient-centered manner and should be taught patient-centered EMR use.

TEACHING QUALITY IMPROVEMENT USING A CASE-BASED LEARNING FORMAT Georgia N. McIntosh; Nathan Schwartz; Steven Bishop; Michelle N. Brooks; Bennett Lee. Virginia Commonwealth University, Richmond, VA. (*Tracking ID #1933579*)

NEEDS AND OBJECTIVES: Despite years of innovation in business, and aviation, the field of QI with regards to medicine is relatively new. As such, there has been little research into the most effective teaching method. The purpose of this project is to pilot a case-based learning format for delivering QI knowledge. This interactive format lends itself to discussion and brainstorming different solutions to problems, the essential piece of developing a QI project. Through this format we aimed to teach residents the components of QI: develop a process map, define change items, create an aims statement and measures and implement and interpret data from a PDSA cycle.

SETTING AND PARTICIPANTS: This educational model is geared towards internal medicine residents but can be used for residents in any field, medical students or faculty members new to quality improvement.

DESCRIPTION: Our case-based learning format occurred over two 2-hour sessions. For the first session, participants first completed a pre-test self-assessment rating their comfort level in different aspects of QI. Residents were divided into groups of 6–7, for a total of 6 small groups. Participants were introduced to a case-a trend of intern duty hour violations during a specific rotation. After a brief overview of QI principles in healthcare, the groups were tasked with creating their own aim statements based on the given case. Using the gallery walk concept where groups post their work on the wall and each group is allowed to view and comment on each proposal, the large group then critiqued and voted on which aim statement to implement. Next, residents were given a brief review of process improvement tools (process mapping, mind maps, Ishikawa diagrams), and were tasked with mapping out a typical day for the rotation in question. After a brief review of the concept of change items and measures development, groups developed their own change items based on their aim statements. The large group again used the gallery walk concept and voted on the change items to implement. In the second session, groups were reminded of the aim statement and change items that were voted on during the previous session. They were tasked with developing their measurement items in their small group work and again voted in the large group format. Participants were then given simulated data based on the intervention they voted on. From this, the concepts of run sheets and variations in data (common cause variation, special cause variation) were introduced. Based on their analysis of this data, groups developed next action items in their PDSA cycles and voted on these.

EVALUATION: Forty-four residents completed the pre-test and 20 completed the post-test survey. To the question “how comfortable are you in your current skills with the following aspects of quality assessment and improvement”, participants answered 12 questions with the following choices: 1) not at all, 2) slightly, 3) moderately or 4) extremely.” We dichotomized the responses into either 1 and 2 or 3 and 4. For all questions, using Fischer’s exact test, respondents reported improved comfort in their quality improvement skills, most notably with using measurement to improve their skills (38 % to 85 %, $p=0.003$), identifying whether a change leads to an improvement (37 % to 70 %, $p=0.03$), and in using the PDSA model as a systematic framework for trial and learning (10 % to 55 %, 0.004).

DISCUSSION/REFLECTION/LESSONS LEARNED: Case-based learning is an engaging learning technique that can easily be applied to teaching QI. Because case-based teaching is discussion-based, it lends itself well to the ability to brainstorm different scenarios that are essential to crafting a project. With our format, we were able to effectively introduce the concepts of quality improvement in an active and engaging learning platform, as evidenced by improved self-reporting of their comfort levels. One obvious caveat to our study was the reduction in post-test survey responses, partly due to variability in conference attendance due to clinical duties as well as a lack of perceived importance of residents. We also recognize that this reports comfort level, not actual knowledge or skill. Next steps would include a means to assess knowledge of QI and the subsequent skill of performing a true project. This educational model has the potential to be used for practitioner new to quality improvement regardless of level of training.

TEACHING RESIDENTS SCREENING, BRIEF INTERVENTION AND REFERRAL TO TREATMENT SKILLS FOR ALCOHOL USE: USING CHART-STIMULATED RECALL TO ASSESS CURRICULAR IMPACT Maria A. Wamsley¹; Nathaniel Gleason¹; Michelle Guy¹; Katherine Julian¹; Patricia S. O’Sullivan^{2,1}; Scott Steiger¹; Jason Satterfield¹. ¹University of California, San Francisco, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA. (*Tracking ID #1937193*)

NEEDS AND OBJECTIVES: It is widely recognized that there is a critical need for more screening, brief intervention and referral to treatment (SBIRT) for alcohol use disorders (AUDs) in primary care settings. Barriers include inadequate provider skills and confidence as well as systems-related factors such as time pressures in the clinical setting and lack of referral resources. The optimal format for curricular interventions to address physician-related barriers remains unclear. One potential solution to systems-related issues is to better support SBIRT for alcohol use disorders using tools in the electronic health record (EHR). We implemented a 3-hour curriculum to instruct primary care internal medicine (IM) residents in SBIRT skills. We also developed a set of tools in the EHR to serve as a scaffold for the SBIRT curricular content, facilitate documentation of alcohol use, and to provide patients with tailored resources.

SETTING AND PARTICIPANTS: This study took place at an academic primary care residency program. Twenty PGY2 and PGY3 primary care IM residents participated in the curriculum and 16 participated in the evaluation.

DESCRIPTION: The curriculum consisted of two 1.5-hour sessions. We developed charting tools for the EHR (EPIC) to prompt residents to consider curricular content and to facilitate appropriate and efficient documentation of alcohol use. These included alcohol use history (HPI) and assessment and plan (A/P) charting tools and patient information resources (PI) with a list of referral resources. We introduced charting tools to learners after SBIRT curriculum completion.

EVALUATION: We evaluated the SBIRT curricular intervention utilizing chart review and chart-stimulated recall (CSR). Six months after curriculum completion, we provided residents a list of their patients seen in the preceding 12 months who were drinking at or above the recommended drinking limits and asked the residents to select up to 3 patients for review with a faculty member. Faculty reviewed charts to determine whether patients were seen in the 6-month period after curriculum completion and used a 25-item checklist to assess resident use of SBIRT skills and charting tools. Faculty met with residents individually, performed a CSR for each patient using a structured interview form and provided feedback to the residents. Residents subsequently evaluated the CSR process.

DISCUSSION/REFLECTION/LESSONS LEARNED: Sixteen residents participated in the chart review; 39 charts met criteria for our study. Residents did reasonably well at documenting alcohol use in the medical record (79 %) including quantity and frequency of use (64 %) and documenting their recommendation for patients to reduce their alcohol use (59 %). Residents correctly diagnosed the patient, documented an appropriate follow-up and plan only about half of the time. Resident reported barriers included time, resident discomfort, competing issues in the visit (medical/mental health), and perceived willingness of the patient to engage. Only 3 charts (8 %) included the use of the electronic HPI tool, 1 chart used the A/P tool, and 3 (8 %) used the PI tool. Resident reported barriers to EHR tool use included lack of awareness of the tools and lack of use of electronic charting tools in their normal workflow. Overall satisfaction with the CSR process was high; residents felt that the CSR reinforced SBIRT curriculum and provided valuable feedback and planned to make changes in their clinical practice. A more intensive curriculum with opportunities to practice skills and receive feedback over time may be required to improve skills. For EHR tools to be useful, additional reinforcement including simulation to practice integration of the tools into the visit workflow is essential.

TEACHING SAFE TRANSITIONS: A POST-DISCHARGE FOLLOW-UP PILOT FOR THIRD-YEAR MEDICAL STUDENTS Kara Bischoff; Hemali Patel; Larissa Thomas; Karen E. Hauer; Cindy Lai. University of California, San Francisco, San Francisco, CA. (*Tracking ID #1934559*)

NEEDS AND OBJECTIVES: Adverse events are common during transitions of care (TOC), including discharge from the hospital. About 20 % of patients experience

adverse events after discharge and nearly 20 % of Medicare fee-for-service patients are readmitted within 30 days. Acknowledging the critical role that the healthcare system plays in determining quality of care, medical school curricula are focusing increasingly on systems-based practice. By engaging medical students in analyzing their patients' transitions out of the hospital, we aimed to develop students' awareness and skills regarding TOC.

SETTING AND PARTICIPANTS: All third year medical students during their core medicine clerkship at University of California, San Francisco.

DESCRIPTION: Students attended a one-hour, interactive didactic session about TOC. We emphasized common adverse events that occur during TOC, risk factors for these adverse events, and evidence-based strategies to prevent them. Students reviewed the electronic medical record and called at least one patient whom they discharged from the hospital. Students used a templated note to record any common risk factors for adverse events around the time of discharge and whether the patient experienced any adverse events, including inability to obtain medications, inability to adhere to recommendations, uncontrolled symptoms, lack of intended follow-up, emergency visits, or readmissions. Students used a semi-structured phone call format using the Teach-Back Method to assess patients' comprehension of their medical conditions and treatment plan, as well as their adherence to the plan. Students reinforced healthy behaviors and communicated with primary care providers (PCPs) about any adverse events identified. Students completed a structured, written reflection about ways they will change their clinical practice based on this exercise. They identified systems issues in need of improvement. They shared their work with their inpatient team and sent a summary e-mail to PCPs. Students received quantitative and qualitative feedback from an evaluation committee, which was intended to be constructive and did not contribute to their clerkship grade.

EVALUATION: Students completed surveys before and after this curriculum. So far, 32 students have completed the curriculum. Preliminary results from 32 students who completed the pre-survey and 14 students who completed the post-survey show that the percentage of students who feel knowledgeable about how TOC occur at the time of hospital discharge increased from 31 % before the curriculum to 86 % after. The percentage of students who feel confident in their ability to identify risk factors for adverse events during TOC increased from 38 to 93 %. The percentage of students who feel confident in their ability to prevent or mitigate adverse events during TOC increased from 6 to 64 %. Eighty-six percent of students feel that this exercise fills an educational gap, and 86 % recommend continuing the exercise. The most common criticism, cited by three students, is the time required to complete this exercise. The rate of successful completion of two multiple choice questions that tested students' ability to identify and mitigate adverse events during TOC increased from 16 % and 94 % prior to the exercise to 36 % and 100 % after the exercise, respectively.

DISCUSSION/REFLECTION/LESSONS LEARNED: This pilot demonstrates that a didactic and experiential curriculum can fill an educational gap and improve students' knowledge and confidence regarding TOC.

TEACHING SHARED DECISION MAKING: IMPROVING RESIDENT COMMUNICATION THROUGH CURRICULAR INNOVATION AND OBSERVED VISITS Maryann K. Overland^{1,2}; Linda Pyke¹; Anne P. Poppe¹; Joyce E. Wipf^{1,2}. ¹VA Puget Sound Health Care System, Seattle, WA; ²University of Washington, Seattle, WA. (*Tracking ID #1927018*)

NEEDS AND OBJECTIVES: Communication skills are foundational for primary care physicians and central to patient-centered care. The literature is rich with evidence that shared decision making (SDM) is underutilized among primary care physicians, and there are no best practices for how to teach it. To strengthen the ability of medicine residents and students to engage patients in their care plan, our VA Center of Excellence in Primary Care Education (COEPCE) designed a curriculum to improve mastery of SDM. Our curriculum consisted of direct observation and brief didactics, production and review of several videos of expert clinicians, and standardized patient (SP) encounters.

SETTING AND PARTICIPANTS: In the spring of 2013, our VA COEPCE developed and implemented a half-day seminar on SDM for an interprofessional mix of trainees consisting of internal medicine residents and doctorate-level nurse

practitioner students (DNPs). The session was preceded and followed by observed clinical encounters with direct feedback from continuity clinic mentors using a validated SDM tool.

DESCRIPTION: First, faculty mentors were trained to use the OPTION tool and observed trainees during a clinic visit to assess the trainees' baseline skill in SDM. Then, trainees participated in a half-day seminar that included the following: 1. Didactic on the spirit and skills of SDM 2. Review of videos of unscripted encounters featuring local expert clinical faculty and SPs engaging in SDM. 3. A brief review of clinical guidelines and provision of fact sheets on six cases: diabetes, hypertension, breast cancer screening, depression, atrial fibrillation, and goals-of-care in terminal cancer. 4. SP encounters to practice SDM around the six cases. 5. Wrap up and feedback To maximize participants' comfort, practice time, and clinical knowledge acquisition, we created three stations where SPs alternated between two unique roles. Medicine residents and DNP students rotated through each station in pairs, practicing and observing each other. The observer and SPs provided immediate and direct feedback. After the seminar, faculty mentors again observed resident clinical encounters to evaluate SDM skill acquisition.

EVALUATION: Faculty observers reported improved use of SDM during patient encounters after the seminar. Trainees reported a meaningful increase in confidence in their ability to use SDM (per visual analog scale) and a high likelihood to use the skills acquired during this seminar (4.5/5 on a 5-point Likert Scale). They were very enthusiastic about the standardized patients and working in pairs (4.7/5 on a 5-point Likert Scale). Trainees highly valued the video demonstrations of brief encounters by experienced clinicians.

DISCUSSION/REFLECTION/LESSONS LEARNED: SDM is an important part of every primary care visit, but is a skill that is difficult to teach, often taking a lifetime to master. In this seminar, we achieved our dual-mission of providing a safe setting for practicing challenging communication skills and embedding it within clinical knowledge attainment. The design of this seminar successfully minimized knowledge differences among interprofessional learners. This innovative curriculum utilizing standardized patient encounters and real-life clinical scenarios allowed primary care physicians to strengthen communication skills around engaging patients in shared decision making.

TEACHING TEAM-BASED CARE: THE USE OF INTERDISCIPLINARY TEAM MEETINGS IN THE AMBULATORY INTERNAL MEDICINE RESIDENCY CURRICULUM Jonathan Arend¹; Stefani Russo¹; Eva Waite¹; Deborah Korenstein³; Lauren Peccoraro¹; Aparna Sarin¹; Alex Federman¹; Linda Pagan²; Theresa Soriano¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³American College of Physicians, Philadelphia, PA. (*Tracking ID #1939032*)

NEEDS AND OBJECTIVES: Amid increasing enthusiasm for team-based models of patient care, incorporation of team-based care into residency curriculum is starting to emerge. As academic primary care practices embrace the Patient-Centered Medical Home (PCMH) model and residency programs seek ways to satisfy Next Accreditation System (NAS) milestones related to team-based care, educators must develop methods for teaching the skills needed to operate effectively in interdisciplinary care teams. As part of a comprehensive PCMH curriculum, we instituted an outpatient interdisciplinary team meeting structure to support team-based care and team-based quality improvement. We sought to determine the feasibility of team meetings and assess resident satisfaction with interdisciplinary care before and after institution of the meetings.

SETTING AND PARTICIPANTS: In our academic primary care practice at the Icahn School of Medicine at Mount Sinai in New York, NY, internal medicine residents are assigned to 1 of 3 firms, in which they provide patient care and work with firm-based attending physicians, medical assistants, registered nurses, nurse practitioners, social workers, care coordinators, patient navigators, and front desk registration staff. In July 2013, we implemented weekly team meetings in each firm, attended by members of each of the above disciplines. All residents attended their respective team meeting during ambulatory blocks.

DESCRIPTION: We developed the format of the team meetings based on literature review, collaboration with other academic medical centers, and local priorities. Prior to initiating the firm-based meetings, we held several "all-staff" meetings, in which

residents, general internal medicine faculty, and clinic staff were trained in principles of teamwork, effective meeting skills, and quality improvement methodology. We redesigned the resident schedule and clinic staffing to provide 1 h per week of protected time for the meetings. The meetings were co-led by a registered nurse and an attending physician and focused on team communication, clinical workflows, practice initiatives, and quality improvement.

EVALUATION: Before implementing the meetings, we surveyed all residents to assess their satisfaction with interdisciplinary care at the practice. Sixty-six surveys were returned (51.5 % response rate). When asked about the practice's team-based functioning, 8 % of the residents were very satisfied, 42 % were somewhat satisfied, 42 % were somewhat dissatisfied, and 8 % were very dissatisfied. Levels of satisfaction (somewhat satisfied) for components of team-based care, such as co-management of patients' medical conditions, communication about patient care, shared responsibility of patient care, and personal support from team members, ranged from 37 to 48 %. Six-month follow-up survey results are pending. The regular meeting schedule was maintained without disruption of clinical care, losses in productivity, or significant use of additional funding sources.

DISCUSSION/REFLECTION/LESSONS LEARNED: Weekly interdisciplinary team meetings are a feasible method of introducing internal medicine residents to team-based care in an ambulatory setting. Ongoing evaluation will determine whether participation in such meetings alters attitudes toward team-based care. The role of team meetings in influencing ACGME core competencies or other performance metrics requires further study.

TEACHING THE PATIENT-CENTERED MEDICAL HOME Elisha L. Brownfield; Benjamin Clyburn; Kimberly S. Davis; William P. Moran; Patrick D. Mauldin. MUSC, Charleston, SC. (*Tracking ID #1936971*)

NEEDS AND OBJECTIVES: The consensus report from the Alliance for Academic Internal Medicine Education Redesign Task Force calls for transformative ambulatory training for Internal Medicine. This would include the training of residents in highly functional ambulatory care settings and allowing residents to take on leadership roles within multidisciplinary clinical care teams while minimizing the conflict between outpatient and inpatient responsibilities. To date, there are few published educational models for Internal Medicine residency programs. In July 2012, our Internal Medicine (IM) residency program redesigned ambulatory training. Our objectives included: 1) improvement of care continuity, 2) increased exposure to common outpatient clinical problems and non-Internal Medicine specialties, 3) expansion of the ambulatory curriculum, 4) separation of inpatient and outpatient responsibilities, and 4) improved resident satisfaction of the clinic experience.

SETTING AND PARTICIPANTS: The University Internal Medicine (UIM) is a hospital-based, General Internal Medicine teaching clinic with approximately 11,000 patients and an NCQA-certified Level 3 Patient Centered Medical Home. Since July 2012, a total of 92 categorical Internal Medicine and combined (Med-Peds and Med-Psych) PGY 2–3 residents have rotated through the new ambulatory curriculum. The UIM is staffed by 15 Internal Medicine faculty members and a complement of registered and licensed practical nurses, certified medical assistants, PharmD/certified diabetes educators, social worker, and administrative support staff.

DESCRIPTION: In July 2012, the IM program transitioned all of its PGY 2–3 categorical residents from a weekly half-day clinic schedule into a monthly clinic block occurring every 4th month throughout the year. During these blocks, residents have no ward responsibilities and spend 6–7 half days per week in the UIM clinic while the remainder of the week rotate through a variety of other experiences including gynecology, dermatology, orthopedics, otolaryngology, allergy and sleep medicine. Each resident also has an assigned academic half day during the week. Residents are grouped into teams of approximately 15 residents all sharing the same nurse case manager. Significant curriculum changes include enhanced didactic conferences and required completion of an online curriculum and mini-CEX evaluations. A weekly interdisciplinary meeting focusing on systems-based care of resident panel patients was introduced and most recently centers on patients with poorly controlled diabetes and hypertension.

EVALUATION: Cumulative resident evaluation scores for the UIM rotation were comparable between pre-intervention and post-intervention time periods (1207 responses: 3.47, 102 responses: 3.50 Likert scale 1–4). In a May 2013 survey of 28 residents, the majority felt the interdisciplinary meeting lead to improvements in clinic operations (57.1 % "strongly agree/agree"). These residents were less sure of their own roles within the PCMH (46.4 % "strongly agree/agree"; 39.3 % "disagree/strongly disagree") or the roles of team members (32.1 % "strongly agree/agree", 57.1 % "disagree/strongly disagree"). Follow-up surveys are pending. Resident

continuity rates for 6788 visits (Oct 2012–Jan 2013) were 45 % for individual Primary Care Physician and 88–89 % for patient care teams. No pre-intervention comparison is available, and published rates are rare, but generally are below 50 %. Although not an explicit goal of the curricular change, there is an upward trend ambulatory medicine career choice (average 2004–2013: 4, 2014: 6).

DISCUSSION/REFLECTION/LESSONS LEARNED: Our categorical Internal Medicine residents now experience complete separation of inpatient and outpatient responsibilities and an enhanced PCMH curriculum. Patient panel audits are provided to each resident, and the completion of an online curriculum and mini-CEX requirements are ensured. As our program transitions to ACGME milestone reporting, the ambulatory rotation provided early experience with this new requirement. Patient continuity within resident teams is high, but remains <50 % per individual resident. Overall, resident satisfaction with their outpatient experience is high. Strengths of the new program include: the ability to train residents within a certified PCMH, resident reflection of a patient-care data audit involving an interdisciplinary team, experience with other related specialties, and an excellent opportunity to evaluate residents over time. Our greatest challenges continue to be an increase in the administrative and teaching burden for faculty and staff, clinic staff shortages and turnover, cultural shift changes for all working in the PCMH, patient care continuity in the resident panels, and data management needs for our population management.

THE (ELECTRONIC) CHART WAR: RESIDENT AND FACULTY PERCEPTIONS AND PRACTICES IN OUTPATIENT DOCUMENTATION AND CHART MANAGEMENT Sarah A. Tilstra; Peggy Hasley; Anu Munshi; Brian S. Heist; Shanta M. Zimmer; Jaishree Hariharan. University of Pittsburgh Medical Center, Pittsburgh, PA. (*Tracking ID #1939144*)

NEEDS AND OBJECTIVES: The electronic health record (EHR) has simplified communication among providers and improved clinical decision support while creating complexity in documentation for medical trainees to master. There is no consensus on how to best teach outpatient documentation and chart management to residents. Last year, we reported on current resident practices in outpatient documentation which confirmed that residents excel in documentation within the progress note but routinely fail to update the overall EHR portal. This can impact quality, medical errors, communication with providers, efficiency, and reimbursement. Thus, an ideal resident curriculum should not just focus on the appropriate components of a progress note but also on how to best navigate, update, and utilize the online patient portal. We set out to define residents' and faculty opinions regarding outpatient chart management by surveying our current residents and teaching faculty. Our objectives are: 1. Determine the perceived efficiency and accuracy of outpatient clinical documentation 2. Describe the barriers to effective documentation 3. Identify curricular needs for an outpatient resident documentation/chart management

SETTING AND PARTICIPANTS: Two faculty/resident clinic sites at the University of Pittsburgh Medical Center where 72 categorical residents and precepting faculty hold their weekly continuity clinic. Both practices have a fully integrated EHR (EpicCare).

DESCRIPTION: Individual surveys for teaching faculty and residents were designed by the curricular team. Twenty-one questions were exactly the same, but appropriately worded for residents or faculty. Two additional questions were included in the faculty survey. Surveys were vetted for clarity and appropriateness by the residency program administration and faculty leadership prior to distribution in May 2013 via Survey Monkey.

EVALUATION: Overall, 39/72 (54 %) residents and 14/19 (74 %) eligible teaching faculty completed surveys. Only 39 % percent of residents report satisfaction with their training in outpatient documentation and chart management, 21 % received formal training in medical school, while 57 % of faculty received training during their career. When compared to faculty, residents have a harder time completing outpatient notes within 24 h (100 % vs. 87 %), are less confident knowing the required documentation elements for a given clinical encounter (86 % vs. 56 %), are less comfortable determining the appropriate billing for a patient encounter (100 % vs. 44 %), are less likely to know how their "quality of care" is measured (93 % vs. 61 %), are more likely to cut-and-paste from their last note (7 % vs. 13 %), and less likely to use templates for documentation (67 % vs. 54 %). Sixty-two percent of residents, compared to 7 % of faculty, report spending >20 min on documentation per patient encounter, with 50 % of these encounters taking more than 25 min per patient. Faculty and residents are equally comfortable using the electronic "tabs" within the EHR, but faculty more often update the tabs to reflect appropriate clinical information. Eighty-six percent of faculty members have received feedback on

documentation whereas only 54 % of residents routinely receive feedback. Preceptors routinely give residents feedback 43 % of the time, but do review and make changes to the documentation without giving direct feedback 79 % of the time. Residents mostly “struggle” with completing documentation on time. Knowing what to include in a note for specific patient encounters was second, followed by identifying appropriate billing and updating the tabs in the electronic chart. Nearly 50 % of residents identified “more training” in the electronic chart with “frequent refreshers” as a mandatory step in moving forward, with a subset of residents asking for “easier to use templates” to streamline documentation. Faculty also reported that “time” was a major struggle in completing outpatient documentation and that better templates could make this easier. Training in “billing requirements” and “electronic-portal maintenance” should be vital components in the outpatient curriculum.

DISCUSSION/REFLECTION/LESSONS LEARNED: Residents are not well trained in outpatient documentation and electronic chart management, and struggle with efficiency, navigating/updating the electronic portal, identifying needed components for documentation and billing, and do not receive adequate feedback. Going forward, we plan to develop a longitudinal outpatient documentation and chart management curriculum using “minimum standards” that are tailored to each PGY level, develop easy-to-use templates, construct an objective chart evaluation tool, and outline regular feedback intervals for residents.

THE EFFECT OF GENDER ON ATTITUDES TOWARD THE HOMELESS AMONG PRIMARY CARE INTERNAL MEDICINE RESIDENTS Frances Norlock; Laura Sadowski; Meghan Kapolnek. Stroger Hospital of Cook County, Chicago, IL. (*Tracking ID #1938650*)

NEEDS AND OBJECTIVES: The prevalence of homelessness is increasing. Few resident programs offer formal training in how to provide care for the homeless. Educators implemented a homeless medicine rotation to decrease residents’ stigma associated with homelessness and improve the clinical care they provide to homeless patients. Investigators hypothesized that resident gender would affect one’s attitude toward the homeless in that female residents would have lower stigma than their male counterparts prior to the educational intervention, and in turn, male residents would have greater improvement of their stigma scores than female residents by the end of the rotation.

SETTING AND PARTICIPANTS: PCIM residents ($n=12$) participated in a 2 week homeless medicine rotation based at an urban, public hospital focused on collaborating with partners in the community. Residents participated in group seminars on campus, engaged in tours and clinical experiences in the community including working with patients in shelters, clinics and residential housing programs.

DESCRIPTION: Curriculum consisted of small group seminars on the epidemiology, chronic disease management, health outcomes, and lifestyle issues affecting morbidity and mortality in this population. Residents worked in community-based clinics that served the homeless including those with addictions and the recently incarcerated. Learners were assigned evening shifts to care for those in shelters with medical issues as well as residential facilities which cared for women and children. Residents also heard life stories from homeless individuals in small group settings. Residents’ attitudes were assessed before and after the course through an 11 item Attitudes Toward Homelessness Inventory (ATHI) consisting of 4 subscales which attribute homelessness to societal cause; personal cause; having a willingness to affiliate with the homeless; and belief that homelessness is a solvable problem. A higher summation score of the 4 subscales equates to a lower stigmatizing attitude of homelessness. A meaningful difference score of 5.5 was set a priori.

EVALUATION: Results from the ATHI showed that women did have lower levels of stigma toward the homeless at the onset of the rotation with a higher total summation score of 45.5 compared to the male summation score of 38.5 (p-value 0.14) consistent with a meaningful difference in gender prior to the rotation. The improvement in total scores overall was 1.75 among women and 7.6 points among men consistent with a meaningful change in scores between men and women (5.85 points), and a meaningful change in score for male residents (7.6 points) post-rotation. The greatest mean change in score between men and women was an improvement of 2.6 points in the personal cause subscale. Lastly, women had lower stigma scores for all 4 subscales pre- and post-rotation with the greatest improvement of 2.5 points in the societal cause score.

DISCUSSION/REFLECTION/LESSONS LEARNED: Educators showed higher stigmatizing attitudes toward the homeless associated with gender, but with a dedicated homeless medicine rotation male residents did have a meaningful improvement in their attitudes by the end of the rotation with the greatest improvement in the personal cause subscale. Findings suggest the need for residents

to be trained in caring for the homeless to improve attitudes and lower stigma when caring for this vulnerable population.

THE NEW KID ON THE BLOCK: TEAM BASED LEARNING CURRICULUM IN AMBULATORY EDUCATION, A PROMISING ALTERNATIVE Raghav Sharma; Sandy Balwan; Alice Fornari; Tomoko Ouchi. North Shore LIJ Health System, Great Neck, NY. (*Tracking ID #1938778*)

NEEDS AND OBJECTIVES: Team Based Learning (TBL) was developed to promote active learning, problem solving, and concept application in college classrooms and is a key strategy in undergraduate medical education. Compared to didactic teaching, TBL provides an active learning strategy that strongly engages participants in the learning process. There is little data however, on the use of TBL in Graduate Medical Education (GME). In 2012, we replaced our didactic based ambulatory medicine curriculum with a TBL curriculum. We hypothesized that residents would report better engagement and that faculty would report more resident involvement. We also hypothesized that residents’ medical knowledge would improve based on their in-training exam scores.

SETTING AND PARTICIPANTS: All ambulatory clinic sites of a large urban internal medicine residency program participated. Each site hosted 12 residents for 35 weeks. A total of 258 Resident surveys and 34 faculty surveys were reviewed.

DESCRIPTION: Residents were divided into two groups prior to initiating TBL sessions. Ambulatory faculty members prepared 7 distinct TBL modules: Diabetes, hypertension, hyperlipidemia, perioperative evaluation, asthma, dizziness, and GERD. TBL sessions were held for 1 h, 3 days per week. At the beginning of the TBL sessions, residents underwent a closed book quiz on a previously emailed article, followed by a group quiz, and concluded with a group discussion of the answers. During the second session residents received a clinical vignette on which they self assigned learning objectives (LO), which were discussed in a round table fashion at the close of the week’s TBL session. At the conclusion of the TBL sessions residents were given anonymous peer evaluations and separate surveys assessing peer performance, self-engagement, and faculty member facilitation. The faculty and residents received 10 and 12 survey questions respectively. Responses were measured on a 5-point Likert scale. The results account for the mean of the numeric value of each question. The assessment of medical knowledge of the residents is ongoing, pending the results of the in-service exam scores.

EVALUATION: Most residents and faculty agreed to strongly agreed that co-residents and themselves were actively involved in the TBL session and contributed meaningfully to the discussion. Residents and faculty further responded that residents were paying attention most of the time to the TBL session and residents were active learners during discussions. Residents agreed that they would like more TBL sessions and found the faculty members to be effective facilitators. Residents neither agreed nor disagreed whether the facilitator assumed a lecture model.

DISCUSSION/REFLECTION/LESSONS LEARNED: The Integration of TBL into ambulatory residency curriculum fosters proactive resident engagement and personal accountability of the learner, leading to a more dynamic learning environment and enhanced retention. However, mild barriers remain as facilitators may default to traditional teaching styles while adjusting to a TBL based curriculum. Overall, if appropriately implemented in an ambulatory setting, TBL would help enrich the teaching and learning climate in residency programs throughout the country.

THE RESIDENT AS TEACHER: IMPLEMENTATION OF AN EVIDENCE-BASED, BEST-PRACTICES APPROACH TO CLINICAL EDUCATION THROUGH A TEACHING ELECTIVE FOR RESIDENTS Bret Simon¹; Christopher Moreland^{1,2}; Kanapa Komsawad^{1,2}. ¹Univ Texas Health Science Center San Antonio, San Antonio, TX; ²South Texas Veterans Health Care System, San Antonio, TX. (*Tracking ID #1940759*)

NEEDS AND OBJECTIVES: Residents make essential contributions to medical education through their work with fellow residents and medical students. However, like many faculty, residents typically have little to no formal training in educational principles and practices. The “clinical-educator” is typically more clinician than educator. In an effort to improve educational practices generally, and to introduce trainees to current research and practice in clinical teaching, we designed and implemented a one-month elective rotation on “The Resident as Teacher.”

SETTING AND PARTICIPANTS: The course is open to R2 and R3 residents at a large teaching hospital in the south central US. Offered all months except December, and open to no more than two residents per rotation.

DESCRIPTION: The rotation is founded on core tenets of adult learning theory (Knowles) and stresses autonomy, self-identification of learning goals, collaboration in identifying methods of achieving self-identified learning goals, and self-evaluation of progress toward those goals. Reflective writing is a major component of the rotation, as residents are asked to respond in writing to 12–15 current readings from the professional literature. We believe that this practice of “writing to learn” is underutilized in medical education and represents a significant source of learning in this course. Residents also participate in facilitated or guided activity during the rotation through teaching activity, shadowing teams during rounds, giving feedback to students, and observing other educational practices. Readings are selected to parallel resident goals, and reflections are a way to integrate knowledge and direct experience in the teaching activities. A critical component of the course is weekly meetings between residents and course directors. These loosely structured, collegial discussions are a way of promoting critical thinking and self-insight in learners.

EVALUATION: One of the novel aspects of this course is the use of concept mapping as a method of learner evaluation. Residents are provided with resources and examples at the beginning of the rotation and told they will be asked to illustrate the process of clinical teaching via a concept map by the end of the course. Residents share their current concepts and connections during weekly meetings and share their current concept map with course directors. This process encourages deep-learning and the integration of principles and practices. It requires analysis and synthesis—higher order cognitive processes—and helps assure long-term retention and use of content.

DISCUSSION/REFLECTION/LESSONS LEARNED: Residents come to this rotation with a variety of teaching experiences, but the content and methods in this course are clearly new to all residents to date. The course is scholarly in nature, relying heavily on the professional literature and not simply a “how-to” approach to clinical teaching. This practice mirrors the evidence-based approach to medicine advocated in clinical practice, as one of our goals is to help learners recognize that there is body of evidence relevant to teaching as well. We have been somewhat surprised at the learning goals identified by residents, as the same goals are frequently reported: feedback skills, motivating learners, teaching styles, and being a better presenter. The utility of the concept map as a method of self-assessment and summative evaluation has been less clear. We find that some residents enjoy the activity, but many are also perplexed by it. By limiting ourselves to this visual form of organization and synthesis, we may fail to recognize the range of learning approaches residents may take. Thus, we are currently considering other synthetic activities—narrative, checklists—as alternative demonstrations of competence.

THE USE OF SOCIAL MEDIA TO SUPPLEMENT RESIDENT MEDICAL EDUCATION Panagis Galiatsatos; Fernanda Porto Carreiro; Jennifer Hayashi; Sammy Zakaria; Colleen Christmas. Johns Hopkins Bayview Medical Center, Baltimore, MD. (Tracking ID #1928160)

NEEDS AND OBJECTIVES: Since residents work at variable times, new approaches to asynchronous learning are needed to ensure all residents receive a comprehensive education. The use of social media tools may be useful, because they can be accessed at a time convenient to the learner. The objective of this study is to assess if the use of Twitter for medical education impacts the attitude and behavior of physicians-in-training towards using social media for medical education.

SETTING AND PARTICIPANTS: Pre-intervention and post-intervention surveys. Internal medicine resident physicians were surveyed before the launching of the “Hopkins Bayview IM” Twitter page on August 1, 2013, and again 135 days later, to determine their use of the twitter application, web page, and social media for medical education in general. Participants included residents at an internal medicine urban academic training program.

DESCRIPTION: All residents within our training program were administered web-based surveys, immediately before and then 135 days after creating a Twitter page devoted to medical education. The surveys assessed views and frequency of use of social media for medical education purposes, and consisted of ten Likert scale questions. Each answer consisted of a data-point on a 1–5 scale (1 = not useful, 3 = useful, 5 = very useful). The final question was open ended, and asked for general comments.

EVALUATION: Thirty-five of 50 residents (70 %) completed the pre-survey and 37 (74 %) participated in the post-survey. At baseline, 34 out of 35 residents used social media and 9 used Twitter specifically. However, only 22 (63 %) used social media for medical education, and 3 specifically used Twitter. After the establishment of the Twitter page, the percentage of residents using social media for educational purposes increased (31 of 37 residents, 84 %), 22 specifically used Twitter ($p=0.03$ for the change), and their frequency of using the application at least once a week increased

from 11.5 to 56.8 % ($p<0.05$). Almost all residents (35 of 37) felt that social media could be useful as a medical education tool, which numerically increased from 29 out of 35 in the pre-intervention survey, but these percentages were not statistically significant ($p=0.37$).

DISCUSSION/REFLECTION/LESSONS LEARNED: Residents believe social media could be used for medical education. After we launched a Twitter page for medical education, there was a significant increase in the use and frequency of Twitter for resident medical education. Further research should be performed to see if social media can impact overall medical knowledge and patient care.

USING A WEB LOG TO ENHANCE COMPETENCY IN MEDICAL KNOWLEDGE AND PRACTICE BASED LEARNING AND IMPROVEMENT Matthew Hollon. Sacred Heart Medical Center, Spokane, WA. (Tracking ID #1940872)

NEEDS AND OBJECTIVES: Literature suggests that role modeling is a nuanced, deliberate learning strategy. We postulated that faculty transparency in how we learn from uncertainty in our everyday clinical work would lead residents to embrace and incorporate the core principles of the competency of “Practice Based Learning and Improvement” (PBLI) into their professional development. The faculty sought to model the steps of PBLI on a weekly basis through the use of a web log or “blog” by posting a clinical scenario where we were faced with uncertainty about the best way to proceed then translated that into a clinical question and pursued an answer. Simultaneously, we sought to share our acquired medical knowledge with our whole program through the blog.

SETTING AND PARTICIPANTS: A community-based, university-affiliated internal medicine residency program with a total of 21 residents and 8 core faculty.

DESCRIPTION: Prior to the start of the project, we surveyed residents about actions consistent with the fundamental steps of PBLI. Specifically we asked residents the frequency that they felt uncertain in clinical situations over the last month, how often they searched for answers when faced with uncertainty, and how often they successfully found answers. Subsequently, once each week for a period of 24 weeks, 1 of 8 core faculty members wrote a summary of a situation where he or she faced clinical uncertainty, a description of how he or she went about finding an answer, and a discussion of the medical knowledge learned. Prior to the summary being posted to the blog and accessible to everyone in the program, we distributed electronically a single pre-test question to assess baseline knowledge in the area covered by the summary. One week following distribution of the pre-test, we closed access to the question then posted the written summary. Approximately 1 month after the end of this 6 month project, we distributed a final survey. This survey reassessed medical knowledge of topics covered in the faculty posts using the same 24 single pretest questions. The survey also re-evaluated actions consistent with the PBLI steps.

EVALUATION: All residents completed both the initial and final survey and completed, on average, 77 % of the single pretest knowledge questions. The frequency that residents encountered clinical situations where they felt uncertain declined over the course of the 24 weeks from a mean frequency of uncertainty of 36 % to 28 % ($p=0.008$). The frequency with which residents sought answers when faced with uncertainty prior to the project was high at mean of 81 % and had not changed significantly 24 weeks later remaining at a mean of 78 %. The range of the frequency of answer seeking when faced with uncertainty was between 30 % and 100 % with a total of 3 residents reporting on the final survey that they sought answers less than half the time when faced with uncertainty while 15 residents sought answers at least 80 % of the time. Success in finding an answer to questions generated by clinical uncertainty did not change significantly from before to after the project, remaining at a mean of approximately 75 %. Medical knowledge improved significantly ($p=0.001$) with the use of faculty posts to the blog. Prior to posting answers to clinical questions, residents got a mean of 52 % of knowledge questions correct. When reassessed 1 month after the end of the 6 month period, residents got a mean of 65 % of questions these correct. Lastly, 95 % of residents felt that faculty should continue to post general clinical content to the blog.

DISCUSSION/REFLECTION/LESSONS LEARNED: We noticed a slight decline in clinical uncertainty over the course of 6 months consistent with expectations. However, we failed to show improvement in frequency of searching for answers when faced with uncertainty. Notably, this is already happening at high level for most, which is reassuring, making it difficult to show large improvement. We did note that some residents were less engaged in the fundamentals of PBLI. It may be that efforts to encourage self-reflection, recognition of clinical uncertainty, and answer seeking are best targeted to this group. Interestingly, strategies for finding answers did not seem to change substantially. Despite faculty role modeling using primary data found

through PubMed searches, residents continued to most frequently use general resources when seeking answers to clinical questions. We did demonstrate that faculty posting to a blog led to modest improvements in medical knowledge. This was particularly noteworthy given that retest occurred up to 7 months after the initial posts of answers. Finally, residents truly appreciated this intervention. As the blog became increasingly valued as a resource for clinical information, it even inspired some residents to do their own posting of medical knowledge content. In summary, faculty role modeling of PBL through a blog was valued by residents and led to modest improvements in medical knowledge but did not alter behavior that was already taking place frequently.

USING COLLABORATIVE EVALUATION TO IDENTIFY CRITERIA FOR THE ASSESSMENT OF ATTENDING PHYSICIANS IN HOSPITAL MEDICINE Bret Simon¹; Luci Leykum^{1,2}; Jane E. O'Rorke^{1,2}; Megan Freeman¹. ¹Univ Texas Health Science Center San Antonio, San Antonio, TX; ²South Texas Veterans Health Care System, San Antonio, TX. (*Tracking ID #1940677*)

NEEDS AND OBJECTIVES: Various approaches to the assessment of attending physicians have been reported in the literature. Externally determined criteria (e.g., ACGME, ABIM) are often used to ensure that measures required for accreditation are addressed. Such tools are useful for making comparisons across institutions, but they may fail to identify institution-specific needs. These measures may be particularly inadequate in cases where rapid curricular changes are being implemented or professional development activity results in extensive and significant changes in the way attendings and residents interact. Nominal Group Technique can be used as a means of identifying institution-, program-, or specialty-specific evaluation issues that are particularly salient or newly emergent. We sought to use NGT as a method for obtaining stakeholder input on attending performance in the inpatient general medicine setting.

SETTING AND PARTICIPANTS: Two teaching hospitals (community and Veteran's Administration) serving as primary training sites for a large medical school in the south central US. Participants included three categories of stakeholders whose roles were principally in medical education in the inpatient setting. The three groups included hospitalist faculty, administrators (departmental, hospital, and graduate medical education), and residents representing all 3 years of training. A total of 24 individuals participated.

DESCRIPTION: The Nominal Group Technique is designed to solicit input around a particular problem, issue, or concern from a range of stakeholders. The process is transparent—a feature particularly important when participants represent a range of organizational levels (dean, faculty, resident). Participants offer their input as short phrases or words in response to a central question, written on white-boards so they are viewable by all participants. In this case, “What criteria should be used by housestaff to assess attending performance?” The method is a three-step process: 1) solicitation of input from participants in an unedited, round-robin fashion until all views are expressed, 2) group review of the content to consider consolidation or elimination of content that is duplicative, 3) individual ranking of the final list of words or phrases. The ranking process can vary, but in this case participants were asked to identify their top five items. Points were assigned according to rank, with five points assigned to the top rank and one point assigned to the lowest rank. The final product is a list of rank-ordered items, produced by all stakeholders, to address the question posed.

EVALUATION: Participants identified nearly 90 items related to the evaluation of attending performance. After some consolidation, 12 items were eliminated. Despite the large number of items, when they were summed and ranked, only 11 were scored high enough, or were selected by enough participants, to achieve a score of more than 10 points. These items served as the core content for a review and modification of the existing attending evaluation form. Items included: professionalism; clinical knowledge; organized approach to teaching; provides useful, timely, formative and summative, written and oral feedback; clear expectations of all team members; communication skills; ability to convey thought process; ability to provide proper autonomy and supervision; interpersonal skills with learners, patients, and families; quality of teaching; and promotes critical thinking.

DISCUSSION/REFLECTION/LESSONS LEARNED: We found that many of the items identified as important criteria for the assessment of attending performance were already, to some degree, part of the existing evaluation form. Nonetheless, we have been able to utilize the input of our stakeholders to help clarify and operationalize behaviors associated with broad concepts like professionalism and communication skills. Our intent is to continue to use the nominal group technique on a semi-annual basis to assure that our attending evaluation process is adequately representing the needs and concerns of stakeholders.

USING HUDDLES TO INTEGRATE MEDICAL RESIDENTS INTO AMBULATORY TEAMS Joshua M. Liao; Andrew J. Van Wieren; Brigid M. Dolan. Brigham & Women's Hospital/Harvard Medical School, Boston, MA. (*Tracking ID #1927565*)

NEEDS AND OBJECTIVES: Harvard Medical School's Center for Primary Care recently launched the Academic Innovations Collaborative to catalyze widespread innovation and transformation at affiliated primary care clinics. While the initiative requires participating sites to focus on team-based care and incorporate trainees into them, many sites have found it difficult to integrate medical residents - frontline physicians and large portions of the clinical workforce - into care teams.

SETTING AND PARTICIPANTS: Recognizing the importance of resident involvement in team-based care, we selected an affiliated community health center in Southern Jamaica Plain staffed by practicing primary care providers, a cohort of full-time MAs, and resident physicians from the Brigham & Women's Hospital Internal Medicine Residency. We chose the site because of strong leadership support for this work, low turnover rate among its MAs, and the presence of large proportions of full-time providers with prior experience in huddling with MAs.

DESCRIPTION: We framed our project within the period when residents were physically at their half-day continuity clinic sessions. We incorporated Lean principles to study existing processes and root causes by observing in-clinic communication between physicians - both full-time and resident physicians - and medical assistants (MAs). Based on our mapping and analysis, we used an impact/effort matrix to evaluate and prioritize potential ideas, ultimately deciding on resident-MA huddles as a high yield intervention. We utilized a Plan-Do-Study-Act approach to implement pre- and post-clinic resident-MA huddles. These were initially done under the supervision and guidance of experienced physician preceptors, but eventually residents and MAs ran independent huddles. We collected pre- and post-intervention surveys from practicing physician preceptors, residents and MAs assessing their perceptions of resident integration into care teams.

EVALUATION: Using verbal feedback and written post-intervention surveys, we gathered data on process measures (adherence to huddles) and outcome measures (effect on perceptions of resident integration into care teams). The frequency of both pre- and post-clinic huddles increased over our study period. Our work revealed that while pre-clinic huddles were relatively easy to adopt, post-clinic huddles were considerably more difficult to organize. Interestingly, resident physicians and physician preceptors perceived residents as becoming more integrated into care teams over the study period. In contrast, MAs felt that resident integration did not change significantly. This was in part due to their perception that despite huddles, residents still spent very limited time in the clinic. Another important issue was that MAs felt that while full-time clinic physicians were able to communicate plans iteratively with staff, there was frequently no formal communication plan established between residents and MAs.

DISCUSSION/REFLECTION/LESSONS LEARNED: This project taught us several important lessons. First, it supported the idea that huddles can be used effectively to increase perceptions of resident integration into clinic teams. However, it also revealed that these perceptions can vary based on an individual's role on the clinical team. These two findings underscore the reality that teamwork is based on more than just the execution of pre- and post-clinic communication. Perhaps not surprisingly, they show that the content and format of communication is important. They reveal that how and when information is communicated may be more crucial for building a sense of team than the act and consistency of communication. Our data also suggests that to clinic staff, the activities that occur outside of clinic sessions may also contribute significantly to perceptions of resident integration. The ability for staff to interact with full-time physicians iteratively throughout full workdays may be important for clarifying plans, improving communication, building relationships, and contributing to a sense of team integration. Because in contrast, huddles only add an additional few minutes to a resident's total time in clinic, staff may perceive them to be less integrated even despite huddles. Going forward, educational changes such as the ambulatory “burst” model will likely increase the amount of contiguous clinic time, and thereby increase the chance that residents can interact iteratively and naturally with MAs like full-time practitioners frequently do. Regardless, huddles will still play important roles in sustaining communication between resident physicians and clinic staff. We plan to maximize adherence to and impact of resident-MA huddles by adjusting our huddle format, ensuring that individuals convey content that is important to team workflow, and developing this into even more of a joint effort among all clinic staff via dashboards in staff meetings and reports of current huddle rates and resident integration scores. We are also exploring expansion of this project to other clinic sites.

UTHSCSA SAFE SPACE: BECOMING AN ALLY TO THE LGBTQ COMMUNITIES Christopher A. Alonzo, UTHSCSA, San Antonio, TX. (*Tracking ID #1937061*)

NEEDS AND OBJECTIVES: Healthy People 2020 acknowledges a need to address the health disparities endured by many lesbian, gay, bisexual, transgender, and queer/questioning (LGBTQ) individuals. Such disparities are rooted in discrimination, violence, civil rights inequalities, and poor access to health care. Sequeira et al. (2013) noted: "The Institute of Medicine recognizes that few practicing physicians are knowledgeable about and sensitive to the needs of LGBT patients. A recent survey of medical school deans found that medical school curricula devote a median of 5 h covering LGBT-related content across the 4-year curriculum. The same group indicated that improving access to curricular material would be the best way to increase the amount of content presented on this subject." The need for increased LGBTQ knowledge is clear, and it is necessary that individuals in an academic medical setting learn about health disparities endured by many lesbian, gay, bisexual, transgender, and queer/questioning (LGBTQ) individuals. The Safe Space program aims to correct this lack of knowledge as well as aims to identify the LGBTQ population and their perceptions of the healthcare communities' knowledge base. This interactive presentation will provide an educational resource for colleagues and future healthcare professionals about this important topic and methods to evaluate its effectiveness. Objectives 1. Discuss how the UTHSCSA Safe Space is educating students, faculty, staff, and clinicians about social, environmental, and physical factors that influence the health of lesbian, gay, bisexual, transgender, and queer (LGBTQ) individuals. 2. Describe Safe Space outcomes to date 3. Discuss Survey model for identifying LGBTQ community demographics and opinions.

SETTING AND PARTICIPANTS: The UT Health Science Center Safe Space program is designed to raise cultural competency and professionalism of all students, faculty, and staff at the Health Science Center to include more knowledge of the LGBTQ population.

DESCRIPTION: Participants in the program undergo one lecture workshop approximately 90 min in length. The lecture and discussions provide information on the following topics: knowledge of LGBT terminology, stereotypes, the coming out process, suicide risk, knowledge of bias, LGBTQ education, LGBTQ resources, Suicide prevention resources, and preparedness for dealing with LGBTQ issues or scenarios. Workshops include opportunities for participants to open a dialogue on topics such as conflict management, employment regulations, adoption practices locally and nationally, substance abuse, suicide, depression and transitions between genders, all concerning LGBTQ persons. Safe Space participants are required to complete a pre and post-training survey that assesses baseline knowledge of LGBTQ terminology, the coming out experience, and suicide resources. The LGBT Access to healthcare survey will provide information about the Rio Grande Valleys LGBTQ communities and their access to healthcare in the valley. The survey aims to sample a population of the LGBTQ population in the Rio Grande Valley, the presence of supportive populations, the level of comfort when accessing healthcare in the Rio Grande Valley, the perception of bias from healthcare personal in providing treatment, and the perception of the LGBTQ population on the education status of healthcare workers on LGBT topics. The survey will be anonymous. A copy of the LGBTQ community surveys will also be distributed to the attendees for their review and comments.

EVALUATION: Analysis following a two tailed *T*-test showed significant improvements in knowledge of LGBT and Suicide resources, the coming out process, suicide risk assessment and most importantly feeling prepared with dealing with LGBT issues.

DISCUSSION/REFLECTION/LESSONS LEARNED: The UT Health Science Center Safe Space Program met with a great amount of success during its initial implementation between 2012 and 2013. The data showed significance in increasing the fund of knowledge of students faculty and in regards to certain topics discussed. Some major feedback that is provided is that participants would like longer sessions to increase discussion times, as well as have more members of the LGBTQ community present to aid in the presentation. The topic is a rapidly developing field and would do well to establish itself as a permanent area of medical education.

VHA'S COMPREHENSIVE WOMEN'S HEALTH SCAN-ECHO PROGRAM: LESSONS LEARNED

Kristina M. Cordasco^{1,3}; Jessica Zuchowski¹; Alison B. Hamilton^{1,4}; Herschel Knapp²; Joann O. Saavedra²; Donna L. Washington^{1,3}. ¹VA Greater Los Angeles Healthcare System, North Hills, CA; ²VA Greater Los Angeles Healthcare System, Los Angeles, CA; ³The University of California, Los Angeles, Los Angeles, CA; ⁴The University of California, Los Angeles, Los Angeles, CA. (*Tracking ID #1939313*)

NEEDS AND OBJECTIVES: Although women are among the fastest growing segment of the Veterans' Health Administration (VHA) patient population, many VHA primary care providers' (PCPs) have relatively small female caseloads, making it challenging for them to build and maintain their women's health knowledge and skills. Therefore, as part of VA's SCAN-ECHO (Specialty Care Access Network - Extension for Community Healthcare Outcomes) program, we implemented a Comprehensive Women's Health SCAN-ECHO program with the objective of building and maintaining VHA women's health PCPs' knowledge in the evaluation and management of conditions specific to, more common in, or with special considerations relevant to women (e.g., gynecology, breast issues, depression, osteoporosis).

SETTING AND PARTICIPANTS: Our participants included women's health PCPs across three VHA healthcare systems.

DESCRIPTION: The program consisted of monthly group PCP-specialist clinical tele-videoconferencing sessions in which PCPs obtained virtual specialist consultation on their cases and received serial patient-based education. Prior to each session, PCPs submitted consultation requests on patients for whom they wanted diagnostic and/or therapeutic management advice. During sessions, the specialists at a "hub" facility and PCPs at multiple "spoke" sites engaged in real-time group discussions about the cases. In addition to giving recommendations, the specialist discussed the underlying evidence or rationale. Content also included patient communication strategies (e.g., explaining contraceptive options). The PCP who submitted the consult, as well as other PCPs participating in the session, interacted with the specialist and with each other, asking clarifying questions. The specialist also provided a brief didactic relevant to the cases. Continuing Medical Education credit was provided. Each session was held at the noon hour in the hosting site's time zone.

EVALUATION: We used participation logs, participant surveys, semi-structured interviews, and field notes from key stakeholder meetings to evaluate our program. We conducted 14 sessions over 16 months. Overall, 65 PCPs in three VHA health care systems participated in one or more sessions, with an average of 11 participants per session. Participation rates were much higher in the one healthcare system where providers were provided with time protected from their clinic responsibilities (rather than meeting over lunch). Attempts to expand to two additional VHA healthcare systems, where the session would have been in the lunch hour, were not successful secondary to conflicting meetings or educational programming. Of the 58 post-session surveys received, in 45 (78 %) the participant strongly agreed, and in 7 (12 %) the participant agreed, that the information provided in the session would influence their patient care. Of these 52, 74 % indicated that the information would change their ordering of diagnostic studies; 83 % their treatment plans; 58 % their prescription of medications; and 68 % their overall interactions with patients. Among the 10 PCP interviewees, all reported that they found SCAN-ECHO to be useful for building and maintaining their knowledge on women's health topics. However, all interviewees also reported that the session being conducted during their lunch hour was a limiting factor for consistent participation, with morning clinics often running late and participants having competing clinical, administrative, educational and personal priorities for that time. Interviewees and discussions with key stakeholders revealed that the rotating specialists and topics across the breadth of women's health, although appealing in its comprehensiveness, also limited submission of cases as PCPs were unlikely to have active case-based questions coincident with the monthly specialist's area of expertise.

DISCUSSION/REFLECTION/LESSONS LEARNED: VA's SCAN-ECHO program is a promising modality for building and maintaining PCP knowledge on women's health topics, with attendees indicating that it influences their patient care. However, PCPs receiving time protected from clinical responsibilities is essential for robust and consistent participation. Further, narrowing in on a consistent women's health area, such as gynecology, although sacrificing the program's comprehensiveness, may facilitate PCPs having active case-based questions for the sessions.

VIDEOTAPING HOME VISITS—FIRST-YEAR MEDICAL STUDENTS BRING PATIENTS' WORLDS TO THE CLINICAL TEAM Barbara Ogur^{1,2}; Marie-Louise Jean-Baptiste¹; Jeremy Keller¹; Nancy Blum¹; Andreas Mitchell¹; Margaret Fallon¹; Elorm Avakame¹; Ethan Balgley¹; Betty Erfe¹; Grace Chao¹; Jose O. Gutierrez¹. ¹Harvard Medical School, Boston, MA; ²Harvard Medical School, Boston, MA. (*Tracking ID #1934147*)

NEEDS AND OBJECTIVES: Early exposure to patients is recognized as very valuable in providing students with opportunities to ground their scientific studies in clinical practice. According to learning theory and corroborated by observation, students learn more and feel motivated to learn more deeply when their learning is directly connected to real patients' experiences. Many programs begin clinical exposure in the first year, through a course in interviewing patients. These courses are highly valued by students. We describe a pilot to extend these curricula using the hypothesis that students will learn even more powerfully if their learning experiences provide them an opportunity to not just learn from patients but to actually contribute to their patient's care.

SETTING AND PARTICIPANTS: At Harvard Medical School, first year students have a year-long course in interviewing, Patient-Doctor 1, which emphasizes human connection and the understanding of patients' experiences of illness by providing students opportunities to interview patients and to reflect on their experiences in small groups with experienced clinician preceptors.

DESCRIPTION: We planned and implemented a pilot program to explore ways for first-year students to both learn from patients and also contribute meaningfully to patients' care. In one section of the course, as part of a required home visit, we asked one group of students, with written consent of their patients, to videotape the home environment. Students then provided their video and the written report of their home visit, including what special insights they learned about the patient from being in the home, to their patient's ambulatory clinical care team.

EVALUATION: We surveyed students, preceptors, and the clinical team caring for the patient to determine their feelings about this exercise. Samples of the videos will be available for review. Students reported that these home visits provided them with an expanded sense of the patient as a person with important connections to family and friends, with a role in the community, and with a coherent set of beliefs about health and diet perhaps not totally aligned with the beliefs of the medical world. Students found experiencing the physical adaptations for patients with mobility constraints very informative and directly witnessed possible environmental triggers for a patient with asthma. Clinical team members learned new information about patients' belief systems, adaptations, and social supports.

DISCUSSION/REFLECTION/LESSONS LEARNED: We piloted a small innovation of a medical school interviewing course that both provided students with a powerful learning experience in contextualizing patients' illnesses through the lens of patients' lives in their homes and communities and also through the lens of performing a valued function of bringing this broader view of the patient back to the clinical team. We believe this exercise warrants a trial with a larger cohort. We learned that students, preceptors, and clinical teams found the exercise useful and inspiring. We believe that first-year students can bring a valuable, humanizing perspective on the patient to over-stretched clinical teams as they also learn to be caring physicians attuned to their patients' real experiences.

VISUAL THINKING STRATEGIES: AN ARTS-BASED INTERVENTION TO TEACH TEAMWORK TO SENIOR MEDICAL STUDENTS Elizabeth Karwowski^{1,2}; Alexa R. Miller³; Suzanne Sarfaty¹. ¹Boston University Medical Center, Boston, MA; ²Boston VA Healthcare System, Boston, MA; ³Brandeis University, Waltham, MA. (*Tracking ID #1939008*)

NEEDS AND OBJECTIVES: In recent years, Boston University School of Medicine (BUSM) recognized a local need to develop a formal curriculum to teach teamwork. The BUSM curriculum committee simultaneously advocated for increased exposure to the arts and humanities throughout medical school training. In order to meet these needs, the BUSM fourth year Advanced Internal Medicine clerkship developed a new curriculum using Visual Thinking Strategies (VTS) to facilitate teaching teamwork skills. VTS has been shown to successfully teach observation skills but has been studied infrequently outside of teaching observation. Objectives of the curriculum include: *Identify characteristics of a highly functioning team *Listen actively and encourage ideas/opinions of other team members *Practice respectful dialogue and expressing differences in opinion *Explore conflict resolution skills in a group setting *Integrate viewpoints of all team members

SETTING AND PARTICIPANTS: The VTS and Teamwork curriculum was developed for the BUSM Advanced Internal Medicine clerkship, a mandatory four-week clerkship completed during the final year of medical school. The clerkship includes 1 day of classroom-based didactic teaching per week with a focus on teaching advanced communication skills. The VTS and Teamwork curriculum was inserted into these didactic sessions.

DESCRIPTION: Development of the VTS and Teamwork curriculum has been an iterative process with changes in response to student feedback. The curriculum was first implemented in June 2013, evolved over the next several blocks, and finalized in December 2013. The curriculum is divided into three distinct workshops: 1) Introduction to VTS and Teamwork: Speak up, 2) Listening as a Team Member, and 3) Listening as a Leader. VTS is a well-described process that involves the facilitated discussion of artwork to build skills in observation, communication, and listening. During a VTS session a trained facilitator guides learner discussion of a work of art using three questions: what is happening here? What do you see that makes you say that? What more can we find? Each workshop includes at least one VTS session. Additionally, two of the workshops include modified VTS type activities. The second workshop incorporates a small group activity to enhance listening skills. The third workshop uses a separate small group activity to allow students to practice the role of group facilitator. In addition, students also receive formal teaching on teamwork. The curriculum uses the model described by Amy Edmondson called 'Teaming on the Fly', which describes five attributes of highly functioning teams: speaking up, listening intensely, integrating different facts and points of view, experimenting iteratively, reflecting on your own ideas on actions.

EVALUATION: There are two methods of curriculum evaluation. First, the students complete a pre and post survey. Both surveys include the TeamSTEPPS - Teamwork Attitudes Questionnaire, a validated survey developed by the Agency for Healthcare Research and Quality to study self-rated attitudes towards teamwork. The change in score after completion of the curriculum will be analyzed. The post survey includes an additional set of questions to determine student perceptions of the curriculum. Second, the students take part in a focus group at the completion of the clerkship to further explore their attitudes towards the curriculum. The BUSM Institutional Review Board approved this study. Data collection began in late fall 2013.

DISCUSSION/REFLECTION/LESSONS LEARNED: Preliminary data reveal that students largely value the addition of VTS to their curriculum as a novel method of medical education. At times they struggle to link VTS with learning teamwork skills and continue to seek an explicit set of techniques to improve their teamwork skill set. A subgroup of students express striking discontent with the curriculum. A subgroup analysis is planned to attempt to determine unique attributes of students dissatisfied with the curriculum. Thus far it seems that using an art-based intervention to teach skills beyond observation alone is generally well received and valued by students. Future attempts to develop novel arts-based curricular interventions need to focus on an explicit connection between the activity and the clinical skill to be learned.

WELCOME TO THE NEIGHBORHOOD: TEACHING THE SOCIAL DETERMINANTS OF HEALTH Jada C. Bussey-Jones; Maura George; Stacie Schmidt; Jennifer E. Bracey; Mehul Tejani; Schuyler D. Livingston. Emory University, Atlanta, GA. (*Tracking ID #1934052*)

NEEDS AND OBJECTIVES: New physicians require broad medical knowledge and a practiced set of procedural skills. Training in these areas would suffice in decreasing disease burden if medical care were the only factor relevant to patient health outcomes. Research suggests, however, that multiple complex social determinants (e.g. neighborhood characteristics, social policies, and available resources) play a significant role in producing or mitigating health outcomes and racial/ethnic disparities. Studies suggest that fourth year students were no more knowledgeable about health care access than first-year students, and that students' attitudes toward the underserved become more negative throughout medical school. Further, most current educational environments do not prepare learners for engagement with broader health issues. This course was designed to 1) describe the complexity and impact of community and other social determinants of health on patient health outcomes, and 2) state ways, to connect community/public service and advocacy with learners clinical and academic work.

SETTING AND PARTICIPANTS: Emory University School of Medicine month long elective course available to interprofessional learners (nursing, medical, PA students) at Emory and Morehouse Schools of Medicine, as well as visiting students from outside institutions.

DESCRIPTION: Our curriculum uses a combination of didactic lectures, readings, experiential learning, direct service activities and personal reflection to equip future

physicians to practice medicine in a socially complex world. We help students better understand and cooperatively address the problems facing patients and communities. Examples of student activities include assessment of community resources such as green space, fresh vegetables, pharmacy supply, safety, tobacco, alcohol stores/billboards. Learners also participate in simulation experiences (e.g. navigate public hospital as a patient - assessing wait times, barriers, etc.). Participants engage with community partners' sites using an asset model approach to collaborate and participate in health related interventions. Our students also engage several essential community resources that provide context for the health of many of their patients including, homeless shelters, nursing homes, and prison medical facilities. Finally, they are trained asked to complete advocacy tasks such as visiting the state capital, meeting with legislators, writing letters to the editor or position papers. This course also utilizes several means of reflection including small group discussions, journaling, photo journaling.

EVALUATION: The course was evaluated in several ways 1. Learners' attitudes were compared to controls through use of Medical Student Attitudes toward the Underserved questionnaire (MSATU), a validated survey instrument administered at 0, 1 and 12 months. Our preliminary results reveal a significant difference in MSATU scores between controls and course participants at-month 0. However, there was no significant change in scores when comparing 0 to 1 month survey results within social med participants or controls. This suggests that there may baseline attitudes among self-selected participants that led them to this course. 2. Semi-structured interviews were completed at the end of the elective to characterize the learners and identify best received components of the elective. The curriculum was very well received, and we had a marked increase in the number of requested participants in the course over the 2 years of implementation. 3. Ongoing analysis is underway, including an electronic database for longitudinal analysis of elective participants.

DISCUSSION/REFLECTION/LESSONS LEARNED: This presentation will highlight the development and implementation of the Social Determinants of Health curriculum at Emory University School of Medicine. We will describe the core components of our curriculum, share tools, and discuss challenges. We will also specifically discuss strategies to forge relationships with community partners, collaborate with educational leadership to broaden our curricular impact, increase core faculty knowledge and expertise, and evaluate and modify curriculum. This elective seems to attract a selected group of individuals with positive baseline attitudes about caring for the underserved. Qualitative interviews suggest these positive attitudes were bolstered through service learning. Learners in our course expressed a desire for more social medicine concepts and didactics to occur earlier in undergraduate medical education. An increased number of learners and ongoing evaluation efforts will direct future course development and improve our understanding of the personal characteristics, qualities, and experiences that lead to positive attitudes about care of underserved and careers in community engagement, service, and health advocacy.

WORK-PLACE BASED ASSESSMENTS: LEVERAGING CLOUD-BASED MOBILE TECHNOLOGY FOR CAPTURING NARRATIVE COMMENTS
Churlson Han; Gary S. Ferenchick; David Solomon. Michigan State University, East Lansing, MI. (*Tracking ID #1939243*)

NEEDS AND OBJECTIVES: Direct observation and feedback are essential components of medical education. Immediate, specific feedback can be vital to learner development. Valued feedback is frequent, relevant to observed behavior, specific, and timely. The purpose of this exploratory study was to calculate the percentage of work-place based assessments, completed with a Cloud-based mobile just-in-time evaluation system (i.e. JIT, described below), that included any written comments (i.e. comment-enhanced evaluation); and to calculate the percentage of comments that were general, specific, or specific with detail, regarding students' clinical performance; and to describe evaluator variables affecting comment specificity.

SETTING AND PARTICIPANTS: Between July 2012 and September 2013, 256 students at Michigan State University's College of Human Medicine were required to obtain ten directly observed evaluations. Using JIT, all evaluator comments were electronically captured in a permanent, cloud-based record, and were subsequently coded on three levels: general ("Good physical exam skills" or "Practice more"), specific ("Excellent neuro exam" or "Better organization"), or specific with detail ("Listened to axilla for radiation" or "Percuss lung fields & compare sides"). Evaluators were not provided any training on providing narrative comments. Three raters independently coded all narrative comments after establishing inter-rater reliability.

DESCRIPTION: We developed, implemented and assessed a Cloud-based clinical evaluation application (i.e. Just In Time Medicine or JIT) for internet-enabled devices

including smart phones, which displays customized competency checklists for 17 CDIM training problems for evaluators to use when implementing work-place based assessments of students' clinical skills in authentic clinical settings. JIT includes discretionary sections for evaluators to provide narrative written comments pertaining to: 1) "one area the student did well" and 2) "one area the student can improve upon".

EVALUATION: 2658 CEX assessments were completed among the 256 students, with 227 students (88.7 %) having at least one comment-enhanced evaluation. The range of comment-enhanced evaluations per student was 0–11, with an average of 4.9. Out of a total of 1285 comments, 288 included only "well done" comments, 44 included only "needs improvement" comments. Nine hundred fifty-five included comments for both. For "well done" feedback, 17.2 % were general, 57.2 % specific, and 22.7 % specific with detail. For "needs improvement" feedback, 14.8 % were general, 53.4 % specific, and 31.8 % specific with detail. Resident feedback was compared to faculty. For "well done" comments, faculty feedback was 28.0 % general, 56.0 % specific, and 16.0 % specific with feedback, while resident feedback was 18.2 %, 58.4 %, and 23.4 % respectively. For "needs improvement" comments, faculty feedback was 11.5 %, 50.3 %, and 38.2 %, while resident feedback was 16.4 %, 55.3 %, and 28.3 % respectively.

DISCUSSION/REFLECTION/LESSONS LEARNED: When directly observing and assessing learner performance in authentic clinical settings, we determined that written comments accompany a high percentage of evaluations using Cloud-based technology delivered via mobile devices. These comments provide a high level of specificity. Evaluators displayed more detailed feedback for "needs improvement" items. We did not observe any variance in "well done" comments between faculty and residents, but faculty provided more specific with detail feedback on "needs improvement" items. This use of technology to capture narrative comments can provide specific and relevant student feedback.

WORKING TOWARDS MEANINGFUL RESIDENT INVOLVEMENT IN QUALITY IMPROVEMENT AT TWO UNIVERSITY CONTINUITY CLINICS Danielle F. Loeb; Susan M. Nikels; Rachel Swigris; Suzanne Brandenburg. University of Colorado Denver, Aurora, CO. (*Tracking ID #1938666*)

NEEDS AND OBJECTIVES: The ACGME requires that "residents are integrated and actively participate in interdisciplinary clinical quality improvement (QI) and patient safety programs." In 2012 we initially introduced a QI curriculum in the ambulatory setting for all interns. Summative assessment by QI faculty and leadership revealed that lack of faculty exposure to QI principles and a non standardized approach to project organization led to high variability in project quality and resident involvement. The objective of this project was to improve integration of interns into QI projects in their continuity clinic settings.

SETTING AND PARTICIPANTS: This educational innovation took place in two resident ambulatory internal medicine clinics associated with one university hospital. It included 19 interns in the two clinics.

DESCRIPTION: Drawing on our prior experience and a literature review of best practices, we developed a combined didactic and experiential curriculum (Figure 1). The primary improvements include: 1) IHI (Institute for Health Care Improvement) QI curriculum required for interns and QI faculty 2) Each intern developed a personal QI project to practice fundamental QI skills 3) Interns integrated into designated clinic team QI projects 4) Dedicated FTE for QI faculty to lead clinic team QI projects 5) Personal QI projects will be reviewed with a standardized evaluation including: SMART aim statement, outcome measures, systematic data collection, PDSA cycle completion, presentation of data, and completion of IHI curriculum. 6) Each intern will submit summary of team QI project including: SMART aim statement, literature review, fishbone diagram or process maps, outcome measures, and PDSA cycle completion. Figure 1. Quality Improvement Curriculum by Calendar Month July ■ IHI Open School (IHI OS) QI 101–103 completed through GME August ■ IHI OS QI 105: The Human Side of QI ■ Completion of QIKAT Pre-test September ■ Create Personal Improvement project ■ Conduct Personal PDSA cycle October ■ Review concepts from IHI OS QI 101 ■ Begin to compile list of possible QI projects November ■ IHI Open School QI 102 and 103 ■ Choose QI projects (determine teams, etc.) December ■ IHI Open School QI 104 ■ Start project charter ■ Determine clinical team dedicated to mentor project January ■ Review project charter with faculty, revise PRN ■ Create Aim Statement February ■ Review Aim statement with faculty, revise PRN ■ Determine sources of data ■ Start SIPOC analysis March ■ Revise SIPOC analysis ■ Start drafting Fishbone or Process map April ■ Define metrics ■ Propose PDSA cycles May ■ Conduct PDSA cycles (if possible) June ■ Submit QI H&P and Reflection summary to MedHub ■ Create "Next Steps" Summary ■ Present to Clinic

EVALUATION: To date, 10 of 19 interns have presented personal QI projects with satisfactory review. These will be completed by February 2014. Of those who have presented personal project, all have satisfactorily completed their SMART Aim statement, balancing measures, systematic data collection, graphed results, PDSA cycle completion for their personal QI projects. Interns have completed 88 % of their assigned IHI modules. The interns will start integration into clinical teams in February with completion of team QI summary report in June 2014.

DISCUSSION/REFLECTION/LESSONS LEARNED: The primary lessons learned include: The didactic curriculum should be offered in conjunction temporally with the

experiential curriculum (personal QI project) • Supervising faculty for QI projects need adequate education in QI • Residents should be integrated into projects that align with clinic goals to ensure dedicated QI faculty time and other support needed for success • Flexibility and willingness to adapt on the fly are important approaches to implementing new curricular elements in clinical settings In conclusion, involving residents in QI continuity clinic projects offers important opportunities to integrate them into their clinics while providing them with essential QI skills. Steps toward achieving meaningful integration include providing faculty and resident didactics, offering an experiential curriculum and securing support for key faculty supervisors.
